"THE WORLD'S STANDARD PHOTOGRAPHIC REFERENCE BOOK."
"THE PHOTOGRAPHER'S GUIDE, PHILOSOPHER, AND FRIEND.'

British Journal Photographic Almanac

And Photographer's Daily Companion for 1897.

The Most Complete Photographic Reference Book ever published, and the Largest Circulation of any Photographic Annual in the World.

1,384 PAGES.

THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC and Photographer's Daily Companion is recognised throughout the world as the most practical and valuable of all the Photographic Annuals, its popularity being so great as to provoke numerous imitations. Its pages teem with able Technical Articles, the results of the experiments and experiences of the foremost authorities in photography. It is the one indispensable and trustworthy reference-book of the Professional and Amateur. No Photographer should be without it.

OPINIONS OF THE PRESS.

'*The British Journal Photographic Almanac* is as welcome and compendious as ever. It is, as usual, crammed with standard and with current notes upon everything photographic worth alluding to. It is charmingly illustrated by various typical photo-printing processes, contains full descriptions and diagrams of several varieties of animated-photograph apparatus, and a number of new and acceptable features.'
Croydon Advertiser.

'*The British Journal Photographic Almanac* is one of the works on photography that no one in the business can well do without. It contains information of great value, which can be found nowhere else.'
Mona's Herald.

'The Proprietors of the *British Journal of Photography* have once more published their well-known "Photographic Almanac and Photographer's Daily Companion." It forms, as heretofore, a solid volume entirely devoted to photography and to matters dealing thereon. The volume has been prepared under the editorship of Mr. Thomas Bedding, and is published by Henry Greenwood & Co., 2 York Street, Covent Garden.
Daily News.

'*The British Journal Photographic Almanac*, 1897.—This year's issue is a bulky volume running to 1400 pages. Of course, a large number of these are devoted to advertisements; but, besides these, the literary matter is of such an extent and contains such a mass of information, as to make it well worthy of the claim contained in the sub-title of "Photographer's Daily Companion." We have not space to enter into a lengthy review, but we feel sure that no one who is interested in photography, either as an amateur or professional, will fail to obtain from its pages a great variety of useful practical hints.'—*British and Colonial Druggist.*'

'*The British Journal Photographic Almanac for* 1897. Edited by Thomas Bedding, F.R.P.S.—We have to congratulate both editor and publisher on the production of this ponderous tome. It contains the usual collection of miscellaneous articles by various writers, upon almost every conceivable photographic topic, and from the pen of the Editor is an extremely useful article on "Modern Photographic Lenses," which gives just the necessary data that a practical photographer wants, but when added to this there is a very good collection of "Practical Notes and Suggestions of the Year,' besides the enormous number of advertisements, which in themselves form a cyclopædia that is alone worth the money, it will be seen that this book should be the constant reference and friend of every photographer. It is also sold bound in cloth.'—*Photographic News.*

'This very bulky volume contains a record of photographic progress during the year, articles upon many subjects of current interest and improvements to the photographer. Reproductions are also given of some very beautiful specimens of work. There are, of course, a very great many pages of advertisements, but their very completeness adds to the value of a technical annual such as this.'—*Bristol Mercury.*

'We can confidently recommend to our photographic readers the 1897 issue of *The British Journal Photographic Almanac* as surpassing all previous emanations from that source. The frontispiece, "Child Study," is as perfect a specimen of picturesque portraiture and bromide printing as one could wish to see. The articles are both numerous and exhaustive, thoroughly up to date with regard to all improvements in photographic science, embracing "Radiography," the Kinetoscope, acetylene gas, and the much-neglected stereoscopic work, together with a special chapter on modern lenses by the Editor. The ground covered by that devoted to "formulæ" is very extensive, and certain to meet the necessities of all classes of photographers. Altogether the *Almanac* is a complete summary of everything of service to the photographer promulgated during the past season.'—*Horse and Hound.*

'The Almanac for 1897 of the *British Photographic Journal*, which has just been issued, is fully as bulky as any of its predecessors. As usual, it contains a very interesting summary of the year's work in the "black art." There is an informative article on modern photographic lenses, and a large number of contributed papers, which should prove of service to amateur and professional photographers alike. The almanac is illustrated with a series of pictures produced by various processes.'—*Glasgow Herald.*

'In the *British Journal Photographic Almanac* lovers of the camera will find much interesting information relative to their art. It is certainly a work which no amateur should be without.'—*Daily Telegraph.*

'The 1897 *British Journal Photographic Almanac and Photographers' Daily Companion* is now obtainable. To amateurs and professionals in the art the *Almanac* is of great interest and use. The number of articles in the book this year is increased.'—*Sunday Times.*

'*The British Journal Photographic Almanac.*—This bulky volume makes its appearance pretty much in the guise it has assumed for a number of years. It is full of good things. The summary of the year is brief but pithy. The editor deals with photographic lenses in a paper of some length, which is illustrated and which is most interesting throughout. There are papers also by well-known writers. The 'Epitome of Progress in 1896,' compiled by the Editor, is a very creditable and painstaking piece of work—and of its value there can be no doubt. 'Patented Inventions of the Year' is also valuable and useful, as is 'Practical Notes and Suggestions of the Year,' and 'Recent Novelties in Apparatus.' There are numberless tables and formulæ, list of societies, and other matter that make it one of the cheapest and best photographic books of the year. The price is 1s. paper, and 1s. 6d. cloth.'
Photography.

'*The British Journal Almanac* makes its first appearance under the able editorship of Thomas Bedding, F.R.P.S., and many of its old readers will scan it the more narrowly on that account. The book will bear such inspection, for though it shows considerable changes, they are judicious, and in the right direction. The miscellaneous articles occupy rather less space than before, but the editorial contributions, records of the year's progress, &c., are correspondingly longer. This, in a year which has seen the development of radiography, kinetography, and acetylene, as well as a great advance in the use of anastigmatic lenses, is decidedly an advantage.'—*The Photogram.*

'*The British Journal Almanac for* 1897. Obesity is a disease in man, but an admirable quality in almanacs, and so we are glad to see the familiar yellow-backed annual, if anything, looking fatter and healthier than ever. In 1871, as far back as our set goes, it was less than half the size of the present issue. The contents are as good as ever, the introductory summary and the editor's article on recent lenses being particularly valuable for reference.'—*Practical Photographer.*

THE BRITISH JOURNAL OF PHOTOGRAPHY.

No. 1861. Vol. XLIII.—JANUARY 3, 1896.

Contents.

EX CATHEDRÂ.

These lines are being written within a very few hours of the time when people take the opportunity of making good resolutions and coming to the more or less desirable determination of turning over a new leaf. It is an old saying that, at midnight on the 31st of each December, if the operation of turning over the new leaf were accompanied by the sound usually characterising the material action, the world would be filled with the noise of a tremendous rustling of paper. What a merciful thing it is that those new leaves do not rustle, and that most of us, therefore, are spared the subsequent reproaches of our neighbours, as well as of our consciences, that we rustled our leaves in vain!

* * *

With this, the first number of the new year, The British Journal of Photography turns over a new leaf, in the simple sense that it appears before its readers in a changed and, it is thought, improved aspect. What is technically known as the "make-up" of the paper has been rearranged, and throughout its pages it will be observed that several alterations of a minor character have been introduced. It is believed that those alterations will meet with the approval, as well as consult the convenience, of our readers, who in the course of two or three weeks will have opportunities of becoming acquainted with other changes in detail which it is proposed to adopt.

* * *

As regards the future of the Journal, it is perhaps needless to state that it will be the aim of those in whose hands its destinies are placed to maintain it in the proud and honourable position it has so long occupied. The various able writers who for many years past have well and loyally contributed to and supported The British Journal of Photography under past occupants of the editorial chair will continue their valued services under the present Editor-in-Chief, who has also the satisfaction of stating that he has secured the co-operation of several accomplished experimental and practical photographers of the younger school, who will supply just so much of what is called the "new blood" that it may be found desirable to introduce into these columns.

* * *

For the rest, while the Journal will follow the lines to which its lengthy and successful career and the confidence and good opinion of the photographic public at home and abroad have given the stamp of approbation, it is our intention to make use of and develop certain new features which have been chosen with the view of augmenting its value. Abiding by precedent, however, we refrain from publishing a programme. We are, indeed, content to state that it is our design to omit no effort for assuring to The British Journal of Photography a continuance of the prestige and influence it has so long possessed, that all departments of photographic theory and practice will be found fully dealt with in its columns, that the artistic aspects of photography will, as hitherto, be discussed by representative writers, that the trade, the manufacturers, and professional photographers will continue to find in the Journal an earnest and unwearied mouthpiece—in short, that everything which tends to promote photographic advance and progress will have the fullest and earliest recognition in its pages.

* * *

Innumerable readers and friends of the Journal will also, doubtless, be interested to know that the old editorial office at York-street, which has long been looked upon as the one spot

to which so very many of those, from abroad as well as at home, who are interested in photography sooner or later resort, has been swept and garnished, and by-and-by may not improbably present a quite palatial appearance. To that office all friends of the JOURNAL and those to whom we may possibly be of help or assistance in photographic matters will always, as in past times, be cordially welcomed.

* * *

FINALLY we pass on to remark that it is the intention to make this weekly *causerie* the opportunity of indulging in an informal—possibly a pleasant, and, it is to be hoped, instructive—gossip with the reader on such topics of interest as may seem profitable to select for discussion or comment here. The only remaining observation called for is, that whatever is said in this part of the JOURNAL appears under the same sense of responsibility as that which accompanies the remainder of its contents.

* * *

WHILE the Christmas atmosphere still to a great extent lingers with us, it may be worth while noting that photography appears to be responsible in a larger degree than in previous years for the production of portions at least of the Christmas and New-year's cards that have been so prolific during the last few days. The cheapness, convenience, and adaptability of the collotype process has at last been thoroughly grasped by the wholesale houses, and an enormous number of such cards have been distributed. In the collection of which we were the fortunate recipients, bromides and platinotypes also figured. For the last two kinds there is still scope for business which, we fear, many a photographer in a small way neglects. If anything is likely to drive the old-fashioned coloured product into complete oblivion, it is photography in some form or other. Have photographers yet grasped that fact?

* * *

SILVER prints—that is, surfaced prints—as Christmas and New-year's cards seem, on the other hand, to be going out of vogue. We received one such, however. It was a portrait of ourselves, taken in this office by Mr. W. Crooke, of Edinburgh, who used a Pocket Kodak, and gave an exposure of twenty seconds. The result was capital. The Pocket Kodak has, apparently, had an enormous run, which will probably not be exhausted during the approaching season. The examples of interior and portrait work, which Mr. Crooke showed that he had done with it, do the little instrument and Mr. Crooke great credit.

* * *

MR. ALFRED MASKELL, who has constituted himself the advocate of the Artigue non-transfer method of carbon printing, writes with reference to an article on the subject that was recently published, and says, "I note the leader which says that 'if the transfer operations could be dispensed with, and the image developed—*provided the gradation of tones were perfect*—direct on the pigmented paper, the carbon would be the simplest and most easy of manipulation of all the printing methods.' With Artigue's or similar methods the transfer *is* dispensed with, the gradation of tones *is* perfect, and the image is as sharp as by any other process, and the image is not reversed as regards right and left. The small picture which I showed you, and which was done by Pringle, and others which Sinclair made on the Artigue paper with the greatest ease on his first trial, are very good examples of the incorrectness of the above statements."

* * *

THE last Exhibition of the Salon contained, as Mr. Maskell has already pointed out, many examples of prints by the Artigue process, to which, on the ground of technique, no objection could be taken; while as regards the particular print to which he refers, it struck us as so good of its kind as to be fairly comparable with ordinary carbon or platinum prints. We have not tried the Artigue paper, but there seems no obvious reason why it should not be popular, at any rate among amateur carbon printers. The specimens shown at the Dublin Convention elicited at the time warm praise from the late Editor of the JOURNAL.

* * *

UNDETERRED by the fate of most dramatists who take photography as a base upon which to build a portion of their plots, two gentlemen lately essayed success where so many have failed, and, like poor Mr. Jerome the other day, came to grief. These gentlemen called their piece *An Unsanctified Garment*, which article of attire, according to a contemporary, was "a short dress worn at a fancy ball at Covent-garden by my Lady Arlington, who, thinking she would like to be photographed in it, forwards it to the portrait-maker, Mr. Hammond, who, judging by his appearance and his surroundings, is the sort of photographer who does business in the summer time on Ramsgate Sands. Of course she makes an appointment, but she does not keep it.

* * *

"LORD ARLINGTON looks in while Mrs. Hammond is masquerading in the costume, and persuades her to be 'taken' with him. When he is gone, the giddy Mrs. McDouglas, wife of one of the strait-laced elders at Mr. McMuggin's tabernacle, appears on the scene. She, too, dons the 'unsanctified garment,' and she, too, is 'taken.' She is 'taken' more than she wanted to be. She bargains with Hammond to take one picture only, and then to destroy the negative; but Hammond's assistant, who has a grudge against the over-pious Solomon McDouglas, uses the camera on her while she is pinning up her skirts and exposing a well-developed calf, including also in the picture Lord Arlington, who has suddenly returned for a jewel he has left behind. The assistant, having developed his plates, puts the results in his master's window, and then Solomon McDouglas's troubles begin," &c.

* * *

THIS kind of thing was put forward as the pivot upon which a "serious" piece of dramatic work was supposed to turn. The authors entertain curious notions as to the way in which the business of photographic studios is conducted.

* * *

WE conclude as we should have commenced, and that is by wishing all readers of the JOURNAL A Happy and Prosperous New Year.

THE FUTURE OF COLLODION AND GELATINE IN PHOTOGRAPHY.

IT is now just about a decade and a half since gelatino-bromide emulsion plates superseded wet collodion for general com-

mercial work, and dry collodion amongst amateurs. Ever since that period attempts have been made by experimentalists to produce, with collodion, plates as sensitive as with gelatine, and, from time to time, it has been alleged that some one has accomplished that end. It will not, therefore, be amiss, at the commencement of the year 1896, to consider what would be the prospects of success, commercially, of collodion dry—or even wet—plates, provided they could be produced of the same rapidity as that of the present brands of gelatine plates. This it may be the more desirable to do, inasmuch as we have heard several rumours during the past year or two, particularly from the Continent, that the thing is *un fait accompli*, but that is all; results up to the present have not been forthcoming.

The fact is, that, because a thing may be desirable at one period, it does not follow that it will be so at another—or at least to the same degree—may be the case with the subject now under consideration. There is no question that, when gelatine displaced collodion for general work, it did it solely by reason of its superior sensitiveness, and that alone. The qualities and the character of the negatives were not liked, indeed were strongly condemned, for a time, by those who, perforce, used them simply on account of their enhanced rapidity over the wet-plate process. There is no question that if at the time referred to collodion could have been made to yield plates equalling the rapidity of gelatine, the latter would never have assumed the proportions it has in photography.

Collodion dies hard, and its makers tell us that there is still a constant and steady demand for it in various directions. In photo-mechanical work it is yet the favourite process for the negatives. Although specially prepared plates are being employed by some, many of the leading houses still adhere to the old process, and they affirm that it suits them best. When enlargements are made through the medium of a large negative, as in the carbon and platinotype processes, wet collodion is almost universally employed. On the Continent most of the art-reproduction work is done by collodion. The majority of the commercial lantern slides are still made on wet collodion; and not an inconsiderable proportion of the best of those by amateurs on collodion emulsion. Seeing all this, it is really worth considering whether, supposing it were possible to produce collodion plates equal in rapidity to gelatine, they would now stand any chance of superseding it. The answer is difficult, because the conditions are so widely different from what they were when the former process ousted the latter.

At the present time the standard of negatives has changed, and the old wet-plate character—the ideal of the older workers—is no longer desired; indeed, it would be decried by the majority of modern workers. Again, the present generation of photographers, as a rule, knows nothing about the manipulation of collodion, either by acid or alkaline development. Moreover, the tenderness of the collodion film, as compared with that of gelatine, would give trouble to many, as would also the general delicacy of the manipulations from first to last. Gelatine plates will bear a deal of rough treatment, while collodion must be tenderly handled. It is a little doubtful even if some of the older workers would again take kindly to collodion. Taking all these facts into consideration, one cannot but arrive at the conclusion that, if collodion could be rendered as sensitive as gelatine for negative work, it would have an up-hill journey for some time before it would oust gelatine from the field for that purpose. The character of the negatives it yields—the standard of fifteen years ago—would not assist it much in the eyes of modern workers, except those connected with the photo-mechanical processes.

These remarks, be it understood, are not made to deter experimentalists, but rather to stimulate them, for, as every one knows, the gelatine process has its shortcomings, and any other that would avoid them would be a desideratum. One thing, by way of encouragement, may be mentioned, which is, that collodion lends itself better to orthochromatic photography than does gelatine. Some orthochromatic collodion plates give far better colour renderings, without a colour screen, than do gelatine ones.

Turning now from negatives to prints, one may as well first glance at the future prospects of gelatine and collodion for printing purposes. During the last few years gelatine has largely displaced albumen for printing-out papers. Now the old collodio-chloride process of thirty years ago is being vigorously resuscitated, here and in most other countries, and it remains to be seen if it will eventually, in time, oust gelatine as gelatine did albumen, as some are sanguine enough to predict it will. That both gelatine and collodion papers have their failings as well as their advantages, there is no gainsaying, and what process of photography, it may be asked, has not? It would, however, be rash to speculate on the subject as to the future, beyond saying that it will be a case of the survival of the fittest.

The Uses of Acetylene.—The new illuminant continues to attract popular and scientific attention. We note an account of a method of removing phosphine from the gas obtained from the new source, calcium carbide. The gas, as is known, can be liquefied, and when allowed to evaporate in air it solidifies. The solid melts at 81°, and the liquid boils at 83°. From what may be termed technical quarters, we are led to expect its practical application to illumination purposes, and that indeed a revolution in domestic illumination is at hand. We read that "the advantages of this form of illumination are evident, for the gas in a liquefied form can be used in places where no gas supply exists. Street mains are thus unnecessary, and a light of extraordinary power is placed at the disposal of any one, the price of acetylene being less than ordinary gas." We should understand the latter rather startling assertion to mean that the price is less candle power for candle power. At the same time it should be remembered, and is not usually remembered, that the high price we pay for coal gas is mainly composed of what we may term cost of delivery. If it were feasible to do it, it would pay gas companies to deliver gas at their works at pence rather than shillings per thousand.

Light Action on Eruptive Diseases.—Most of our readers are familiar with the old photographic story of the sitter who could not be satisfactorily photographed because of a series of dark markings which made their appearance on each positive almost as soon as the developer was applied, the sequel of the story being the fact the sitter was unknowingly affected with the first stages of an eruptive fever, the spots of which were perceived in their inchoate stage by the camera before they could be observed by the eye. We have never met the photographer who acted on this occasion, nor is his name handed down to fame; but a still more remarkable connexion betwixt the sun's rays and disease is to be found narrated in a recent number of the *British Medical Journal*. Several investigators have shown that an inflammatory action is produced on the skin by radiations of short wave-length, and hence, when an inflammation already has started, it is reasonable to suppose that it would be increased by such light-waves. Dr. N. R. Finsen, of Copenhagen, describes, in the journal mentioned, his results with small-pox patients confined in a room lighted entirely after the manner of a photographic dark room. The window glass is to be

deep red, or, if curtains are to be employed, several thicknesses must be hung. The treatment must be begun at an early stage, and continued till the vesicles are dried up, and the results are satisfactory.

The Decomposition of Hypo by Acids.—It is known, in practice, by photographers who lay claim to no special chemical acquirements, that upon adding an acid to hypo a milkiness of the solution is gradually superinduced. Thiosulphuric acid is liberated and spontaneously decomposes, and sulphur is deposited. How this action takes place is a disputed point amongst chemists. A contribution towards its elucidation, which must be valuable to students of the theory of the fixing bath, has been made by M. Arnold F. Holleman, and published in *Comptes Rendus*. What is termed the molecular theory, *i.e.*, the production of water, sulphurous acid, and sulphur, is objected to, on the ground that the action should be greatest at the outset when the concentration is at a maximum, but this does not appear to be the case.

Then Spring suggests that the interval that elapsed after the addition of acid, before precipitation takes place, is caused by reaction between the sulphurous anhydride and sulphuretted hydrogen, produced by secondary action; but M. Holleman points out that the precipitation will take place in the presence of a lead salt without darkening taking place, which quite negatives the idea of the presence of sulphuretted hydrogen. He suggests the true explanation of the apparent tardiness in the production of the sulphur precipitate is that the separation of the sulphur takes place at once, but needs time before the particles agglomerate sufficiently to become visible. We would like to point out, in this connexion, a hitherto unexplained phenomenon in photographic practice.

It is well known that the addition of alum to hypo solution leads to the usual sulphur precipitate; but, if a gelatine plate, saturated with hypo, be rinsed very slightly and placed in alum solution, as is done when frilling is anticipated, no milkiness is produced within the film. M. Holleman's theory would explain this phenomenon. The sulphur may be precipitated, but not in a visible form, and there will be little freedom of motion in the molecules of sulphur; they may exist in the film, but fail in consequence to become agglomerated. Something of a similar nature may take place during the fixing of albumen and other prints; the ultimate reaction of such minute particles of sulphur and the coloured salts of the film can be matter of speculation only.

DIGRESSIONS.

I.—Imitation.

The title of this paper covers two kinds of imitation—the imitation of nature by the artist, and the imitation of the work of the artist by the copyist or plagiarist.

There is still a great deal written of the "Stick to nature, my boy" order. This is a survival from the time when it was much more difficult to represent the facts of nature than it is now. Before the discovery of photography there was not much danger of getting too close to nature in any art; but photography soon showed that it was possible to make a picture which more nearly represented the facts of nature than anything that had ever been dreamed of, and yet having in it no art at all. The minute imitation seen for the first time in the early photographs afforded us agreeable surprise, creating pleasure in the mind; but it was a similar pleasure to that we derive from seeing a clever juggler, rather than that we obtain from viewing a work of art, to which may be added the delight and curiosity of seeing a new thing, and admiration for the scientific knowledge that could produce such a wonder. Times have changed. Curiosity in ordinary photographs is no longer excited, and the necessity for scientific knowledge is reduced to a nothing, or, at any rate, is much attenuated.

From a highly and skilfully finished painting—one that is really a minute copy of the facts of nature—although it may not have any pretence to poetry or sentiment we get another kind of satisfaction. We admire the dexterity of the artist's hand and the power he shows of seeing vividly both form and colour. But we must know that it is a deception before we can enjoy it; it must be a gentle surprise, and not a delusion. The deception must not amount to what is vulgarly but expressively called a "sell." Deception offends us, or suits only the lower or uneducated nature. A waxwork figure does not excite such pleasurable or elevated emotions as a marble statue; yet we know that, in the hands of a clever modeller, a wax figure can be made so nearly to represent nature as to be absolutely deceptive. I have run against one myself and begged its pardon.

Now, although the marble may imitate Nature, there is no attempt at deception. As Mr. Ruskin puts it, "A marble figure does not look like what it is not; it looks like marble and like the form of a man, but then it *is* marble and it is the form of a man. It does not look like a man, which it is not, but like the form of a man, which it is."

It may be said that the pre-Raphaelites of between 1848 and 1860 created wonders of art with more minute imitation than had ever been known in paint. So they did. But one of the sources of delight was in the skill and patience shown in such minute finish, and the success lay in the fortunate chance that the experiment was undertaken by enthusiastic young men of genius, and the novelty, intensity, and power of their pathetic subjects. In short, the thing said was eminently worth saying, and the saying was said as it had not been said since the time of the early German and Flemish masters between 400 and 500 years ago. Astonishment was one of the causes of admiration, but surprise was accompanied by other qualities, such as splendid colour and expression. The combination of the power of expression, colour, and minute fidelity to nature in these pictures was so extraordinary that no suppression or subordination was required to lead the eye to the principal parts. There are superfine art critics now who will go into raptures over a few scratched lines on a copper plate who would not allow that the art of which I have been writing was art at all. But, in my humble opinion, there has not been such great art produced this century as Millais' *Ophelia* and *Huguenot*, and Hunt's *Claudio and Isabella*. I still have the pleasure of occasionally sitting in the room in which the *Ophelia* hangs, and am never weary of its wondrous beauty.

It may be claimed that the early photography suggested this excessive study of nature. It probably did; but it was only a suggestion. The best men worked entirely from nature; their imitators took to copying photographs, and then came degeneration, for copying is a different thing from imitation aided by genius, pre-Raphaelite paintings' only merit became very like nature, and "very like nature" has never been enough in itself to make an endurable picture, whether in paint or any other medium.

It is true that nature must be imitated, but it is of little use if the man who turns the handle of the box of music has not the singing voice.

One reason why imitation is contemptible, as Ruskin calls it, is that it is easy. He says: "To the ignorant, imitation, indeed, seems difficult, and its success praiseworthy; but even they can by no possibility see more in the artist than they do in a juggler, who arrives at a strange end by means with which they are unacquainted, and juggling implies more ingenuity in the artist than a power of deceptive imitation." Now, photography gives incomparably the greatest amount of power of minute imitation or copying with most ridiculous ease, and it has lost the power of surprising us with its fidelity, for the detail of a photograph is one of the most ordinary objects of civilised life. Neither does the skill with which the minute finish is attained now affect us; we now recognise that the skill necessary to produce the cleanest, minutest, and most sparkling work is as minute as the work itself, and not to be considered in the result. That there is a skill and a use for technics far beyond those usually employed is also beginning to be recognised. It is not a technic that can be logged down in a text-book, but to use this technic necessitates a knowledge of art, the elements of which only can be taught, and it is this "world beyond" that must attract the photographer if he wishes to attain to, or remain on, the higher level. In future the photographer must no longer trust to the last moment for sufficient time to allow him to produce his masterpiece for exhibition. He must now take time to work up a favourite subject, or

realise a beloved idea, and tax his powers to the utmost, spending as much time upon his effort as he feels is necessary to bring it to as near perfection as his energies will allow; and, above all, if the result does not come within measurable distance of his ideal, to destroy it remorselessly. I am sorry to have to add that, the more progress he makes, the further he sees, the more of his work he will destroy, to which fact—without claiming to see further than others—I am a painful witness. I happen to be the possessor of the mortal fragments of a large, and, I thought for a time, important photograph, on which I had worked for months, and only destroyed after it was framed and ready for the last Salon.

Now we come to the imitation of the works of one artist by another.

It is a moot point how far one artist may imitate—I don't mean exactly copy—another, and yet feel that he continued honest, morally and legally, and, supposing he decides to sail near the wind legally, how near he may go, and still be able to look a brother artist in the face without blushing.

This question of imitation is a delicate and difficult problem. In a learner it may be a merit, in a master a crime. But how are we to estimate it when an artist imitates himself, and does it always? We can only say he becomes a manufacturer. Yet, again, we should be sorry if some artists forsook their own delightful style.

Apart from its morality, the value of imitative work depends a good deal on circumstances. If it is the work of a very young man, it may be, educationally, praiseworthy, and may be tentatively called promising, especially if he shows his taste by selecting a good master to imitate, or even a good school; his copying has not become sinful yet, and he has time to become more original. It is the constant imitation by mature artists that should be one of the unforgivable sins. This is especially true in photography, in which art the mechanical execution of an imitation is a negligible quantity. It is the original thought, plan, treatment, style that constitutes the merit.

Imitative work is interesting, to a certain extent, to the producer—he learns something by producing it—but is worth little to the world; it is but as an oleograph to a painting. Do we thank the man who bores us by feebly whistling over a sonata he had just heard played by Paderewski? There is even merit in imitation when properly used. It is better for the student if he is *not* troubled with too much originality during his noviciate; it distracts his thoughts from the work suitable for his studentship; but he should not show his imitations as his own original work. This, I am afraid, is constantly done in photography.

It is not meant that ideas, hints, and suggestions should not be picked up from the works of others. Imitation, if it is imitation, of this kind is allowable. As the poet says,—

> "Who solely on his own resources draws
> Lives like a bear by sucking his own paws."

On the other hand, it is a mistake to go too far; it is well to weigh the question carefully, How much may be stolen? As Peter Pindar said to Gainsborough when he copied Snyder's dogs into one of his own pictures:—

> "I do not blame thy borrowing a hint;
> For, to be plain, there's nothing in't—
> The man who scorns to do it is a log:
> An eye, an ear, a tail, a nose,
> Were modesty, one might suppose;
> But, zounds! thou must not smuggle the whole dog."

There is yet one other kind of imitation that must be mentioned. I mean the imitation of one kind of art in the materials of another. This has always been a bone of contention among artists. Ghiberti was greatly censured for treating his wonderful bronze gates at Florence more in accordance with the principles of painting than with those of sculpture; but this did not prevent Michael Angelo saying they were worthy to be the gates of paradise. Then, we sometimes see sculpture imitated in paint, and the result is only fit for the entrance to a circus or penny gaff. Some years ago the critics found that water-colour drawings began to look as rich as oil paintings, and cried out accordingly. The alteration of a word set everything right: the artists called their "drawings" "paintings." Simple are the ways of genius; the critics were content.

Some photographers have been accused of imitating sepia drawings. I don't think this has been intentional. The art is in a transitional state, and, if in the search for perfection the results of one art have looked for a moment like those of another, it surely may be excused. When I get short of defensive argument, I like to think of a little incident of years ago. When specimens of Adam Salomon's wonderful portraits were first brought to England, a dear friend of mine worshipped them, as, indeed, did all of us. Not the mildest word of adverse criticism was allowed. You had to look and wonder. One day I ventured to humbly suggest of one of them that, perhaps, a straight line from corner to corner, cutting the space into two equal triangular halves, was not quite the best composition the subject allowed. I was answered sharply, "Perhaps he was working in that direction." Therefore it must be plain that the critic must know what the artist meant before he ventures to comment upon what he has done.

H. P. Robinson.

BY THE WAY.

It is not until we sit down to a little bit of quiet retrospect that we can really recognise how greatly things have changed in the course of a few years, and then, as we realise the vast difference between then and now, a feeling of wonder rises that we are not ourselves more changed. Thus, taking up the volume of the Almanac published just twenty years ago, I find the list of photographic societies in the United Kingdom comprises eight, all told, including the two London ones, with a total of seventy-nine meetings between them in the year. Going a little further into the matter, I find that a single individual, endowed with ordinary health and energy, and who, like myself, desired to keep thoroughly *au fait* with what was going on, could, with the exception of one meeting a month, have attended the whole of them, and still have had a clear half of the month unoccupied. Now, looking into the present year's volume, the list of societies in the metropolitan district alone exceeds fifty, and, in the three kingdoms, has swelled to the enormous total of nearly 300, while the number of meetings in the course of the year is altogether beyond my powers of calculation.

The modern enthusiast, who in London and some of our larger cities can find some photographic entertainment for almost every evening of the week, must find it difficult to realise how he would have felt when the "usual monthly meetings" of his Society—or, in the case of favoured Londoners, of the two Societies—were all he had to look to, beyond his own resources and the two existing journals, for his photographic sustenance; the chances of communion with a kindred spirit were, except in localities where two or three amateurs happened to reside within a day's journey of one another, few and far between, and the pursuit of photography as a hobby was a somewhat solitary one. Yet there were in those days followers of the art every whit as energetic as at the present time, if, indeed, taking circumstances into consideration, not more so, and, as a result, I could point to many instances of lasting friendships formed through the chance meeting of two perfect strangers, whose cameras proved the only means of introduction. Now, thanks to societies and conventions, one can scarcely set foot in a town of any dimensions within the limits of the three kingdoms without being able to hunt up at least one photographic friend to act as his guide, and, I am afraid it must be said, without also meeting with any number of volunteers in the same direction who are utterly unknown. In the old days it was usual to talk of the "freemasonry" of the camera, and to meet one in the course of our wanderings was equivalent to meeting a friend; but we get so much of that sort of thing at home now that we are apt to try and keep ourselves to ourselves as much as possible when abroad.

Yet it is curious that, under the old system of things, there was not anything like the same amount of freedom of intercourse between the members of the then existing societies that there is now. Of course, in every society there would be certain knots or coteries of friends who were probably such before they became connected with the society; but, as a rule, the meetings were formal affairs in which very little enthusiasm was evinced, and where a certain number of comparative strangers met once a month and tried

to be polite to each other without perhaps even knowing one another's names. So much was this the case, that even in London men whose names were "household words" in the photographic world were in the habit of meeting, and had done so for years, once or perhaps twice a month, without knowing any more of one another than they would have done had they lived in opposite corners of the kingdom.

But all this was quickly, if not suddenly, changed on the introduction of the "social" style of meeting. The first symptom of this change was perhaps shown in the "technical" meetings of the old South London Society, to attend which once a year photographers travelled from all parts of the country. True there was also the attraction of the Exhibition in Pall Mall, which was also open when the South London threw open its doors to visitors; but I know many provincials who would not have troubled to come for the Exhibition alone, and who don't come now, with the additional attraction of the Salon thrown in. Then, again, look back at the old "lantern nights" of the same society; what crowded houses they produced! And these gatherings, be it said, were not made up merely of the members, and their friends, and "their sisters, and their cousins, and their aunts," as was originally intended, although, of course, there was a good sprinkling of these. In addition, you would find there pretty nearly every recognised photographer in the neighbourhood of London, amateur as well as professional, "South London" as well as "Parent" Society, and I have even known the exclusive Amateur Field Club hurry over its day's outing and dinner in order not to miss the "lantern show."

I don't think it can be maintained with fairness, as has been attempted, that it was owing to the introduction of gelatine that the great alteration in society matters took place. It is true the two events were in some degree coincident, but I do not think gelatine was the cause, for the change would have occurred without it. It was a feeling on the part of photographers generally that a system of less formal intercourse was desirable, else why the invariable exodus from John Street or Pall Mall the moment the formal business was ended, and the subsequent gathering at Gatti's? It was said in fact, and I dare say with truth, that some members only turned up at Gatti's because they picked up quite as much of the evening's business there as they would have done at the more formal gathering, besides a lot more that was not on the agenda paper. Why, too, do the numerous meetings in London alone continue at least as well attended and keep as late hours now that gelatine, as a subject of discussion outside the plate factories, is as dead as the proverbial "doornail?"

At any rate the Brittlebank experiment soon showed that the promoters of the movement were on the right tack, and I shall not soon forget the scene at Gatti's on the occasion of the first public meeting called there to see how the public would respond. It had been expected that a private room would be available, but at the last moment this failed, being required for a public dinner, and when the "crowd" began to arrive in answer to the announcement in the journals, and all made for the usual corner, great was the excitement amongst the waiters and ordinary customers. The former were loud in their cries of "Plenty of seats this way, gentlemen," but the gentlemen preferred to stop where they were even if they had to stand, and "Tony"—Giuseppe was his real name, but he had been christened "Tony" for "shortness"—must have made a small fortune that evening. Eventually there was an adjournment to an adjacent street to the chambers of one of the members of both the existing societies, and I venture to think he never entertained so large a party before or since. Then the Photographic Club was formed, and the London and Provincial, and now it would be difficult to find a quarter of London that has not two or three meetings a week devoted to photography, with the "social element" not forgotten.

Although I have digressed thus far, and laid so much stress on the popularity of the more social style of gathering. I should myself be the last to attempt to put down the more formal meetings which serve to keep up the dignity of photography. It would be in the last degree pitiable to find ourselves without any meetings at all that still adhered to the ordinary formalities of scientific societies. But there is in the interests of ordinary photographers, who only meet for the purpose of comparing notes, no necessity to overdo the formality. In the case of the parent society—the Royal—which I think may be said to occupy a unique position and to represent the scientific phase of photography, it would be wrong to depart in any way from the rules as they at present exist; indeed, I am strongly of the opinion, although others I am aware are not, that it is only by keeping strictly to certain formal rules, and maintaining a certain dignity that has been dubbed "stuck-uppishness," that the parent society is now able to call itself the "Royal."

I notice that a motion is on foot to bring about an alteration in the rules, that will have the effect of annually introducing new blood into the Council and management; but surely the present provisions in that direction are sufficient. If it is intended, by the new movement, to dislodge, if not at once, gradually, those members of Council who, by the very length of their years of service, lend dignity to the Council, I for one think it a mistake. Going back as far as the early "seventies," there might have been some reason in such a movement; in fact, a precisely similar attempt led to a complete revolution in the Society, and the breaking up of what, at that time, was little better than the "clique" it was declared to be. But things have very materially altered since then, and, so far as I can judge, from outside, do not require any special attention at the present juncture.

There is one point, however, on which I would join in with the present agitators, namely, in only having on the Council such as are actually practical photographers, whether they be scientific, professional, or amateur. I have not by me, at the moment, a list of the present Council, and, if I had, it would be invidious to single out any instances for reference, if such there now be. But in days gone by, and that not far, the Council of the Photographic Society has been made up of names, eminent enough in their right place, but altogether out of that place in connexion with photography. The Royal Academicians would not elect the Archbishop of Canterbury R.A. because he whiled away his spare moments in sketching, nor would the Chemical Society elect as president an eminent mathematician who dabbled in elementary chemistry. Why, then, should the Photographic Society do differently? I had the accidental honour of sitting next to a very great man in the scientific world, at a lecture before the Society of Arts on a photographic subject. The individual in question had been, or then was, a member of the Council of the parent Society, but I found from his conversation that he was quite ignorant of photography, and although he used it in his researches, it was entirely by deputy.

Soon after the reform movement had been successful in 1873 or 1874, in which, by the way, not many living men are aware how important a part our lamented friend, Traill Taylor, took, it was suggested by one of the members that the Society should go in for a charter of incorporation. The proposal was met at the time with a shower of ridicule, and possibly the objections at that time were valid ones. But now, after twenty years, the change has been successfully effected, and, with altered conditions in every way, the Society seems in a fair way to reach and maintain a position it could not hope to aspire to at that period.

DOGBERRY.

"HOME-SENSITISED" ALBUMENISED PAPER, AND HOW TO USE IT.

BEFORE repeating some details of my practice I desire to make a protest on a personal matter. I think every one who has any personal knowledge of me will bear witness to my readiness to impart information, or give instruction to any one—amateur or professional—at all reasonable times; but, when I have treated any topic in an article over my signature in these pages, I consider that the proper method to adopt, by any one wishing for further information from me, is to apply for it through the Editor. If this unwritten law of courtesy were only occasionally infringed, I should not complain; but I have been so often appealed to by unknown correspondents from all quarters of the globe (not long ago a request for additional information came from Australia), that I wish here to place on record

my desire (which I think the Editor will endorse), that if any further information of my practice on any subject I write upon in these pages should be wished, I will willingly give it, but only through the medium of THE BRITISH JOURNAL OF PHOTOGRAPHY, and not through post. Three letters within the past month have been received by me from perfect strangers, asking for my advice. I sympathised with the writer of one, and replied by sending him three closely written pages; but, to prevent him trespassing further, I said, if he wished more instruction, I should require a fee. That effectually stopped him; he never even acknowledged the receipt of the letter of instruction I did send! but, as that is a common experience with me in these affairs, I do not think much of such an exhibition of lack of courtesy. The old results of practice I am about to pen are in reply to a letter I received quite lately. I replied to it that I had been compelled to make a rule not to give instruction through post to perfect strangers, but that the Editor might possibly insert an article from me on the subject indicated by the title of this paper, which was the matter inquired about.

The continually growing use of both gelatine and collodion sensitised papers bids fair to soon make all albumenised paper practice matters of ancient history; but, as there are evidently many who, like myself, have not abandoned its use, my remarks will not be without point to a number of readers. I am not acquainted with many photographers of this country who follow the practice common in America of fuming their paper before printing; but, for those who do, an immense gain in keeping property will be found if the paper after sensitising is floated on two successive baths of distilled water, so as to remove all the free silver. The paper will keep white for weeks, and need only be fumed immediately before use. It should be far more strongly fumed than would be right for the ordinary unwashed paper; indeed, it cannot be too strongly fumed, and it should be put into the frames at once. It will be found to tone readily, and to a good colour. Many years ago I worked this process to a considerable extent, and with very satisfactory results, but I found in practice that, as soon as the ammonia was dissipated, or nearly so, the paper printed slowly and unsatisfactorily. Besides fuming the paper, I also fumed the felt pads of the frame, and, after placing them over the paper in the frames, covered them with waxed paper. Prints so produced had a richness and vigour superior, I think, to those by any other method. I used to place the strong ammonia in a saucer, covered with wire gauze, at the bottom of a large stoneware jar, and then kept all the pads not required at the time in the jar ready for instant use. Eventually, however, I found that to get perfect results so much personal supervision was required; and, further, the ammonia at times made itself so uncomfortably prominent that eventually I entirely gave up the plan.

But, concurrently with the abandonment of the ammonia method, I adopted another mode of preserving to some extent the whiteness of the paper, which, down to the present day, I have consistently employed. I refer to the carbonate of soda pads, and this I expect it is that my correspondent makes inquiries about. It is very simple; there is no secret in it. Others besides myself have described it in these pages, but it is good enough to deserve repetition. The sensitised paper, as soon as dry, is placed between sheets of the prepared paper—alternate sheets of the sensitised paper and the carbonated paper. Thus stored, especially if under pressure, the paper will be whiter at the end of a week than after one day's keeping under ordinary conditions.

Then, again—and this is the most important item of practice—all the printing frames should be supplied with soda pads, to be placed immediately over the back of the sensitised paper during printing. A print needing three days' exposure during a spell of dull weather will be free from yellowness, and will tone quite easily when placed in the toning bath, a condition of things entirely out of question under ordinary conditions. I have heard it stated that these soda pads are apt to injure the negatives if left in contact with them, causing little pits to form in the varnish. I have not experienced this effect in my own practice, but it can easily be provided against by keeping in the printing frame, together with the pads, a second plain glazed-paper pad; then, when the frame was empty of prints and waiting for refilling, the pads could be so placed that the plain piece was in contact with the negative.

I have not yet described how the soda pads are made, and I will conclude my remarks by the necessary description. They are simply sheets of porous paper containing carbonate of soda within their texture. To make them, a strong solution of common washing soda is made, strength not material, say, twenty per cent. Thick blotting-paper is soaked with this, and allowed to dry. It is then ready for use. In practice it will be found very difficult to handle the wet paper, but, if it is stacked in alternate sheets of wet and dry paper, enough solution will be present to soak every piece, and it will not be so "rotten" to handle.

The method here described is in constant use in my printing room, and has many advantages, and, as far as I know, no disadvantages.

G. WATMOUGH WEBSTER, F.C.S., F.R.P.S.

SOLUBILITY OF SILVER IN HYPOSULPHITE OF SODA.

THE following question has been frequently asked by different people at different times, "Does a gelatino-bromide plate after development lose density during fixation?" and, up to the present, no completely satisfactory reply has been given.

According to Mr. Charters White, M.R.C.S., he failed to detect any difference between two portions of a dense film, one part soaked in a saturated solution of "hypo" for six weeks, and the other soaked in plain water. In each case the film was mounted in amieroscopical cell and examined under a microscope.

In a second experiment, made by the same gentleman, 162 grains of metallic silver were soaked in a saturated solution of hypo for one month. At the end of this time, after being washed and dried, it was found to have lost two grains. From these observations Mr. T. C. White concludes that metallic silver is insoluble in hyposulphite of soda, and that the density of a negative cannot be altered, however long it may be left in the fixing bath. (THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC, 1893, page 552.)

In THE BRITISH JOURNAL OF PHOTOGRAPHY for 1892, a correspondent (Mr. Albert Levy) contends that the developed silver image suffers reduction more or less during fixation, and practically attributes to hypo the property of dissolving metallic silver.

In a paper written by A. H. Sexton, F.C.S., F.I.C., in *Photographic Scraps*, November, 1894, we find the following statements:—"Some pure silver in a fine state of division was prepared, weighed, and portions were placed in solutions of sodium hyposulphite of varying strength, and left at the ordinary atmospheric temperature for some days. In every case a considerable quantity of silver was found in solution, so that finely divided silver is not insoluble in sodium hyposulphite. "Strips of gelatino-bromide prints, developed with hydroquinone, were put in large test tubes, covered with the solutions (hyposulphite of soda, 10 per cent., 20 per cent., and 10 per cent., with metabisulphite added to give acid reaction), and were left at the ordinary temperature, exposed to light and air. The action was slow, the image showed signs of fading in about four hours, and in about thirty hours it had almost completely disappeared. Having used amidol largely for bromide work, a large number of experiments were made with bromide prints developed with this. In one hour the image was very decidedly paler, in two hours it had become very pale, and in about four hours the image had disappeared. The reduction brought about by the action of hypo cannot be used for the reduction of over-printed prints, because the fine detail just disappears and the image soon acquires an unpleasant brownish colour, and even after very long action a very faint brownish image remains on the paper."

With such contradictory statements before us on such a subject, which, at first sight, seems so easy to decide once for all, we have, for some time past, been making experiments, in the hope of finding out the reasons for these discrepancies.

At the very outset it occurred to us that direct experiments on films of gelatine containing silver and silver bromide would not be suitable substances to deal with, as the matter might be very much complicated by the presence of the gelatine, and, in order to test the solubility or otherwise of silver in hypo in presence of silver bromide, we made the following experiment:—

Some silver bromide was prepared by precipitating some carefully

purified silver nitrate with potassium bromide; this was thoroughly washed with hot water in order to remove all soluble salts, dried, and preserved in a stoppered bottle in the dark. About five grammes of the silver bromide were exposed in a thin layer to daylight for ten minutes, and then treated with a ten per cent. solution of pyrogallic acid, and an equal quantity of a ten per cent. solution of caustic soda; the action was allowed to continue for fifteen minutes, when the liquid was poured off, and a second quantity, equal to the first in volume and of the same composition, was allowed to act for the same length of time, and then poured away. The mixture of reduced silver and unreduced bromide of silver, being washed with boiling water until all soluble matter had been extracted, was then ground in an agate mortar till it was reduced to an impalpable powder of uniform composition. A portion of this was placed between two watch glasses, and dried in a water oven until the weight became constant, showing that the powder had become quite dry. The weight of dry powder was found to be 1·7690 grammes. After being placed in a beaker, it was boiled with pure dilute nitric acid (free from chlorine), this was repeated four times, in order to be absolutely certain that all the metallic silver had been dissolved. After washing and drying, the residue, which consisted of bromide of silver, was found to weigh 1·5540 grammes. Subtracting this weight from the weight of mixture operated on, 0·2150 gramme is obtained, showing that the percentage composition of the original powder was:—

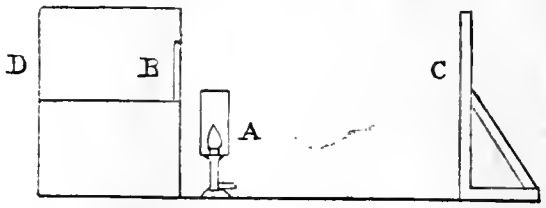
Metallic silver	12·15	per cent.
Silver bromide	87·85	„
	100·00	„

Another portion of the original mixture was dried in the same manner as before, and found to weigh 1·3700 grammes; it was then treated with 100 cc. of a twenty per cent. solution of hypo for ten minutes. This was poured off and replaced by another 100 cc. of the hypo, and allowed to act for a similar period, poured away, and the residue, consisting of metallic silver, washed, dried, and weighed. This was found to amount to 0·1646 gramme, and, calculating from this, the percentage composition, we obtain:—

Metallic silver	12·01	per cent.
Silver bromide	87·99	„
	100 00	„

The figures representing the amounts of silver present in the original mixture are almost identical, and well within the limits of experimental errors of a single analysis, and show that under ordinary conditions of the fixation of plates, *i.e.*, fifteen minutes' immersion in a twenty per cent. solution of hypo, no metallic silver is dissolved, and there can be therefore no alteration in the density of the silver image from this cause, unless the presence of the gelatine should alter the character of the silver deposit. In order to test this point, the next experiment we made was on an ordinary gelatino-bromide plate. The plate, after removal from the box in the dark room, was exposed for a couple of seconds to an ordinary gas flame, at a distance of about three feet. It was then developed in metol, carbonate of soda and sulphite. This developer was selected so as to avoid yellow stain in the finished plate. The development was not carried very far, as rather a thin image was required for examination. It was then washed and fixed in the ordinary way. The fixation was a little longer than usual (twenty minutes), so as to make sure that all silver salts that could be dissolved by the hypo were removed; the plate was then thoroughly washed and dried. On examination by transmitted light, the opacity of the plate at the centre, at least, seemed pretty uniform. The plate was then cut in two down the centre, and examined photometrically. The photometer first tried was of the Bunsen type, but we very soon found that it was difficult to recover the same readings, in consequence of the small amount of light transmitted. We then extemporised a photometer on the plan originally used by Mons. Bouquer, for the study of the absorption of light by different transparent media.

The apparatus is very simple in construction, and, as it might prove useful to others desirous of studying the absorption of light under different circumstances, we will endeavour to describe it. A box, D, about two feet long and one foot broad was taken, the depth is of no importance. In the bottom of the box two holes were bored, about three inches apart. This was raised by means of blocks till it was of such a height that a Welsbach lamp, A, could be conveniently placed between the two holes, but out of sight of the observer when looking through the holes, the lid side of the box being towards the observer. A large sheet of white paper, C, was divided into two, and each piece supported on a frame, one half opposite each hole, at a distance of two feet from the bottom of the box. On looking through the holes, one eye for each hole, it was easy to see whether the two pieces of paper received equal amounts of light from the burner; if not, the white screen which appeared the darker was made to approach the burner. With a little practice it was easy to hit off the exact positions when they appeared equally bright, and we could



Section of Bouquer's Photometer.—A, Welsbach lamp. B, plates being tested. C, reflectors (sheets of paper). D, position of observer's eyes.

thus ascertain what kind of error was likely to occur in any measurement. The paper being in both cases of the same kind, and there being but one source of light to deal with, for equal illumination the two pieces of paper ought naturally to be the same distance from the lamp. This photometer is far more simple than the Bunsen, as with the latter two sources of the same intensity are required, and this is not a very easy matter to realise, especially when it is necessary that they should continue to give out equal amounts of light over a long period. With Bouquer's photometer one source of light only being required, if it vary for the one screen, it varies for the other in the same proportion.

The photometer being set up, one portion of the plate was placed in front of one of the openings and the other in front of the other, B, and one of the screens moved backwards and forwards till they, or those portions that were visible, appeared equally bright. This was repeated several times and proved that the superficial examination of the plate was correct, *i.e.*, that the opacity was uniform. One of the pieces was then soaked for twenty minutes in a twenty-five per cent. solution of hypo. At the end of that time it was placed in water, to remove the hypo; and, in order to prevent any unequal change due to this second soaking, the other half was soaked in the same vessel. After washing for half an hour, the plates were allowed to dry spontaneously, and again examined. No change in opacity could be noticed, so that during twenty minutes' soaking in a twenty-five per cent. solution of hypo no change in density can be detected photometrically.

The same piece of the plate that had been soaked in hypo for twenty minutes was returned to the solution, together with a piece of gelatino-bromide paper which had been exposed so as to obtain a graduated strip, developed and fixed, and the two left in the solution for twenty-one hours. During this interval the paper, for some reason, shifted in position and covered a portion of the plate. When examined at the end of this time, it was found that the portion of the plate which was uncovered by the paper had changed from black to brownish yellow, while the covered portion was still black, but much less dense. The paper had lost its original blackness and was also changed to yellow, the different gradations being still distinctly visible. The portion of the plate left in the hypo for twenty-one hours was again compared by means of the photometer and, though the colours were very different, yet it was easy to determine their relative light-stopping properties. The fixed portion was to the original in the ratio of 1:11. The same pieces were then used to print a piece of gelatino-bromide paper, in order that we might estimate their relative powers of stopping the actinic or active portion of gaslight. In order to compare the two, the strip of paper was again exposed, so as to produce a scale of gradation, as was

done previously, exposing for sixteen, eight, four, two, and one seconds to a gas flame two feet off. On development, it was found that the tint which was produced by one second of the plate long soaked in hypo corresponded to the tint produced in six seconds on the original portion of the plate, thus showing that its value as a printer was reduced from six to one.

A. HADDON,
F. B. GRUNDY.

(To be continued.)

WHAT IS IMPRESSIONISM?

IN the course of a review of Mr. R. A. M. Stevenson's *Art of Velasquez*, a writer in the *Spectator* gives the following definition of impressionism:—

"Once the impressionist theory of vision and painting is grasped, it is easy out of various writers, even out of Ruskin himself, to collect passages skirting it or glancing at it. It is the doctrine that Reynolds attempted to state. It is what painter after painter has more or less consciously applied without being in words able to express it clearly. Mr. Stevenson is the first to make a good book about it.

"The name has been much against the thing with those to whom it was only a word. 'Impressionism' is a luckless enough term for a revolution in pictorial vision as radical as the introduction of chiaroscuro, of linear, or of aerial perspective. Inevitably it has been taken to mean hurried sketching. Now, a pre-Raphaelite may sketch hurriedly, but his sketch is not impressionistic, it is merely a hasty statement of his ordinary habit of vision. That habit is one of simple addition. If he has plenty of time, he puts down 1, 2, 3, 4, 5, 6, 7. If he has less than half the time, he puts down 1, 2, and a bit of 3. This impressionist goes to work by summing these particulars before he puts down the result. He is therefore capable of a more rapid statement, but time is not of the essence of his procedure. His process of thought may take a longer time than the other's thoughtless enumeration. Nor, again, is a pre-Raphaelite picture made into an impressionist by blurring it over, as some have fondly imagined. (Painters will tell you that they do 'impressionist' work *sometimes*.)

"Impressionism, then, does not mean hasty impression nor misty impression. It means *unity and order of impression gained by focussing the subject*. Just as linear perspective introduced a unifying natural action of the eye into painting, with one angle of view in place of a dozen, so does impressionism follow the natural eye, with one focus for a dozen.

"Focus affects the clearness of definition in two ways. If a number of objects, A, B, C, D, E, stand at different distances from the eye, and the eye rests upon and adjusts itself to C, the nearer objects, A and B, and the farther objects, D and E, are thrown out of focus and are blurred. This may be called the *focus of distance*, and to represent two objects at different depths in a picture with the same clearness of definition is to puzzle and contradict the eye.

"But there is also the *focus of attention*. According as the eye selects one feature of a scene, or allows itself to wander more freely, the definition of the parts will alter; and, if we wish in a picture that it should be known what we were looking at, a not unreasonable desire, we must follow this procedure of the eye. If I look at A and B together, my attention is more diluted than when I look at one of them, and the definition of each is weaker—it is the pattern including the two that is defined. If I look at A directly, with B still there, but not attended to, the definition of B is fainter. The pre-Raphaelites call attending to everything equally being 'faithful.' It is a stupid and self-defeating faithfulness that is false to all that gives vision significance.

"So much for form. A similar law holds with regard to colour. The impressionist will not skin off all distance till his eye reaches a flayed local colour. He will fix with himself a distance that relates all local colours in a key. Nor will he scrutinise each patch of colour in turn with equal attention. If a yellow spot is focussed in a scene, all the other colours alter; if the eye leaves the yellow to play more freely, the yellow loses its insistence, and the *colour of the scene* asserts itself.

"It is only the unthinking who will accuse impressionism, thus understood, of being an easy slap-dash kind of painting. To appreciate the exactly right force of definition for the parts in relation to the whole is a task that employs the rarest faculties of vision, since to a sensitive eye a single false accent will destroy a whole picture. It is the pre-Raphaelite elaboration of all parts with equal force that is the easy plan. The very brute camera is not so stupid. And, if it be argued that all this is a matter of mechanical and realistic rendering of facts, the assertion is manifestly untrue. Attention is governed by feeling, every change in the definition of an object means a change in our emotion about it. Impressionism, in a word, employs the means of emphasis natural to vision. Other methods of emphasis there are, that of the decorative line, the silhouetted shape, the colour patch, and a painter may bind himself by the simpler conventions if he pleases; but, if he does not comprehend impressionistic vision, he is not full-grown in the theory of his art, and is blind to its later history and triumphs."

A NEW LENS—THE PLATYSTIGMAT.

THE Platystigmat is the name of a new lens just introduced by Mr. W. Wray, of North Hill, Highgate, and which, on the occasion of a recent visit to his establishment, we had the opportunity of trying.

The distinctive name chosen for the lens is, we believe, intended to signalise its possession of a flat field associated with the absence of astigmatism. The lens may be described as a symmetrical doublet, each combination consisting of a cemented triple, in the construction of which the now well-known properties of certain of the Jena glasses have been availed of, but we are without precise details as to the curves of the component elements.

The Platystigmat of five inches focus gives a flat field over a very wide angle, ninety degrees approximately, and, although at full aperture, only intended to cover quarter-plate, it perfectly well covers a size larger plate without being stopped down. At *f*-16 it covers a half-plate and at *f*-32 a whole-plate, thus proving its powers as a narrow or wide-angle lens at will.

In the way of flatness of field, as we have pointed out, the lens is all that can be desired, and, employed with the apertures and for the sizes enumerated above, it is remarkably free from astigmatism; hence it possesses, and that in a marked degree, the very qualities which modern opticians have set themselves the task of imparting to their productions. We need therefore hardly remark, from the data given, that the Platystigmat is capable of being subjected to a variety of uses which constitute it a most serviceable all-round lens.

HEAT AND TONE.

By E. W. BLUNT.

[Written for the ALMANAC, but received too late.]

SOME little time back I had occasion to take a gelatino-chloride print off its mount, and for the purpose I resorted to steaming it. Although the result was not entirely successful in the direction originally aimed at, an unexpected effect was produced that was rather interesting—the tone of the print, which, before treatment, was a purple black, of a decidedly "cool" shade, was, under the influence of the heat, changed to a brown tint, verging between chocolate and sepia, and of a distinctly pleasing character. The paper was Ilford matt-surface, with which, although I am rather partial to warm tones, I am unable to get them with any degree of certainty in the ordinary mode of working; but, if this plan should be reliable, as upon one or two subsequent trials it seems to be, it is easy enough in practice. I may say that the process of steaming does not seem to have any injurious effect in loosening or dissolving the picture, on the matt paper at any rate, though possibly with the glossy surface it might be different.

The question may be raised is, Are the tones so produced permanent? So far as I can see, they are for the time being, that is to say, wetting and redrying the print produces no alteration.

But is the action of heat likely to set in motion any action that is calculated to go on and lead to the ultimate fading or destruction of the image? I am told that albumen prints, after fixing and washing, have their tones rendered considerably warmer by immersion in very hot water, and that the colour so produced is apparently permanent. This action seems analogous. Is it reliable?

GLASGOW AND WEST OF SCOTLAND AMATEUR PHOTOGRAPHIC ASSOCIATION.

ANNUAL EXHIBITION.

(From our own Correspondent.)

IN Glasgow and the West of Scotland the approach of Christmas is always looked forward to by a very large number of amateur and professional workers with interest, on account of the annual display of work in the Association's rooms, 180, West Regent-street, and this year has been no exception, for the extensive wall space is occupied by as fine a collection of amateur photographs as was perhaps ever displayed by one association.

In judging the exhibits the Council have this year made a fresh departure. In former years the awards were made either by ballot of the members or by professional Judges. This year Messrs. Alexander Robb, Ralph Elder, and Thomas Taylor, who were assisted by two local professionals, undertook the onerous duty of judging the pictures, and but slight exception—if, indeed, any—can be found with their decision.

A visit to the elaborately furnished rooms of this Association is at all times a pleasant undertaking to any one interested in photography, were it merely to inspect the operating, enlarging, dark rooms, and library of the Association, each of which is fitted up in a most lavish manner, and which is perhaps equalled by no other association in the kingdom.

The Exhibition this year, so far as the excellence of the work is concerned, is a very long way in advance of past years; in fact, not a single poor photograph finds a place on the walls.

Mr. Goodwin has succeeded in gaining first honours for both lantern slides and stereoscopic transparencies. In the former there were no less than twenty-three competitors, and the Judges were aided in deciding this class by the services of Mr. Arch. Watson, who along with Mr. Steventon, were present when the slides were judged upon the screen.

Annexed is list of awards:—Landscapes (over half-plate), silver medal, Stewart Smith; bronze medal, John Ferguson. Landscapes (half-plate and under), silver medal, J. C. Oliver; bronze medal, J. M. Ewing. Enlargements of Portraits, Groups, and Figure Studies, silver medal, Professor Finlay, M.D.; bronze medal, J. C. Oliver. Enlargements of other subjects, silver medal, Professor Finlay, M.D.; bronze medal, Archibald Watson. Pictures taken at Outdoor Meetings, silver medal, J. C. Oliver; bronze medal, Archibald Watson. Portraiture, silver medal, John W. Eadie; bronze medal, Stewart Smith. Hand Camera, silver medal, A. Lindsay Miller; bronze medal, J. Imbrie Fraser. Instantaneous, silver medal, John W. Eadie; bronze medal, A. H. Duncan. Lantern Slides, silver medal, Wm. Goodwin; bronze medal, Thos. W. Robertson. Stereoscopic, silver medal, Wm. Goodwin; bronze medal, Wm. Goodwin; extra bronze medal, John W. Miller.

TASTE IN PHOTOGRAPHY.

What is Taste?

On referring to the dictionary, you will find, under the heading "taste," various significations of this much-used word of the English language; but the one for our purpose will be the following: "In æsthetics, the faculty of discerning with emotions of pleasure, beauty, grace, congruity, proportion, symmetry, order, or whatever constitutes excellence, particularly in the fine arts and literature." This agrees well with Alison, the standard authority on matters of taste, who says: "Taste is, in general, considered as that faculty of the human mind by which we perceive and enjoy whatever is beautiful or sublime in the works of nature or art." Some later authorities enlarge upon these definitions, and consider taste to consist not only in the perception and enjoyment of beauty, but also in the recognition of a moral quality. Of this number are Carlyle and Ruskin. This moral quality we may leave aside, and consider taste only in relation to the beautiful.

Although taste is thus defined, it is more easily discoverd in its results than expressed by any mere order of words. Most persons appear to have a natural gift, and show some emotion on beholding a beautiful object either of form or colour, and, as Dr. Blair remarks, "they sometimes strike in the same manner the philosopher and the peasant, the boy and the man." In general, a bad work of art is speedily passed over, and the fullest attention given to that which is better, even by those who have had no art education. Yet these rough connoisseurs may be quite unable to give any clear reasons for their choice, or to say upon what principles they preferred the one work before the other. Of course exceptions can be found, but such do not destroy the rule, but rather show the variety and complexity of tastes. Many such act out of the spirit of contradiction. Every photographer can recall to mind the sitter who invariably chooses a bad proof before one that, in the general opinion, is decidedly superior. The same spirit is often found in experts, and Hazlitt sums up such men as follows: "If there are connoisseurs who spend their lives and waste their breath in extolling sublime passages in obscure writers, and lovers who choose their mistresses for their ugly faces, this is not taste, but affectation."

Dismissing, therefore, these exceptions, it may be stated that all persons are possessed of taste; they have a natural faculty of preferring some things before others merely because they consider them more beautiful. This power naturally varies with each individual. "In some men only the feeble glimmerings of taste appear, the beauties which they relish are of the coarsest kind, and of these they have but a weak and confused impression, while in others taste rises to an acute discernment and a lively enjoyment of the most refined beauties."—Blair. Taste is thus really a feeling, a sentiment, an emotion rather than a judgment upon things. As Ruskin says, "When we analyse it, it means, of course, merely the right direction of feeling."

Like all feeling, taste, when once it obtains expression, is capable of acting upon the feelings of others. Thus, the artist or photographer who can fix the sentiment of taste upon his material will from thence be able to influence and cause similar sentiments in all those who behold his works. Although of such a vague and apparently unsubstantial nature, it is taste which will finally decide what a man's work will be; and it is only through his work that we can judge of the correctness or badness of an artist's taste. Taste, then, is just that quality in a work of art which gives it either success or failure.

Taste in Business.

My readers may be asking what all this tall talking has to do with them as portrait or landscape photographers, and I can only answer, Much more than the average photographer appears to think. I also believe this question of taste has a most important relation to the business of a photographer, even in its most commercial aspects. If we look around and pick out the men who have made the most rapid progress, and raised themselves to high positions in the profession, we shall be compelled to admit that the one distinguishing characteristic of their work is—taste. From a technical point of view, their work may be not the least better, and sometimes worse, than the men who are struggling around them. Yet, in spite of this, such men seem always to be prospering, and have no difficulty in obtaining sitters. Their superior taste saves them, whilst the man doing work of equal quality, and yet lacking in a sense of taste, is lost. It is useless to lower his price, for his rival can still command customers enough to pay well for the superior article.

It is often a mystery to some photographers how it is a rival succeeds where they fail. On comparison, they cannot see that his work is superior to their own. I attribute this to nothing else than the lack in the unsuccessful photographer of this saving grace of taste. Having little himself, he fails to grasp the essential quality of his rival's work. It is just this want of discernment which makes the difference. Taste, then, has a business utility.

In this connexion it must not be forgotten that the general art education of the people has made rapid advances of late years, and that the old-fashioned painters' and photographers' ideas of the curtain and the pedestal as necessary accessories are long out of date. If, therefore, a photographer's taste has failed to keep up and improve with the changed conditions, it is certain that he must be left behind with his curtain and pedestal. To succeed, a photographer must not only keep up with the general taste of the times, but must also advance, and, if possible, lead the taste of his customers. That such an advance in photographic taste has taken place in the past can be readily verified by comparing the average portrait of to-day and those that have survived from past years. Some of the best of to-day, more especially amateur productions, have reached a high state of excellence, and exhibit the most refined taste. Some may deny this excellence of amateur productions, but I maintain that the amateur, in this, as in many other respects, has been the leader of the professional photographer. If there is one thing above another which marks the amateur from the professional, it is the taste of the former. If once the amateur gains a complete mastery of the technique of photography, he generally produces some fine artistic work. This arises from two causes: Firstly, the spirit with which the amateur works—for pure love of the art causes him to give his emotions the fullest play, and they come out more distinctly in the work he produces; secondly, the amateur, as a rule, is a man of education, and more cultured than the photographer. Now, culture is simply the development of natural taste, and thus it comes out in his pictures.

Can Taste be Acquired?

Taste must be largely a natural gift rather than acquired, yet, at the same time, a natural gift is useless without training and exercise. A fine taste can only be formed and strengthened by reflection, study, and comparison. The two principal marks of a fine taste are delicacy and correctness, and these are naturally of a slow growth. "An eye for the beauties of painting is never all at once acquired. It is gradually formed by being conversant among pictures, and studying the works of the best masters."—Blair.

Study of the works of the masters of an art is always a fruitful source of improvement, for by this method we can make a comparison of lower and higher degrees of the same beauty. But it is no gain if, by this study, we are led to imitate these masters, for nothing allows of so much diversity and variety as matters of taste. It is therefore well to strike out a path of our own rather than follow other men. Exercise is likewise most helpful, by constantly trying, experimenting, and endeavouring to express his taste in works, the photographer will greatly increase the facility of acquiring tasty pictures. The alteration of a single fold of a dress, or the line of a chair, or foliage, will often produce a marked improvement. These are the little things which show taste.

It also helps to develop taste to be surrounded with objects that are at once refined and beautiful. To the photographer this means combining the useful with the beautiful. "Even the necessary arts are exalted into dignity by the genius that can unite beauty with use," says Alison. This taste can be exercised and displayed by every photographer in the choice of furniture. An excellent plan, followed by many, is to purchase articles, whenever you see any adapted to your purpose, instead of selecting from a limited choice of entirely unsuitable things.

The sordid details of business must not, however, engross the whole attention, or that delicacy, which is the essence of taste, will be extinguished, as Alison remarks, "The finest natural taste is seldom found able to withstand that narrowness and insensibility of mind, which is perhaps necessarily acquired by the minute and uninteresting details of the mechanical arts."

Correctness, being also a quality of taste, is only to be acquired by comparison. Photographers, at the present time, have a tendency towards the ill-defined, and Ruskin asserts that the ill-defined constitutes bad taste. In opposition to this the black and white artist leans towards the photographic and well-defined. It is interesting to compare the illustrated journals of to-day with those of ten years ago, and to notice how largely the modern artist is dominated by the photographic spirit. Some of these drawings are so photographic that it is difficult to distinguish them from products of the camera. In this case we have a marked advance in taste that is worthy of study. Many other instances might be given showing how taste may be acquired and used, but these suggestions must suffice, they can be expanded by any who care to think over the subject.

It must not be forgotten that the foregoing remarks apply to every photographic worker from operator to printer, and even spotter and mounter; taste can be displayed in all branches of photographic work; it is in fact a necessity. Photography is a profession because it cannot be acquired by rule and measure. It is very difficult to examine for proficiency in photography; you may examine in chemistry, optics, mathematics, but the test of a photographer as of an artist is the taste and ability displayed in his works. Taste, therefore, is the first and last requisite in a photographer.

JOHN A. RANDALL.

DOINGS AT THE CAMERA CLUB.

THE past year has been a somewhat anxious one for the executive of the Camera Club, unforseen difficulties having presented themselves; but the closing months of 1895 have brought with them beneficial changes, and with those changes have come renewed hopes for the future of the institution, and it is believed that under the sway of a new Manager, in the person of Mr. Seyton Scott, the Camera Club will now enter upon a period of greatly increased prosperity. Already this is foreshadowed to some extent by the number of applications for membership which have come to hand during the month—a result largely due to increased vigilance upon the part of the executive, as witnessed by the bill of fare provided for the entertainment and instruction of the members and their friends.

A cynic once observed that the attitude of the public towards those whose business it is to speak to them from a rostrum is expressed by the aphorism, "Entertain me, if you can; instruct me, if you dare." That there is much truth in this remark is instanced by the balderdash which the public will flock to hear, while real merit is unappreciated and passed by. Even in a coterie like the Camera Club the rule holds good, but in a much minor degree, for the bulk of the members are earnest men, who would not readily lose the opportunity of benefiting by the experiences of others who are working in the same direction as themselves; but there are others who are so far human that they very much like being amused, and the smoking concerts are most heartily enjoyed by them; and let it be noted that as a rule—of course, there must be exceptions in such a matter—the music is of the best, and the recitations and other forms of entertainment quite above the average. One smoking concert per month, which is the rule at the Camera Club, is not too much by way of relaxation from more solid mental food, and the patronage which they meet with is a plea for their continuance.

The month of December has been decidedly photographic in tone. The elementary series of lectures has been kept going, first by Dr. C. S. Paterson, who on the 9th ult. discoursed on enlarging photographs by means of artificial light, and by Mr. E. Calland, who a week later gave the members his experiences with carbon printing, while at the same time a retouching class, under the direction of Mr. Redmond Barrett, has been formed for the benefit of those members who have not yet arrived at that stage of "forardness" when "retouching" becomes a crime. We regret that accident prevented us hearing Mr. Pringle's account of his "Journey to the Dolomites and Back," for we are sure that both matter and pictures would be worthy of their author.

Mr. Henry Blackburn's discourse on *The Value of a Line* drew a big audience, for this gentleman is fully acquainted with the art of blending amusement with instruction, and, moreover, he knows his subject well. Those who do not know what Mr. Blackburn has done for illustrated journalism generally, or who forget that he is the creator of the illustrated catalogue at picture galleries, might perhaps be puzzled at the title he chose for his lecture, *The Value of a Line*, for there are so many kinds of lines. There is the *cheap* "line" at the linen-draper's, warranted "fast" as to colour. There is the antithesis to this, as exampled by the L.C. & D. Railway line. There is the clothes line, and the poetic line, &c. Mr. Blackburn's line is that mysterious thing which a pen charged with india ink will inscribe upon a piece of cardboard, the disposition and direction of which will determine the question whether a man is an artist or a duffer. Mr. Blackburn has had, perhaps, more opportunities of judging of the value of these ink lines than anybody else, for he is the compiler and originator of *Academy Notes*, those pleasing little handbooks which are illustrated by pen-and-ink sketches of the exhibited pictures by the artists themselves. The lecture was a pleasant one, given without farther reference to notes than was afforded by the pictures thrown on the screen, pictures mostly of pen-and-ink drawings by various artists more or less known to fame. The value of the electric lantern as a demonstrator was never better exemplified, the drawings standing out upon the screen with every touch of the artist's pen distinctly and beautifully rendered. Mr. Blackburn gave a pleasant little homily about each picture as it was shown, and was sparing neither in praise nor blame when deserved. A drawing by Mr. Pennell came in for both. It was a picture of the Market Hall at Yarmouth, in which the big black sail of a barge in the middle distance came in for much severe criticism. The examples were not all of the simple line sort, some of them being due to those embossed papers prepared for process artists which come under the head of scratch boards; that is to say, the paper or card is faced with a chalky compound, upon which are printed raised lines, which can be scratched or cut away to give the lights of the picture. Some of the work produced by this method is very effective, but it will at once be seen that, easy as it may look, it requires perhaps more artistic ability than the more laborious ink line to do it justice.

The discussion on Mr. Blackburn's paper was amusing, if not very valuable. It would seem that, directly the subject of "art" in any form is started at the Camera Club, there is fun to be looked for. It is a curious characteristic of human nature that a congregation of sane men should enter upon the discussion of a subject upon which they know, as a foregone conclusion, they will never come to agreement. So it was upon this occasion. One or two artists took Mr. Blackburn to task for showing sketchy pictures, which could not give a fair idea of a man's capabilities, as examples of a man's work. But we think Mr. Blackburn was quite justified in putting the sketches forward, as he really did, just as one might show a letter as a specimen of a friend's handwriting. Mr. George Davison gave Mr. Pennell's work a rubbing down, which it would have startled that genial artist to hear. Altogether the evening was a pleasant one, and Mr. Blackburn's half promise to lecture again at an early date was received with enthusiasm.

On December 5 Captain J. Thomson, one of Her Majesty's Inspectors of Explosives, entertained and instructed the Club with a lecture on the use and abuse of those compounds which have the unenviable reputation of dealing such widespread damage to men and things. Photographers as a rule—always excepting certain excitable members of the fraternity—are a peace-loving lot, and may therefore be supposed to regard explosives as somewhat outside their environment; and, if we were puzzled to find a reason for this lecture before a photographic body upon a subject foreign to them, we should search for it in the use of gun-cotton, and in the accidental manufacture of silver fulminate, which has occasionally arisen in experimental hands, even when sun pictures were the only results aimed at; but, in reality, no excuse need be found for the reading of an excellent paper upon a subject which interests all of us more or less, and which, moreover, was illustrated by several excellent photographs. The *Times*, in its notice of the lecture, says that it was illustrated by "dissolving views." This is very funny, and there is some excuse for this mistake, for actual explosives too often have been illustrated by "dissolving views," a well-known case in point being that of the two miscreants who hired a boat with the intention of blowing up London Bridge, and who were blown into such minute particles that not a visible fragment remained.

It was interesting to learn that, if any one wants to explode himself or any of his friends, there are about 1000 different mixtures from which he can choose the one best suited to his requirements. A quarter of a century ago there were not more than thirty, so that the modern operator has a far more extensive *répertoire*. The invention of gun-cotton, which did so much for the photographer of old, and is doing so much for him now in the manufacture of celluloid films, gave the great impetus to the science of explosives; and, although many are of the opinion that the world would be better without such terrible weapons, we must remember that industrial enterprise in mining, excavating, &c., has benefited enormously by the use of explosives. It is, indeed, difficult to imagine how the world could get on without them. With regard to their abuse, Captain Thomson had many interesting and well-executed photographs to show. These were chiefly views of places partly wrecked by dynamite bombs, taken under the auspices of the Home Office—an uncanny

memento of the reign of terror which we passed through only a few years back. Of course, the lecturer had something to say about that much-discussed indiarubber-like compound known as cordite; and it is a comfort to learn, after all the abuse which has been heaped upon this modern substitute for "villainous saltpetre," that it has been found to withstand extremes of temperature as well as the thunders of Chancery lawsuits, and that, on the whole, it is really a reliable article, without the terrible danger in case of accidental ignition which is inseparable from the older explosive. It seemed a pity that some contributor to the *P. M. Gazette*, which has its offices almost next door to the Camera Club, and which has so taken up the case of the alleged worthlessness of cordite, was not present to spar with Captain Thomson, for we should then have had some fun. But all was peace. No one was even blown up, physically or metaphorically, and the members of the Club rested in their beds that night just as if no means existed of landing them skyward.

Considering that it was so near Christmas, and considering also the abstruse nature of the subject, there was a fair attendance at the Club on the 19th, to hear Dr. Ackworth's discourse on the speed determination of plates. Perhaps it would be more correct to say that such a paper promised to be abstruse, for the matter was so clearly set forth by Dr. Ackworth that all difficulties of understanding it disappeared, and the time flew fast while he spoke, a sure sign that his audience were interested. It must be feared though that the great majority of workers care little about speed determination. They are content to buy the quickest plates which they can obtain, and leave the experimentalists to determine whether Jones beats Smith in the rapidity of his goods, or whether Robinson excels both. They will buy Robinson's if they hear that it has been definitely determined that Robinson's are the quickest plates in the market, but why they are the quickest, or by what method they are proved to be so, they care not one straw.

Dr. Ackworth commenced his paper by telling his hearers that this question of the determination of plate speeds was not a simple one, as some people might think. In reality it was a highly complex one, for so many factors had to be taken into consideration. This was shown by Captain Abney's paper some months ago, when he showed how much the temperature at the time of exposure influenced the results obtained. The primitive method of testing plate speeds was to expose two plates for the same period to the same light, develop and fix them with the same developer under the same conditions, and then to find out which plate showed the greater amount of deposit. He now showed two plates which had been thus treated, A and B, in which A was denser than B; but, by extending the time of exposure for both, it was seen that B became denser than A, and therefore this method gave contradictory results. It was clear, then, that we must not depend upon one exposure, but must submit each plate tried to several before we can obtain a just idea of its merits. We must remember, too, that a plate may have the capacity of giving great density although it may be comparatively slow in action; and here we have the reason for the apparent contradictory behaviour of the two plates just exhibited.

The lecturer then explained the action of Warnerke's sensitometer, and pointed out how it differed from Spurgs's instrument. He also threw on the screen the results of exposing different plates under Warnerke's apparatus, and showed that, although one plate might be much quicker than another, the gradations were quite different when compared with one another.

Next the two systems of speed determination due to Captain Abney and Messrs. Hurter & Driffield were submitted to comparison. In both the plates were exposed behind a rotating sector, so arranged that different parts received measured periods of exposure; but, while Captain Abney used an amyl-acetate lamp as his luminant, Messrs. Hurter & Driffield preferred a standard candle. In the lecturer's opinion, the Pentane Argand lamp was superior to either as a reliable standard to work from. Working with the rotating sector, the plate, after development, shows four gradations, and each is subsequently carefully measured by means of a photometer. It might be remarked that in Captain Abney's experiments the negative had been regarded as a means towards an end only, but Messrs. Hurter & Driffield have regarded the negative as *the* important thing. The lecturer proceeded to show what an important factor was represented by fog on a plate, and he proved, by a series of diagrams, the amount of light stopped by: 1, the glass; 2, gelatine and glass; 3, fogged gelatine, &c. He then dealt with the question of development, and said that the nature of the developer employed exercises a very great influence upon the results obtained in speed determination. And here came a very interesting illustration of this important point, in the form of a plate which had been cut in three parts, one part being developed with ferrous oxalate, another with pyro-soda, and the third with metol-soda. There was nothing to choose between the two latter—they were, for all practical purposes, alike; but the portion developed with ferrous oxalate lagged far behind so far as density was concerned. It would have been interesting to have known what plate this was, for it is certain that ferrous oxalate, with some, will give as great density as it is possible to obtain. Dr. Ackworth also called attention to the remarkable difference in the colour of the deposit, by which the actual density in its value for printing purposes was much increased in the two plates developed by pyro-soda and metol-soda. This difference is not generally recognised in speed measurements.

There now followed a series of most interesting lantern slides which had been prepared by Mr. Charters White. They were photo-micrographs, which had been obtained from different unexposed plates, in order to show the grain of the emulsion under a magnification of 100 diameters. This was increased to about 3000 diameters on the lantern screen, and the brilliant electric light brought out the details of the slides with great distinctness. As might have been expected, the slow plates showed the finer grain, the best in this respect being a chloro-bromide plate. We were sorry that a pure chloride plate was not shown, for this question of fineness of grain is a very important one. We were also shown the mischief wrought by fog without exposure, and this interesting series of photo-micrographs brought the paper to a close.

As to the discussion, there was none. Mr. Warnerke tried to draw Dr. Ackworth by stating that, although the lecturer had very clearly explained the different methods of speed determination adopted by Captain Abney and Messrs. Hurter & Driffield, he had not told his hearers which was the better of the two. Mr. Warnerke thought that they had a right to expect an enunciation on this important point. But Dr. Ackworth would not allow any salt to be put upon his tail. He answered, in a guarded manner, that it was difficult to say which was the better of the two. Much might be said for both systems. There were so many factors to be considered, that he really could not commit himself to a definite reply. The Rev. F. C. Lambert, then, in a few well-chosen words, closed the proceedings, at the same time expressing the opinion, which most others shared, that Dr. Ackworth's paper was one of the most valuable ever submitted to the consideration of the Camera Club.

Our Editorial Table.

The Beernaert Lantern Plates.

Mr. Oscar Scholzig, of Dashwood House, 9 New Broad-street, has sent us samples of the Beernaert Lantern Plates which are being introduced by the E. Beernaert Dry Plate Company. With each box of plates is given twelve magnesium wires for making exposures, in addition to twelve masks and binding strips. The plates are issued in two series. Series E 1 is a chloride print-out plate, and it is sufficient to expose it in contact with the negative from ten to fifteen minutes, in direct sunlight, to obtain a rich red-toned fully printed out image. The slide need not be fixed or washed, but can be used direct in the lantern, or exhibited as a transparency, provided, as it is pointed out, it is not exposed to a very strong light for a great length of time. Recently, an hour's exposure to daylight was insufficient to degrade one or two plates that we printed out in this manner. It is a quick and convenient way of making a lantern slide for a special purpose, and, when time allows, the image can be fixed and finished in the usual way without undergoing reduction.

The series F 1 plates are for making slides by exposure and development in the ordinary way, and a number of specimen slides, so made, have been submitted to us showing that a perfect command over the colour of the deposit is obtained, the range extending from cold black to warm red. The plates have evidently been well and carefully made, and should be very popular with photographers undertaking lantern-slide work.

With reference to the Beernaert plates, Mr. Scholzig informs us that not only are the different kinds and rapidities of Beernaert plates all one price, but they have adopted a system of calculating the prices, strictly on the basis of the surface coated, only taking into consideration the extra cost of the very thin glass used for the smaller sizes, and of the very thick glass necessary for the very large plates. The basis price is 10*s.* per square metre, or 100*s.* per dozen square yards. Thus the large-size plates come remarkably cheap in comparison with the general run of prices. The Beernaert Company have put up thirty new machines for the production of their plates, films and papers of all kinds, and they claim to possess the only factory in the world capable of evenly and cleanly coating plates of any size, up to the largest sheets of glass that can be manufactured.

The Practical Photographer for 1895.

Bradford: Percy Lund & Co.

The bound volume of our contemporary, for 1895, makes an attractive book. It is full of tastefully chosen illustrations in half-tone, and the literary portion, under the careful editorship of Mr. "Matthew Surface," embodies a great deal of excellent photographic teaching.

News and Notes.

A SUBSTITUTE FOR GOLD.—A French journal describes a new and promising substitute for gold. It is produced by alloying ninety-four parts of copper with six of antimony, the copper being first melted and the antimony afterwards added; to this a quantity of magnesium carbonate is added to increase its specific gravity. The alloy is capable of being drawn out, wrought, and soldered just as gold is, and is said to take and retain as fine a polish as gold. Its cost is a shilling a pound.

GELATINE is transformable into a kindred substance, gelatose, or protogelatose, characterised by want of the property of forming a jelly, and of being precipitated by a standard solution of sodium chloride. In cultures of liquefactive microbia it is observed in the first moments that the gelatine is changed into gelatose. Gelatine loses the property of jellifying if left in contact with an alkaline chloride or iodide. With the fluorides the transformation is only partial. The change may be named saline digestion.—A. DASTRE and N. FLORESCO.

APPARENTLY, although Christmas numbers have multiplied tenfold, their popularity is still as great. The Christmas number of the *Windsor Magazine* was actually "sold out" on the day of publication, despite the enormous edition that was printed. *Apropos* of this, it was computed that, if the copies of the magazine were placed end to end, they would cover a distance of forty-seven miles. The great demand for the *Windsor* is probably partly due to the fact that with each copy is given a complete volume by Conan Doyle, extra to the diversified contents, numbering 224 pages.

MESSRS. LONSDALE BROS., of 22, Goswell-road, Aldersgate-street, E.C., write: "We have great pleasure in informing you that we have taken commodious and centrally situated premises (containing upwards of 5000 square feet) at the above address, which we are fitting up with the most modern machinery for the manufacture of photographic apparatus and camera brass-work. The establishment of works in the metropolis has been induced by the increasing growth of our London and export trade, and we believe it will be for the greater convenience of the majority of our customers, many of whom have parcels contracts with and pay periodical visits to London, when they will have the opportunity of personally inspecting our manufactures in our new showrooms.

THE Durham City Camera Club's Fourth Exhibition of Photographs will be held in the Shakespeare Hall, North-road, Durham, on Tuesday and Wednesday, February 18 and 19, 1896. Prize list for exhibitors. The following classes are for open competition:—Class I. Landscape or Seascape, any size or process. Class II. Portraiture and Figure Study, any size or process. Class III. Architecture and any subject, any size or process (other than Classes I. and II.). Class IV. Lantern Slides (set of 6). Eight medals (four silver and four bronze) and certificates are placed at the disposal of the Judges in the above classes. Entries close February 8, 1896. Entry forms and any further information may be obtained from R. Hauxwell, Hon. Secretary, The Avenue, Durham.

"SILVER is usually recovered from silver bromide wastes," says the *Scientific American*, "incident to photographic purposes, by mixing them with nine-tenths their weight of calcined sodium carbonate, and fusing in a crucible, whereby carbon dioxide and oxygen are given off. Metallic silver gathers at the bottom of the crucible, and a double salt of sodium carbonate and sodium bromide floats on top as a clear liquid. On cooling the crucible down to a red heat the silver solidifies, and the flux, still in a liquid state, may then be easily poured off. The silver thus obtained is of a fine white colour. The flux usually has an intense yellow colour, and still contains about ten per cent. of silver. The latter may be obtained (*Pharm. Centralh.*, xxxvi. p. 632) by mixing the flux with plenty of water and stirring occasionally to facilitate solution of the flux. The unchanged silver bromide is allowed to settle, washed by decantation, and presented for a subsequent operation."

THE South London Photographic Society's Seventh Annual Exhibition will be held at the Public Baths, Church-street, Camberwell, S.E., on Monday, Tuesday, Wednesday, Thursday, Friday, and Saturday, March 2, 3, 4, 5, 6, and 7, 1896. The following are the open classes:—J, Pictures which have previously received an award; K, Pictures not previously medalled; L, Lantern Slides which have previously received an award (sets of six); M, Lantern Slides not previously medalled (sets of six); N, Process Work; O, Stereoscopic Slides not previously medalled (sets of four). The silver and bronze medals competed for in the above classes will be awarded at the discretion of the Judges. The Society's medals will also be awarded for the best trade exhibit, and for the most useful novelty in photographic apparatus. Entry forms and further information respecting the Exhibition can be obtained from Charles H. Oakden (Hon. Secretary), 30, Henslowe-road, East Dulwich, S.E.

SOUTH LONDON SOCIETY'S CONCERT.—In place of the usual meeting, the above held their second social gathering on December 16 last, when a large audience of members and their friends were present despite the elements. A programme had been arranged for by the Hon. Assistant Secretary, and the chair was occupied by Mr. Walter D. Welford. The proceedings commenced shortly after eight p.m., and were carried through the long evening by the chairman without flag or delay of any kind likely to mar its success. A pianoforte solo for the left hand by Miss Florence Fellows deserves special mention, as also do the flute solos of Mr. G. Ernest Stanger and the recitations by Mr. Snellgrove. The violin solos of Miss Fuller call for notice in her selections from *Faust*. The comic element was well sustained by Mr. Powell, Mr. W. C. Hansell, and Mr. W. C. Boyce, and the honours of assisting at the piano were well divided between Miss Stevens, Miss Winnie Boxall, and Miss Dickinson. Other songs by Mr. Mayo, Mr. Cass, and Miss Stevens, and the recitations by Mr. Utley and Mr. Dickinson all helped to pronounce the evening one of the most successful undertakings of the Society outside its photographic work.

LUMIÈRE'S PLATINO-MATT BROMIDE PAPER.—Messrs. Forest Bros. inform us that Messrs. Lumière are now manufacturing this paper in two grades—"A" for contact printing, "B" for enlarging. The latter paper is four times more rapid than the former.

PHOTOGRAPHIC SOCIETY OF IRELAND.—In connexion with the Exhibition of the Photographic Society of Ireland, which will be held in February, 1896, it is intended to have a special exhibit of photographs representing Irish scenery, historical and archæological remains, character sketches, &c. As this is expected to aid in interesting tourists in the beauties of Ireland, the Irish Tourist Development Association have offered 25*l.* to be awarded as prizes. Many lovely souvenirs of Ireland must have been obtained by amateur photographers who have visited the Emeral Isle, and it is hoped they will be induced to send specimens of their work to this Exhibition, and not only take part in a competition for valuable prizes, but at the same time support the object this Association has in view, and so assist in spreading a knowledge of the attractions of Ireland. The prizes consist of one prize of 5*l.*, one of 3*l.*, and one of 2*l.*, and thirty certificates to those pictures next in order of merit, to which also will be given a fee of 10*s.* 6*d.* for right of reproduction. Prize-winners must allow the reproduction of the winning pictures, and the name of the photographer will be attached to the reproduction. Value of prizes may be taken in medals, photographic goods, or cash. Pictures, which must be mounted, but need not be framed, must be delivered at 35, Dawson-street, Dublin, before January 31, 1896.

Patent News.

THE following applications for Patents were made between December 16 and 21:—

TRIPOD STANDS.—No. 24,078. "Improvements connected with Tripod Stands for Photographic Cameras and other articles." H. H. STANNUS.

DARK SLIDES.—No. 24,121. "Improvements in Photographic Dark Slides for Carrying Sensitised Cut Films." H. HODGETTS.

FOCUSSING APPLIANCE.—No. 24,124. "Focussing Appliance for Photographic Cameras." J. PEARSE.

PHOTOGRAPHIC BATHS.—No. 24,141. "Improvements in Means for Preparing Photographic Baths." A. MAROUBY.

CAMERAS.—No. 24,157. "Improvements in Cameras." Complete specification. H. CASLER.

LENSES.—No. 24,278. "Improvements in Photographic Objectives." Complete specification. F. R. VON VOIGTLANDER and D. KAEMPFER.

CAMERAS AND CHANGING BOXES.—"Improvements in Photographic Cameras and Plate-changing Mechanism for use therewith." C. OLIVER.

LANTERNS.—No. 24,388. "Improvements in or relating to Magic Lanterns." S. P. FRAMPTON.

CAMERAS.—No. 24,390. "Improvements in Photographic Cameras." A. A. SMITH and J. STUART.

SENSITISED PAPER.—No. 24,440. "Improvements in the Manufacture of Sensitised Paper suitable for Photographic Purposes." W. FRIESE-GREENE.

PHOTOGRAPHIC APPLIANCES.—No. 24,501. "Improvements in and relating to Photographic Appliances." G. LECOURT and J. BOVÉ.

PRINTING FRAME.—No. 24,521. "An Improved Photographic Printing Frame and accessories applied thereto." G. HOUGHTON.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK

January.	Name of Society.	Subject.
6	Richmond	Lantern Evening. Members' Slides.
6	South London	*Hand-camera Work.* Walter D. Welford.
7	Brixton and Clapham	Seventh Annual General Meeting.
7	Gospel Oak	*Photographic Failures and their Possible Remedies.*
8	Croydon Camera Club	*Orthochromatic Photography Applied to Copying Paintings.* G. R. White.
9	Leigh	*Bromide and Platinotype.* R. Leigh.
9	Liverpool Amateur	Lantern in Use.
9	Woolwich Photo. Society	Lantern Night, for Testing Members' Slides.
10	Birkenhead Photo. Asso.	*Some Simple Optical Laws.* The Secretary.
10	Ireland	*Views in Many Lands.* Miss A. C. White.
10	Oldham	Annual Soirée and Dance.
11	Bournemouth	Lantern Evening.

Richmond Camera Club.—December 23.—Mr. Arblaster presided, and Mr. TAYLOR resumed his demonstration on the subject of

FRAME-MAKING AND PHOTOGRAPHIC CARPENTRY

by giving practical directions and showing the process of making various pieces of apparatus easily within the powers of an average amateur carpenter with a small stock of good tools. One of the most useful of the articles dealt with was a glass-bottomed dish, the construction of which was shown in detail, while examples of home-made tray racks, negative boxes, slide boxes, filter stands, &c., all thoroughly efficient for their purpose, were exhibited, and their mode of construction explained. This was the last meeting of the autumn session, and the Club adjourned until January 6.

Bath Photographic Society.—December 18, Mr. Aug. F. Perren (President) in the chair.

PORTRAITURE: PLATINO-BROMIDE PAPERS.

Mr. NAHUM LUBOSHEZ, of the Eastman Photographic Materials Company, London, attended, by invitation of the Society, and gave a most successful lecture and demonstration, entitled *A Talk about Successful Portraiture and Platino-bromide Papers.* He commenced his address by describing a picture in pure black and pure white, all intermediate tones being rendered as represented in a steel engraving. Certain photographic papers approached this condition very closely, as he proposed to show; but, in order to succeed, the operator must be master of his materials, and not allow the materials to control him. He claimed that, by an intelligent use of platino-bromide paper, the material was, or should be, under perfect control. He next spoke of the kind of developing solution most under control, and the power one could exert on a plate of ordinary speed, which was absent in the case of more rapid sensitive surfaces, when hazy shadows frequently supervened. The lecturer introduced the notion of varying the aperture of light in the objective during exposure, and showed an extraordinary example of work he had produced in this way. This was a huge enlargement by artificial light on a long sheet of prepared platino-bromide paper, showing pure black and all half-tones, and imprinted within a portion of the shadow was a twelve-inch contact print of the same subject. This was pronounced to be perfect. Numerous questions were asked by the assembly and satisfactorily answered, after which, by the aid of the black-board, Mr. Luboshez gave some valuable information on the subject of lighting in connexion with obtaining a successful portrait. He was careful to demonstrate the most suitable angle, and he inveighed against the practice of reflecting light from a false angle. At the conclusion of the lecture the CHAIRMAN heartily thanked both Mr. Luboshez and the Eastman Company for the pleasure the meeting had derived. He (the Chairman) had never heard so much valuable information given in one lecture.

Liverpool Amateur Photographic Association.—December 19.—A demonstration was given by Mr. G. A. CARRUTHERS on *Lantern-slide Making.* Mr. Carruthers showed the whole process up to the finishing of the slides in an exceedingly clear manner, and developed several plates in the presence of the audience. The demonstration was of especial interest at this time of the year, when lantern lectures, which of late years have come so much into vogue, are in full swing, and the popularity of these lectures, in their modern form, being largely due to the efforts of the Liverpool Society.

Plymouth Photographic Society.—December 20.

PLATINO-BROMIDE.

Mr. LUBOSHEZ described the process of enlarging on platino-bromide papers, showing a very splendid example of a head and bust, much larger than life size, and which had also, printed on the same sheet by contact, a print of the original negative. It was evident that in this mounting in juxtapoaition every facility for comparing results was present, and it showed but little, if any, falling off in detail between the original and its enlargement. The purity of the whites and the velvety blacks left nothing to be desired. Mr. Luboshez fully explained the means of getting good blacks, by so timing exposures that development could be fully carried ont, and not checked half way. He also made it clear how to get the utmost detail in the enlargement by means of varying the stops during the exposure, commencing with a small stop and increasing the aperture. The question of developers for bromide papers was also dealt with in a full and able manner, the lecturer's favourite being the ferrous-oxalate, on account of the definite character of its composition, the variations possible in its two or three components, and the perfect result obtainable. At this stage, on the question arising as to whether the lecturer should practically demonstrate the development of some exposed paper, it was unanimously agreed that far more would be learned by Mr. Laboshez continuing his lecture than by an experiment which could be watched by but few, and which would teach less than practical tests in one's own dark room. The lecturer then proceeded to deal with the subject of portraiture, which he illustrated on the blackboard, showing how, by defective and cross lighting, the features might be so distorted as to produce an unnatural effect, and he strongly advocated as a general principle that the direction of the rays of light be kept mainly in one axis, and distributed as required, but be not reflected. At the end of an instructive lecture, listened to with the closest attention by upwards of one hundred, Mr. Luboshez was accorded a hearty vote of thanks.

Photographic Society of Ireland.—At the last meeting of this Society, at which Mr. G. Mansfield, J.P., D.L., presided, and before a very large audience, a very interesting dual lecture, illustrated by lantern slides, was delivered by Messrs. H. Goodwillie and J. M. Keogh, the subject being

A TOUR IN NORMANDY.

The slides shown were excellent in every sense, and very uniform in technical qualities, and gave utmost satisfaction to every one present; indeed, the continual applause which greeted the pictures as they were shown on the screen was sufficient testimony as to their good qualities. These gentlemen are certainly to be congratulated on producing such superior work. The cameras they used were home-made, and were fitted with Taylor, Taylor, & Hobson's lenses, which were worked all through with the aperture at *f*-11; cut films were used for making the negatives. Over-exposure was what had to be guarded against, even in street scenes. Messrs. Goodwillie and Keogh started on bicycles, on June 23 last, from Rouen for Bernay, next day riding on to Falaise, passing through Lisieux; on the 25th from Falaise to Flers, thence to Avranches. On the 27th the ride was continued from Avranches to Mont St. Michel, from here to St. Malo, from whence the train was taken to Coutance. On the 30th they started from Coutance on their bicycles, making for St. Lo, and on July 1 they reached Caen, and next day rode on to Trouville, passing through Havre, taking in Fécamp, arriving on the 4th at Dieppe, where they remained the day, then crossing to Newhaven. At all the above-named places and along the route some interesting and fine photographs were taken. The cameras Messrs. Goodwillie and Keogh carried on their backs when not in use, and the films were placed in a small box under the saddles. From the photographic point of view, judging from the results shown, the tour was very successful, and from remarks gathered during the lecture these gentlemen appear to have had a happy time of it.

FORTHCOMING EXHIBITIONS.

1896.		
February 27-29	Woolwich Photographic Society.	
March 2-6	*South London Photographic Society.	Hon. Secretary, Charles H. Oakden, 30, Henslowe-road, East Dulwich, S.E.
,, 3-6	*Cheltenham Amateur Photographic Society.	Philip Thomas, College Pharmacy, Cheltenham.

PAPER NEGATIVES.

To the EDITORS.

GENTLEMEN.—Like two of your correspondents of late, I have lamented the disappearance of Eastman negative paper and have been careful over my stock of it (made in March and May, 1886); but I think I have found a fair substitute for it.

I was examining the texture of a piece of Wellington & Ward's bromide paper with a strong magnifier, when I found that there was hardly any perceptible grain in it. So, knowing how rapid the paper is, I at once slipped a piece into my "N & G" camera and tried it in a fairly good light on Monday, December 16, giving an exposure of half a second with *f*-11. The negative developed in two minutes. From it I took a print on the same paper, wishing to test it for giving detail; I took another exposure a day or two after, very bad light and misty, giving the same exposure, I had rather to force the development which took five minutes, but I was quite satisfied with the result. I enclose the two exposures with prints from them, all developed with the Elstree formula of metol and quinol.

If I can get the same make of paper, I shall certainly use it for work larger than ¼ plate.—I am, yours, &c., E. HEALY.

THE SAFE LIGHTING OF DARK ROOMS.

To the EDITORS.

GENTLEMEN,—I was interested to read, in this week's number of your JOURNAL, an account of some exhaustive experiments bearing on the above subject. Many people object to the irritating glare of the ruby lamp; in fact, I know persons who are so unpleasantly affected by it that they will not use isochromatic plates requiring the use of this colour. I have been experimenting for some time with different media to discover a safe and pleasant light to work by, and can recommend one or two combinations which are at once non-irritating and remarkably safe (always supposing it to be understood that no light is absolutely safe, and that reasonable protection is given to the plate during the first stage of development). My tests were more rigorous than exposing the plate in the ordinary way to the window of the lamp. The plates were put into a printing frame in contact with the different media, and exposed to the light of a Bray's No. 4 fishtail gas burner, full on, at a distance of twelve inches from two to three minutes. In actual use the light would be several inches behind the window, and with such a large burner only turned half on. Also the plate would or should be held quite two feet in front of a large window, and not less than one foot if a very small one. In this way the light action would be reduced four to nine times. There is a thick paper, first used in Leeds and district, and now sold by photographic dealers elsewhere, called canary medium. It is a bright canary colour, and absolutely free from pinholes. It is apparently coloured by a lead chromate, and is incomparably safer than any of the golden fabrics. One sheet behind a piece of fairly deep orange glass (flashed is better than pot metal), and a gas or paraffin light behind, gives a sherry-coloured light, which is pleasant and safe. If sandwiched between orange and green glass, such as is used sometimes for printing thin negatives through (not blue-green), the light is a cool green and remarkably safe, though perhaps too dim for windows less than a foot square. A brighter light, and nearly as safe, will result from substituting orange fabric for the canary medium paper. I think if the fabric were not so full of pinholes it would be quite as safe. I can easily develop isochromatic plates by the light with ordinary care; but for rapid isochromatic plates a piece of yellow tissue paper, sandwiched between ruby and green glass, gives a brown light, safer than ruby glass or fabric, and with none of its irritating qualities. The safety of the combination is further enhanced by using ruby glass, flashed on one side with orange, or by the addition of an orange pane, with scarcely any appreciable difference in colour or intensity. In this case white tissue paper or ground glass will answer quite well in place of yellow. I would just remark that I have found very deep ruby glass by itself much less safe than some of the lighter varieties, as it passes violet light, and may be actually inferior to canary medium, though not admitting a quarter the light.—Trusting these remarks may be of use to some of your readers, I am, yours, &c.,

Leeds, December 21, 1895. A. A. PEARSON.

THE NEW "STIGMATIC" LENS.

To the EDITORS.

GENTLEMEN,—In your issue of December 20 you were kind enough to give a notice of this new lens. I will thank you to give publicity to the fact that this lens is the outcome of the investigations of my friend and colleague, Mr. H. L. Aldis, B.A., who will describe the lens on January 14 at the Royal Photographic Society.—I am, yours, &c.,

THOMAS R. DALLMEYER.

25, *Newman-street, London, W., December* 23, 1895.

THE TELE-PHOTO LENS.

To the EDITORS.

GENTLEMEN,—I should like, with your permission, to correct a slight mistake in the report contained in your last issue of my remarks on the tele-photo lens at the meeting of the London and Provincial Association. The mistake is perfectly unimportant as far as I am concerned personally, but it hardly does justice to the rapidity of this lens, which is one of the most useful tools ever put into the hand of photographers.

I allude to the statement that even with the exceptionally good light on the rocks of the Farne Island I had a difficulty in developing the plates, although the fastest obtainable, and was obliged to force the development to get passable results, the fact being that I had no such difficulty, every negative coming up easily and being fully exposed; the difficulty in obtaining fully exposed negatives was in photographing small birds among foliage, &c., in this neighbourhood, ten miles from London, where the light is acknowledged to be less actinic than it is round the coast.—I am, yours, &c., REG. B. LODGE.

THE ALUM BATH WITH COLLODIO-CHLORIDE PAPER.

To the EDITORS.

GENTLEMEN,—In reply to the inquiry of "St. Clair," in last issue of your journal, will you permit us to say that the alum bath for collodio-chloride paper has been for some time back recommended in our "instructions," a copy of which is enclosed.

The action of the alum is, of course, not on the collodion film, but on the enamel substratum, the softening of which has been an occasional, though not a serious, source of trouble. The alum bath, however, entirely obviates any such difficulty, and with its assistance this beautiful process becomes one of the easiest, as well as undoubtedly the finest, of all printing methods.—I am, yours, &c., PAGET PRIZE PLATE CO.,

per WM. J. WILSON.

[With reference to the use of alum, our correspondent writes further:—

But to return to the alum. A strong bath of this, for full five minutes previous to toning, and then washed in about three changes of water, will produce, with the matt paper and the ordinary Ilford sulphocyanide bath, a very fine, rich sepia tone, which I have been unable to produce by any other means. Why it should do this I cannot explain, the alum being presumably washed out.

I found this out by laziness, having one C.C. print and several P.O.P. to tone. I placed all the lot through the same process, with above result. I have since found that a stronger solution of alum and longer steeping gives better brown.]

THE SALE OF POISONS ACTS.

To the EDITORS.

GENTLEMEN,—The humorous letter of the learned Dr. Waller in your issue of the 20th ult. is capital. The important statement that he has read Mr. Hume's letter, "with approval," is overwhelming. Such a crushing argument ought to settle the whole matter finally. And the "legally qualified," who was so "severely rebuked" by the great man, *his* statement of the incident would be interesting, if available. In a city like Edinburgh there are probably chemists who do not know everything about photographic preparations, photographic dealers who do not understand the difference between carbonates and bicarbonates, and doctors who are not capable of diagnosing and treating a case of pyrogallol poisoning. There are varieties of the human race in all professions and in all occupations, and the "unready" variety is ubiquitous. Was not a learned editor, one of the ostensible fountains of all photographic knowledge and wisdom, once caught napping on the subject of hydroxyl-monohydride?

And again, when that immaculate institution, the Medical Defence Association, prosecutes a chemist for styling himself "Doctor," or for practising medicine without the necessary legal qualification, is the culprit discharged with an apology because some learned gentleman wishes to recommend him as such a remarkably clever man?

Not probably. The learned doctor would like his own title to be protected, and that of the chemist to be pirated. Exactly so; but the ramparts of the law are not likely to crumble at the skirl of the bagpipes, even if the breath of a learned doctor is wasted in promoting the cheerful sound.—I am, yours, &c., PHARMACIAN.

HONOUR WHERE HONOUR IS DUE.

To the EDITORS.

GENTLEMEN,—I have read Mr. Ives's letter of December 14 with much gratification, and am pleased to see him hitting out straight in self-defence. I have followed his contentions as to the possibility of obtaining orthochromatic results on ordinary plates with deep interest, and think that, instead of attempting to ungenerously belittle his exhaustive researches, we should gratefully accord him the position to which, in my mind, he is honestly entitled, that of being the first to prove that it is possible to obtain orthochromatic effects on ordinary plates.

I am not at all surprised at the vigorous tone of Mr. Ives's reply to Mr. Punnett's letter (p. 735). My experiment with aurine, as obtainable in this country, prepared me for a warm retort which I was looking out for, and the latter part of Mr. Punnett's letter was an unworthy attempt to confuse the issue, if not to secure a cheap advertisement.

When your correspondents grasp the fundamental teaching of Mr. Ives's experiment that when experimenting with ordinary plates they must make sure they have a screen or light filter that cuts off the whole of the violet and ultra-violet rays, and not one which they imagine from its body or depth of colouring does this, then they may be able to contribute useful and instructive information.

I am also pleased to note Mr. Ives disclaims any intention of undervaluing the colour-sensitive plate of commerce. No one who has followed his writings on the subject could for a moment think he had any such intention. His object all along has been to show that with a suitable colour screen orthochromatic effects could be obtained upon ordinary plates as a scientific truth—a fact that has been emphatically denied—not that such plates and screens were the most practical for every-day work.

When a man gives such time and intellect as Mr. Ives has given to this subject for the enlightenment of his fellow-men, without thought of personal gain, he is entitled, not to the miserable carping criticism or reluctant admission, but our hearty, grateful thanks for teaching us something which we did not know before.—I am, yours, &c.,

Roundhay, near Leeds, December 30, 1895. F. H. BURTON.

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

To the EDITORS.

GENTLEMEN,—Will you kindly announce that the London and Provincial Photographic Association will, in future, meet at the White Swan, Tudor-street, New Bridge-street, near Ludgate Hill Station?

The Association has secured more commodious rooms and will be pleased to see any visitors at its meetings.—I am, yours, &c.,

P. EVERITT, *Hon. Sec.*

PHOTOGRAPHIC SOCIETY OF IRELAND'S EXHIBITION.

To the EDITORS.

GENTLEMEN,—I enclose two circulars containing particulars of our forthcoming Exhibition, and would consider it a favour if you would kindly draw attention to it in your next issue, particularly as regards the Champion Class, and the special class for "Irish Pictures." Last year, much to our disappointment, only one picture came from England for the former class. We trust there will be a more general response on this occasion.

As regards the class for Irish pictures, you will see that we have in view the object of drawing attention to the many beauties of Irish scenery, and we hope our friends in England and elsewhere will help us in this matter by contributing largely.

You are therefore aware that the Irish Tourist Association mentioned is a body of well-known and influential men of all ranks, who, for purely philanthropic motives, have taken up the question of benefiting Ireland by attracting tourists. It is presided over by His Excellency the Lord Lieutenant, who is taking a great interest in the matter. Our Exhibition will be held under his patronage, and he intends to be present at the opening ceremony.

We expect a very successful Exhibition, and trust you will do all you can to help us. Apologising for trespassing on your kindness,—I am, yours, &c., JOHN A. C. RUTHVEN, *Hon Sec.*

Photographic Society of Ireland, 35, Dawson-street, Dublin.

A MOMENTOUS QUESTION.

To the EDITORS.

GENTLEMEN,—When is a man too old to be a photographer? It's my misfortune to have to seek a situation, and have answered numerous advertisements, and, although terms, specimens, references, &c., are all satisfactory, yet, when I say I am in my forty-sixth year, the answers are, "Sorry, but we prefer a younger man." A bright look-out for the younger men ten or twelve years hence!

In all other professions it seems as though a man is only considered at his best about forty or fifty years of age, but photography is such a laborious and learned profession, that it seems you're played out at that time of life; a nice sort of business to bring your sons and daughters up to. What becomes of old photographers?—I am, yours, &c. STRANDED.

Answers to Correspondents.

*** *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

*** *Communications relating to Advertisements and general business affairs should be addressed to Messrs.* HENRY GREENWOOD & CO., 2, *York-street, Covent Garden, London.*

*** *It would be convenient if friends desiring advice respecting apparatus, failures in practice, or other information, would call at the Editorial Office on Thursdays from* 9 *to* 12 *noon.*

DRY PLATES.—P. C. FREWIN. Kindly inform us where you obtained the formula, page, date, &c. We shall then be able to give you more definite information.

COPYRIGHT.—E. I. We cannot say definitely if there is any copyright in the picture now. It is probable there is not, though it is possible there may be under the International Copyright Law.

CAMEO PRESSES.—D. RICHARDS. Cameo presses are supplied by all the photographic dealers. If a special die is required, it will have to be made to order; but there will be no difficulty about that.

BRASS TYPE.—D. H. HOGG. Most of the large typefounders in London will supply brass-faced type, we surmise. That will answer the purpose as well as solid brass type for the purpose you require.

PRINTING.—WILTS. The trouble has, doubtless, been due to the use of too weak a sensitising bath. Twenty-five grains of nitrate of silver to the ounce of water is not nearly strong enough. Double the strength at least. Where did you get the formula from?

ARUNDEL SOCIETY.—A. B. says: "Would you be good enough to say if you know of a Society called the 'Arundel,' that does something in the way of coloured pictures (copies of the old masters) at a cheap price? If so, please state address."—In reply: The address is 19, St. James's-street, S.W.

WRITING ON BLUE PRINTS.—W. JEFFERSON writes to know how he can write on blue prints so that the letters shall be white on a blue ground?—In reply: Use a dilute solution of carbonate of soda (the strength is not very material), and rinse the entire print once or twice in water after having written.

FLASHLIGHT.—W. WARD. The mixture will give a brilliant light, but we should advise you to be very careful in compounding it. The ingredients should be dried and pounded separately, and then mixed with a boue spatula. We should advise that they be mixed only in small quantities, and at the time of using. Why not adopt one of the many magnesium flash lamps now in the market?

GELATINE FOR MOUNTING PRINTS.—W. WOODING inquires whether "any particular gelatine should be employed for mounting purposes?"—In reply: The commoner kinds of gelatine, manufactured for culinary purposes, are more suitable than those used by emulsion-makers, since the latter are generally more or less acid. Nelson's X opaque or No. 2 soluble will be found to answer as well as any.

SENSITIVE BITUMEN.—D. D. asks if the bitumen which is sensitive to light "has to be kept in the dark when in the lump?"—In reply: This seems to be immaterial. We have employed successfully some taken from a cartload being used for the paving known as Val de Travers. It seems, when in this condition, to be very little affected by light, although, when spread out in a thin film, it is soon affected.

SHOW-CASE.—S. W. C.—Your customer has good cause to complain of her portrait being put in the show-case, and it should be removed at once, and an apology tendered without delay. If the threatened legal proceedings are instituted, you will probably find yourself in an unfortunate position, not only on account of the law costs, but damage to your business, through using your sitters' portraits for your own purpose.

LANTERN.—J. E. DODSON says: "I have a four-wick lamp to my lantern, and I have been recommended to put some lumps of camphor and "albocarbon" in the oil, as it is said to improve the illuminating power. Is that so?"—It is said to do so, but we have not had sufficient experience with oil lamps with these additions to give a decided opinion. Perhaps some reader who has made comparative experiments will give his experience.

ADDRESS WANTED.—F. COPLEY says: "In THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC for 1892 (page 579) there is an article by G. J. Clarke on *The Collodio-bromide Process*, in which he says that, if we apply to him, he will let us know where to get the emulsion that he recommends. If you could possibly let me have his address, I should be very grateful."—In reply: The address required is, or was, 52, Queen's-road, Finsbury-park, N.

HALF-TONE BLOCKS.—S. DAVIES. The only help we can give you is to tell you to get a properly ruled screen, such as that now used by the best process workers. Wire gauze is not the slightest use, if such work is desired as that turned out by the two houses mentioned. As you say, ruled screens are expensive, so are many other things in connexion with photography—lenses, for example—but they cannot be done without, if the best results are the chief consideration.

LENS.—C. S. asks: "Will you kindly inform me which type of lens you would recommend to take animals for subsequent enlargement on half-plates only, focus, about fourteen inches. I am hesitating between the following three types—(1) euryscope; (2) rectilinear; (3) single lens?"—Either of the first two named will be the best type to employ, on account of their rapidity. No. 1 will be the quickest acting when worked with its full aperture.

LANTERN SLIDES.—T. W. The albumen process has been published many times, and the results it yields are very fine. Ready-prepared plates are not made commercially, as are those of gelatine. If you want to work the albumen process, you will have to prepare the plates yourself. There is quite as much to learn in working the albumen process sucessfully as there is in the wet-collodion process. If you consider the one too troublesome, we surmise you will not think the other less so.

ENLARGING.—S. LAW says: "I have a lantern, fitted with a portrait lens as the objective, with four-and-a-quarter-inch condensers. Will this do for enlarging from quarter-plate negatives? The lantern was made by ———, whose lanterns are considered amongst the best."—The condensers will not be large enough if the whole of the subject has to be included. However, they will do quite well if only a portion of it is required, say, about three by two and a half inches.

STEREOSCOPIC TRANSPARENCIES.—W. MCLEAN says: "Will you oblige by saying whether it is or is not necessary to cut and transpose stereoscopic transparencies on glass to get the desired effect of relief in the slide when printed from the negative, or if there is any method of printing without transparency?"—In reply: It is not necessary to cut the transparency, provided (1) the binocular negative be copied in the camera, or (2) a suitable printing frame be employed. See the ALMANAC for 1887, where both methods are fully described.

STRIPPING FILMS; STAINS.—B. T. says: "I want to strip the film off some negatives to insert another figure. Will any acid do it? I have tried one or two, but they tear in places. I put some negatives by a stove to dry, and some water ran out of the pipe and splashed the negatives. The colour was like tobacco juice. It has stained one valuable negative. Can anything remove it? I have tried two days' soaking in water."—The best acid to use is hydrofluoric. With that the films will strip readily. Unless we know the colouring matter in the water, we cannot say what will remove it.

LENS.—J. FRASER says: "My nephew has bought a whole-plate portrait lens, on which is engraved, on brasswork, 'M. P. Tench, 153, Fleet-street, London. 1373. No. 4 portrait.' As I have not seen any advertisement in the JOURNAL or its ALMANAC of this firm, will you kindly tell me if it still exists, and if you can tell me if these lenses were considered good in other days, and the price of them when issued by the firm. The lens is three and a quarter inches diameter?"—The house does not now exist. Some of the lenses issued by it were very good, though they were not all of equal quality. We do not remember the prices charged, it is too long ago.

COPYRIGHT.—PURCHASER writes: "I bought a framed photograph in a picture gallery the other day for five guineas. Can the photographer sell further copies, and so depreciate the value of my own, or can I stop him? It seems, when so high a price is paid for a small print (whole-plate), there ought to be some guarantee that numbers will not be subsequently put on the market at a cheap rate."—In reply: Unless you expressly stipulated for, and secured, a transfer of the copyright to yourself in writing, you can do nothing. Certainly, as you say, the price was a big one, and, although you have not the slightest legal right in the matter, a scrupulous photographer would be unlikely to act in the way you suggest.

SPOTS.—PUZZLED writes as follows: "Could you kindly help me to find the cause of spots on enclosed platino print? The mounts are ———, and similar to what I have been using for past three years; the mountant is Glenfield starch, made fresh each day. I use pure hydro-chloric acid, one to sixty, and pass prints through six separate baths, five minutes each. I have prints on view in a very strongly lighted window, with sun and steam to contend with, which have stood the test for over three years. This print (and several others) has only been done three weeks, and shows these spots. I can only think it careless work by printer not moving prints in acid, and air bells adhering to prints, and leaving a particle of iron, to change by light action."—The spots appear to be of iron, but not produced by careless manipulation as suggested. We should rather suspect they are particles of iron rust in the washing water. Such particles are frequently met with, and in abundance at times, in water that has passed through iron pipes, main or service.

RESIDUES.—J. M. writes as follows: "I bought a quantity of residues as a speculation (about eight pounds), most of which had all the appearance of chloride of silver. This I dried, pounded, and sifted, as I have seen recommended in the JOURNAL. I sent a sample to two different refiners for an estimate of what they would give for it. In each case the sum was about the same, and very small, as they said there was little silver in it, the bulk being chiefly kaolin. On complaining to the photographer from whom I bought the waste, he told me that he used kaolin for clearing the silver bath, and that which I thought was chloride of silver in the filter papers was, no doubt, mostly kaolin. He will make me no recompense. Can I recover something in the County Court?"—No, unless the solid matter was said to be chloride of silver. Kaolin is generally amongst photographic wastes where the paper is sensitised at home. You say you bought the stuff as a speculation, and it has clearly turned out a bad one; but you have, so far as we can see, only yourself to blame.

THE BRITISH JOURNAL OF PHOTOGRAPHY.

No. 1862. Vol. XLIII.—JANUARY 10, 1896.

Contents.

EX CATHEDRÂ.

Dr. P. H. Emerson's last book, *Marsh Leaves* (London: David Nutt) is a beautiful production as books go, but in some essentials it is disappointing. It may best be described as a series of word vignettes of nature and character in the East Anglian fens. Here and there the author's prose paintings are so realistic that we seem to breathe the very air of the scenes he describes. Notably is this so of the chapters headed "A Moonlight Midnight," "First Voice of Spring," "Return of Spring," and "A Nocturne," which attest both Dr. Emerson's accuracy and minuteness of observation, and his skill in delineating the smallest details of his subjects.

* * *

Humour, pathos, and human sympathy distinguish the chapters in which the author deals with character as found in fenmen, wherrymen, and marshmen. Dismissing several chapters in which the scenes and incidents handled are either commonplace or inconsequential, it struck us that, were Emerson to devote himself to fiction, he would find congenial work in doing for East Anglia what Blackmore has done for Devonshire and Cornwall, and what Thomas Hardy has done for Wilts and Dorset, that is, to make the country, with its customs, manners, dialect, and character, the background of a series of fine novels. His obvious powers, in combination with the years of patient observation he has expended, mark him out for such an undertaking.

* * *

There are "sixteen photo-etchings from plates taken by the author" to illustrate "Marsh Leaves," possibly photogravures, but looking not unlike collotypes on plate paper. The frontispiece is "A Winter's Sunrise," an enlargement of which, we believe, was shown at the last Exhibition of the Royal Photographic Society. We may instance the "Lone Lagoon," which shows two little bits of tree-topped shore surrounded by a monotonous area of faintly inked paper, as an example of some of the illustrations that might, on account of their unintelligibility, have been omitted; on the other hand, "A Winter Pastoral" and "Bleak Winter," two snowy landscapes with gaunt trees, the atmosphere of winter brooding over scenes of dreariness, are in the author's best manner. "Marsh Leaves" is an uneven but an interesting book.

* * *

Messrs. Marion & Co., of Soho-square, ask us to state that they are open to receive designs for Christmas and birthday-greeting mounts for midget, *carte-de-visite*, quarter-plate, cabinet, and half-plate photographs. They are willing to give from ten to thirty shillings each for the designs. They also want original photographs of landscapes, seascapes, animal pets, &c., the prices of the negatives to be agreed upon. Designs and prints may be submitted to Messrs. Marion & Co. up to the 30th of the present month.

* * *

Several correspondents have lately written us urging manufacturers to resuscitate paper, coated with gelatine emulsion, for negative work. The Rev. E. Healy last week forwarded us two negatives, with the prints from them, on Messrs. Wellington & Ward's bromide paper. Both sets of negatives and prints are very good, but the negative of the architectural subject—the entrance doorway of a house—has rendered the detail with surprising fineness. For large work it is quite likely that a demand worth considering for negative bromide paper would spring up if it could be satisfied. We may add that Mr. Healy's negatives were not made translucent, though they might have gained from such treatment.

A CORRESPONDENT, who is a professional photographer, recently asked us a question with reference to photographic copyright, and was answered in due course. We also referred him to the Photographic Copyright Union, of which, when writing to thank us for the information given him, he said he "knew nothing." Our friend's ignorance cannot be ascribed to lack of effort on the part of the Union officials to make that body known throughout the length and breadth of the land, or to our own silence upon the subject. Lest, however, any others of our readers may be in the same unfortunate position, we urge them and all photographers to add to their new year's resolutions that of becoming members of the Union. The name and address of the Secretary is Mr. H. Gower, Photographic Copyright Union, London Chamber of Commerce, Botolph House, Eastcheap, of whom all particulars may be obtained. The unfriendly attitude taken up by a section of the illustrated press in the course of the *Times* correspondence last November, as well as subsequent indications from the same source, justify us in adding extra emphasis to the recommendation we give all our readers to join the Union forthwith.

* * *

QUITE a competition among plate-makers has sprung up in the invention or selection of distinctive names for their various brands of plates. Such names as convey the idea of rapidity, of emulsion, or exalted quality, are in particular request. The newest plate issued comes from Messrs. Mawson & Swan, and it is named the "Electric" plate—a very happily chosen title.

* * *

SOME years ago, a British officer in Burmah, if we remember aright, allowed a photograph to be taken of a military criminal at the moment of the latter's execution. Public sentiment condemned the act which allowed the doomed man to know that the manner of his miserable end afforded an amateur photographer the opportunity of indulging in a little morbid amusement. As neither science nor morality could be served by such an application of photography, the act was undoubtedly indefensible. But what are we to say to the latest, and certainly the most painful, use to which photography has, within our knowledge, been applied? Here are the particulars, for which we are indebted to an American contemporary.

* * *

"EARLY in November, a terrible crime was committed by a negro fiend, near Tyler, Texas, and he was soon captured by a deputy sheriff, but on the way to prison was taken from the custody of the officers by an infuriated mob, who dragged him to the public square of Tyler. An iron rail was planted in the centre, to which the negro was chained and burned to death, the husband of the murdered woman applying the fatal match. A curious feature of this horrible affair was the impressment of the local photographer to photograph the scene; the result was a series of six pictures, which form a modern human document of force and intensity. Picture No. 1 shows the capture of the prisoner at Kilgore. In the foreground are seen the deputy sheriffs who had him in charge, and from whom he was forcibly taken a little while after this picture was made. The crowd demanded that Hilliard stand for his photograph, and the idea seemed to please him, for he imagined that it was a grand and good thing for a negro to be made so much of.

* * *

"THE second photograph shows the prisoner in the little waggon in which he was eventually carried to Tyler. On the front seat, with his head turned so that his eyes are riveted upon the black brute who despoiled him of his treasure, sits the heart-broken husband. On the rear seat with the prisoner is ex-constable Meadows, who was prominent throughout the entire affair. The waggon, when this picture was made, stopped along the road near the scene of the murder, and afforded Mr. Irons opportunity to make his negative. During the taking of the picture Hilliard sat as rigid as a statue, and remarked that he had never seen a good picture of himself, and wanted this one to be a perfect likeness.

* * *

"THE third exposure was made when the cavalcade escorting the prisoner reached the public square of Tyler. He did not pose in this picture, and took no interest in it, even if he knew it was being taken. The fourth plate was made just at dusk, when a drizzling rain began, and shows the culprit on the improvised scaffold. In the fifth plate, which is a particularly striking photograph, the condemned man is seen, surrounded by his captors, praying. He was again triced up with heavy chains, and the photographer prepared to make another plate. The sixth illustration of the series was made after the enraged and distracted husband applied the match. The picture shows the beginning of the fire that consumed him, and when it was taken there were four or five thousand men, women, and children standing in the square, or occupying seats of vantage in the second-story windows or upon the substantial frame and iron awnings that prevail in every Southern town. Night had set in by the time the fire was fairly started, and photography was out of the question."

* * *

IN a country where Judge Lynch is more powerful than the official dispensers of justice one cannot be surprised that the conventional niceties of civilisation are occasionally ignored; but those who live amid calmer and more orderly surroundings may well be pardoned for wondering whether, in the case cited, the complaisant callousness of the horrible negro, the fury of the mob, the cool determination of the officials, and the willingness of the photographer, were not, in combination, responsible for subjecting the photographic art to a use so debasing and brutal as to be without a parallel.

HOW TO GET THE BEST VALUE FROM A NEGATIVE.

WE have on previous occasions referred to modern printing methods, and our present remarks will be, to some extent, supplementary to what we have before written. The growth of new printing processes has been so conspicuous, and the subject is of such great importance, that we have not deemed the trouble too great to make extensive inquiries in many directions as to the plans adopted by various workers. It is no part of our present plan to indicate any particular sort of paper as being better in artistic value than another. Granted the need to print a number of copies from a set of negatives, we wish to indicate the consensus of our correspondents' views as to the best way to do it.

Of course, if it is desired to have, for example, platinotype prints only, the printer will simply do his best with the material according to his experience. Even here it will be found that considerable range is within his power. If his negative is

weak, he will use the newest paper he can obtain; much more contrast will be given with paper a day or two old than with that kept a month or more. Such paper should be chosen for plates with images of full density. Then, if he desire the coldest tones, he will use a phosphate in his developing solution; but, if a browner shade be desired, oxalate only will be the best to employ.

Turning now to silver prints on glossy paper, the range of results is found to be varied to a most remarkable extent, and able to accommodate negatives of most widely different characteristics. As we need not point out to those used to printing from a large number of plates, the density, granting a fairly good range of gradations, is the main factor in governing the quality of the printing results. If the photographer be wedded to a particular kind of paper, he would naturally aim at getting negatives of a calibre best adapted to its peculiarities; but every practical man knows the difficulty in getting them with a close approach to uniformity; notwithstanding every care, some will be too thin and others too dense. Then to the one-process man so much the worse for his prints. But, if he be cosmopolitan in his tastes, and content to use any process that will give a good result, he will have a far better average of technical quality.

Let us suppose that albumenised prints will be made, and negatives aimed at that will best suit that method. Some negatives will be too thin. Most of us are familiar with the plan that professional photographers used to adopt under such conditions: they simply contented themselves with a very warm-toned print, one that had, as it were, only been shown the toning solution. The loss of due contrast was far less conspicuous than if a purple tone were aimed at, for the latter colour was merely presented as a muddy, non-descript colour, inartistic and offensive to the eye.

All this is now changed. An extremely thin negative will give an excellent result with gelatine printing-out paper, and a still thinner one may be used with collodio-chloride paper. But these prints do not exhaust the possibilities of refinement in the direction we are writing about. All brands of collodion paper are not alike. English makes will give good prints from a weaker negative than is permissible with foreign brands. Next in the scale of increased contrast come the gelatine papers. They also give admirable prints from negatives too thin for albumen. So clearly is this now seen that the manufacturers of this printing medium make papers adapted to various densities in the printing plate—papers to give a comparatively soft or hard character. One or the other will then be chosen, according to the depth of the *cliché*. This alternative puts a vastly increased power in the printer's hands. There is another possibility of great value in these new papers. We refer to the beautiful way in which they render the delicate *nuances* of shade in white draperies and laces. A negative that with albumenised paper will give perhaps one or, at most, two tones will give an almost infinite variety of the most delicate shadows to an extent that is a complete revelation to those not already familiar with them.

We may now set up a sort of scheme embracing the various points we have discussed. The hypothetical set of negatives we set out to print from will embrace all varieties of densities—dense, medium, thin, very thin, the faintest possible to get fair prints from. The papers to be chosen will be as follows (understanding that an exact line of demarcation is not attempted to be drawn):—First will be albumenised paper, next soft printing gelatine paper, then hard P.O.P., foreign collodio-chloride, and, lastly, English made collodion paper. This brief rough sketch is only an indication, but our readers may rest assured that a scheme of printing modelled on these lines will permit excellence of results far beyond that attainable by adhering to a single printing basis.

The Presidency of the Royal Photographic Society.—We understand that a wish has been expressed by many members of the Royal Photographic Society that, in succession to Sir H. Trueman Wood, who retires next month, Captain Abney should be elected President. We learn further that Captain Abney has already been nominated for election by some of the oldest and most influential members. Captain Abney's fitness for the position is, of course, universally recognised, and his election would, no doubt, be welcomed by the Society at large.

Patents in 1895.—The number of patents applied for last year was 25,053. This is a decrease on the number for the year before by over three hundred. Until last year there has been for many years past a steady annual increase. In 1890 the number was 21,303; 1891, 22,872; 1892, 24,166; 1893, 25,102; and 1894, 25,372. Our weekly columns have shown that there has been no lack of applications for patents in connexion with photography during the year that has just expired. Although 25,000 patents were applied for, nothing like that number will be completed, possibly not one tithe. Prior to the present Patent Act, the provisional specifications lodged with the applications were published whether the patent was completed or not. Now the case is different. Unless the complete specification is accepted, the provisional is not published, and the public have no means of knowing what the application was for except from the title.

Death by Cyanide of Potassium.—It is not often, of late, that we hear of poisoning by cyanide of potassium. Yet there have now been no less than three deaths from it recorded within a few days of each other, all self-inflicted. In two instances the deceased were photographers, and in the other, one connected with electro-plating, an avocation in which the cyanide is used in much larger quantities than it is in photography. At the inquest on the latter the post-mortem examination, it is stated, showed that the deceased had taken sufficient of the poison to kill twelve or fourteen persons. In former times there were more suicides by cyanide of potassium than there are now, but they were almost entirely confined to photographers and electro-platers. It is not the restricted sale of the salt—under the Poisons Acts—that will account for this, for both photographers and electro-platers can obtain it at will, as they always could, and it was rarely used by any one else for suicidal purposes.

The Pharmaceutical Society again.—This, at times, energetic trade protection body has been at its prosecutions again, notwithstanding the snub it recently got in the Glasgow Sheriff's Court. This time it has given our Cambrian friends a turn—though not photographic dealers. At Rhyl, on Friday last, a grocer was mulcted in two penalties and costs for selling patent medicines containing morphine. The defendant pleaded ignorance, and well he might of what "patent medicines" contain. It would be interesting to learn how many pharmaceutical chemists know the composition of the quack nostrums they sell any more than does the grocer. It would also be interesting to know how often the duly qualified comply with their own Act by labelling as "poison" all the drugs they sell which contain the scheduled things. For example, how often is "paregoric" labelled poison, yet it contains a quarter of a grain of powdered opium in each fluid drachm. However, the above and previous convictions show that pharmaceutical chemists are duly qualified to sell quack medicines, of which they do not know the composition, in sealed bottles, secured with a Government stamp, and that no one else is.

Colour Reflections.—A novel lawsuit has been instituted in Paris before the Civil Tribunal. It appears that an advertisement agent, who has an establishment in the Rue Montesquieu, recently had the whole of the front of the house painted a brilliant red. The neighbours on the opposite side of the way—a milliner, a jeweller, and a silk merchant—found that the reflection of that colour prevented their customers from properly distinguishing the colours of their wares. Consequently they have brought an action for damages to the extent of 5000 francs, and to compel the defendant to have the house painted another colour. The latter maintains that he has the right to paint his house any colour he may choose. In the end, the Court deferred giving its decision till next week. One can quite imagine the effect that a reflection from a bright red house, with the sun upon it, would have on photographs in an opposite window, particularly if they were coloured ones, and the effect would be still greater in the case, say, of coloured ribbons and the like. It will be interesting to note the way judgment goes. Houses painted in bright colours are not altogether unknown in this country, and a similar case may arise here some day.

A Concession.—Those who have had any experience in Russia with a camera are fully aware of the difficulty there is in obtaining permission for its use, and, even after that is obtained, the risk the photographer runs of being arrested as an evil-doer. However, in view of the coming coronation of the Czar, the authorities have decided to organize a "Press Bureau" to help the correspondents, artists, and photographers employed by Russian and foreign newspapers to report upon, and illustrate, the pageants, &c., attending the crowning of the Czar. The managers of foreign newspapers are to apply, in the first instance, to the Russian embassies of their respective countries to obtain the necessary certificates for their representatives. The applications are to be accompanied by photographs of the various correspondents. These the embassies will forward to the home authorities. Certificates, bearing the seal of the Russian Chancellery, and the other insignia giving the bearers permission to attend the coronation, and to pass freely, excepting on certain specified occasions, will then be duly handed to the press representatives at the opening of the coronation ceremonies. This is a great concession for Russia to make, where the press is so much under restraint, and photography out of doors almost prohibited.

Made in Germany.—Our readers, like ourselves, have, doubtless, been the recipients of a goodly number of Christmas and New-year's cards as usual. Most of us have probably been struck by the fact that a large proportion of the best and most artistic of them bear the imprint, "Designed in England, printed in Germany." Is this not humiliating? It simply means that English art is satisfactory, but English printing is not, otherwise that part of the work would not be sent abroad for execution. We have on several occasions referred to the fact that English printers are behind the Continentals in the matter of fine printing, as well as in colour work. The English printers are very conservative, and will not adapt themselves and their appliances to modern requirements. Hence modern processes—of which the finest process blocks may be taken as an example—suffer at their hands, and will not, as a rule, compare with those printed on the Continent or in America. But "'tis true, and pity 'tis 'tis true."

Anent Christmas and New-year's cards, it is a matter for congratulation to find that each year photography is coming more and more to the front in their production. It is now some few years since we first advocated that photographers should utilise their art for this class of work, and it is pleasing to find that the idea has taken such deep root, and is now so flourishing. Not only is it used for portraiture and views of local scenery, but for the reproductions of paintings. It is also gratifying to see that, except for portraits, the evanescent silver printing processes are but little used, platinotype and the mechanical ones being those chiefly employed; amongst the latter, collotype and photogravure figure largely, the last-named especially. Some cards we received were charming little pictures produced by photogravure.

Carbon Enlargements without Transfer.—As a further contribution to the recent literature on the subject of carbon printing without transfer, an old friend sends us a reference to the ALMANAC for 1887, from which it would seem that the Artigue Papier Velours, to which reference has been made more than once by Mr. Alfred Maskell, is not an absolute novelty, as something which seems practically identical with it was in use in America nine years ago. At page 133 of the volume named will be found an article by Mr. W. H. Sherman, of Milwaukie, Wisconsin, in which the following description is given of a process in actual use in his town for the production of permanent enlargements in carbon. We may add, from our own knowledge of the invariably practical character of Mr. Sherman's contributions, that the mere fact of his speaking well of the process is an argument as to its value. Here is an abstract of his description:—

"Gelatine, refined lamp-black, bichromate of potassium, and water are mixed in suitable proportions, and brought to the requisite degree of fluidity by means of a water bath. The mixture is then applied to drawing-paper, in the form of a fine spray, through the medium of an air brush, the success of the printing operations being said to depend upon the granular form of the coating that results from this mode of application, which not only permits the light to penetrate to a sufficient distance, but also allows development to proceed without loss of the middle tints. The pigment dries quickly, and the paper is then ready for exposure in the solar camera, the sensitiveness being from five to ten times as great as silvered paper. For development, the print is wetted and placed in an upright position on a stretcher covered with muslin, and water, under considerable pressure, is showered on it through a hose connected by a short hose to a double faucet supplying it with both hot and cold, temperature and pressure being under easy control. The print is finished by washing to remove the last traces of chromium salts, and, after mounting, is entirely free from gloss, and possesses an admirable "tooth"—owing to the method of preparation—for the reception of crayon, ink, or water colour in finishing." For the latter purpose a neutral grey pigment was used, instead of black, and Mr. Sherman closes his description by saying that "many artists of experience, whose practice had long been confined to enlargements produced by other methods, are now using these exclusively."

This description tallies very closely with that given some weeks since by Mr. Maskell as the method by which the Artigue paper is supposed to be made and the details do not present any serious difficulties to those desirous of experimenting in this direction. Much, of course, depends upon the proper proportioning of the ingredients of the pigmented mixture, especially upon the colouring matter being in a sufficiently fine state of division not to clog the spreading apparatus. This being seen to, with the aid of the air brush, or, failing that, one of the simple forms of apparatus sold for diffusing perfumes or insecticides, and a little care and manipulative skill, there should be no trouble in applying a tolerably even coating of the mixture to paper or any other support.

A Simple Double Transfer Carbon Process.—It has already been pointed out that the method of carbon printing without transfer, recently described by Mr. Valentine Blanchard, results, like the ordinary single transfer method, in a reversed print. Here is a simple method, which, if carefully worked, will give a non-reversed picture without the extreme difficulties and uncertainties of the double transfer. In this case, the printing is done upon the pigmented side of ordinary tissue, which is coated either before or after sensitising with a film of transfer collodion. This, although stout enough to preserve the finest tints of the proof from damage, is scarcely sufficiently so to obviate the necessity for some kind of support during development, and therefore involves a process of mounting and unmounting, which, however, present no mechanical difficulties, and do not in any way jeopardise the print.

The coating of collodion may be applied to the surface of the tissue, either before or after sensitising, by pouring on in the usual

way; but, owing to the refractory character of the tissue, it will present some little mechanical difficulty to the inexperienced. Or the tissue, after sensitising, may be squeegeed on to glass previously coated with collodion, and if a thin film of gelatine or albumen be afterwards applied so much the better. This plan, of course, involves the necessity of drying in contact with the glass, which is a slow process, but, beyond that, is without fault. The tissue is simply stripped when dry, and then presents a most perfect surface for contact with the negative. This surface, it will be observed, will be the final surface of the print, so that there is no reversal.

For development, except of very small sizes, it will be almost compulsory to resort to some form of mounting in order to prevent damage to the tissue; but this may be similar to the plan followed with Swan's original tissue, that is to say, the collodion surface may be squeegeed to paper coated with indiarubber solution, which is easily removed after the print has been developed and transferred to its final support. Flexible support may also be employed in the usual manner, and, although the process is apparently a double transfer, it is entirely free from the danger that exists with the bare or uncollodionised tissue of the finer tints remaining fixed to the temporary support. With small-sized prints, not exceeding quarter size, we have often developed the collodionised tissue by simply laying it, collodion side downwards, on a piece of moist blotting-paper; but, if the object be to work with a minimum of care, we should advise the use of one of the mounting methods. The manipulations otherwise are precisely similar to those with ordinary tissue.

LETTERPRESS PRINTING BY PHOTOGRAPHY.

In the month of February, 1890, a photographic journal, commenting upon Mr. Friese-Greene's camera for the rapid taking of consecutive photographic views, remarked that "the chief value of the machine, or of a modification thereof, may hereafter be found to be in the direction not contemplated by the inventors—at least, they have said nothing on this point—namely, in the printing of positives for book illustration, for in positive printing through a negative the amount of light can be made to vastly exceed that present in the photographic street views, so that the limit of speed, especially with improved machines as yet unborn, is at present beyond calculation. One can imagine the possibility of a practically endless band of paper being covered with some sensitive preparation as it unrolls, then passing on to the exposure platform, and afterwards into developing and fixing baths. At the present time exposing a negative on a travelling band three thousand times in five minutes would not be bad work."

These lines were no sooner read by the inventor of the camera referred to than he saw the feasibility of the idea which the editor had thrown out, and the thing began to take shape in his mind. A few months later he had constructed a model which fully answered to his expectation, and the invention was patented (1891). About the same time (October 29, 1890), this model was exhibited in the Literary and Scientific Institution of Bath by the inventor, who also read a paper upon it, which, amongst other things, contained a forecast of the use to which the invention might be turned. Speaking of the effect the original idea had upon his mind, Mr. Greene said, "My blood was fired with enthusiasm, for I thought of taking a scene in Hyde Park or in the City, where the ceaseless stream of life is never ending, by the machine camera one day, and producing in the course of a few hours a paper which could be delivered to the public showing, true to nature, all the movements of life, or anything that might be of interest which was photographed at the time. . . . . A well-known person's photograph, with his letter, could be copied by photography and put in print much more quickly than you could set up the type for the letter, leave alone a block, which would take days for the likeness, and then not be so perfect as it would come out being printed by light alone, for you could not equal the texture and detail by the block process that you could obtain by the other."

When this forecast was made, the invention had not gone beyond the rough model stage. But by that model was produced a long band of photographs printed from half-plates, with gas as the illuminant, the exposure being almost instantaneous. The invention having gone so far, and been protected by patent, the matter was allowed to rest. Many persons saw the model, and one or two were convinced that there was in it the germ of a wonder-working machine to be produced some day. It was not, however, until about a year ago that anything was done towards putting the invention to a thoroughly practical test. Then a friend of the inventor's, seeing what he called "the revolutionary character of the invention," undertook to obtain capital to give the thing a trial. He succeeded in January last in interesting Sir George Newnes in the matter, and through his enterprise the invention has been put to such a thorough and practical test that it has more than fulfilled expectation. In short, when it came to experimenting, and to different minds turning their thoughts to the same end, it was found to be possible to make great improvements in the machine, and to obtain the end aimed at in various ways; so much so, indeed, that it was found necessary to take out fresh patents.

As already said, the first experiments were made with the original model; but, as this allowed of the printing upon one side of the paper only, and from half-plate negatives, it was, at an early stage of the experiments, decided to construct a machine large enough to print eight pages of the *Strand Magazine*, namely, four on the one side of the paper and four on the other.

The machine, as will be seen from the illustration (fig. 1), consists of a box for the printing process, and a number of tanks or troughs to receive the developing, fixing, and finishing solutions. The box consists of two separated chambers for containing the negatives, the first chamber containing the negatives to be printed on the upper side of

Fig. 1.

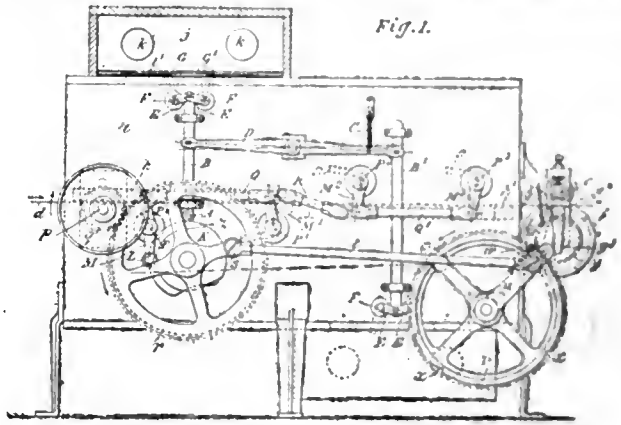

Fig. 2.

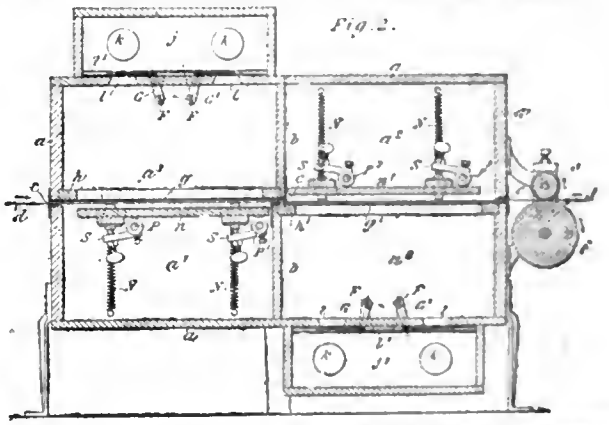

the paper, and the second chamber containing those to be impressed on the under side of the paper. Each chamber constitutes practically a dark room, with a sliding shutter to admit the light, the light being contained in a separate compartment called the light box, divided from the chamber proper by the shutter. The light is supplied by incandescent electric lamps, and may either be diffused or reflected from a mirror.

The negatives are firmly fixed in a frame, and the frames, fitted with grooves, are made to slide in and out for the purpose of

changing the negatives, &c. When in position, the negatives are in their respective dark chambers, that for printing the upper surface of the paper just above, and that for printing the under surface just below, the central line of the machine, along which the sensitised paper is carried. Immediately under the paper, in the first chamber, and immediately over it, in the second, is a platen, or pressing plate, faced with soft felt, which, when the exposure is made, presses the paper upon the under side of the negative.

The paper to be printed on is contained upon a roller, and is either already sensitised, or it may be sensitised on its way into the machine by passing through a trough charged with the necessary emulsion. It goes into the machine through a slot, and, as soon as it has filled the two chambers, by the action of the machine, the apertures in the light boxes open, while simultaneously the platens press the paper against the negatives, steadying it, and thus the exposure is made.

The instant the exposure is made, the respective apertures close, the pressure of the platens is removed, and the printed portion of the paper is carried forward, giving place to a fresh, unprinted portion. This intermittent motion of the machine proper, which is obtained by means of a pawl, is then repeated, and, with each forward movement of the paper, a portion of the sensitised surface is exposed to the light, first on the upper and then on the under side. As soon as the paper, thus printed upon, emerges from the printing box through a slot, the intermittent motion is converted into a continuous one, which is maintained uniformly while the paper is being carried successively, by means of glass rollers, through the tanks containing the developing, fixing, and clearing solutions, and so finally into an enclosed chamber or box filled with hot air or exhaust for drying.

From the description it will be understood that every section of the band of paper equivalent in length to an intermittent feed is first printed on the upper face and then on the lower face, and that, while one section is being printed from the negative in the first chamber, the next following section is being printed from the negative in the second chamber. When it is desired to print on only one side of the sensitised paper, one or other of the chambers is not supplied with a negative, and, of course, the electric lamps of the respective light box are shut off.

An important consideration connected with the working of the machine is that both the exposure and the development are being carried on at the same time, so that the operator who is controlling the machine is able to see at a glance if the picture or printing is not coming out as it should do. If there is over-exposure, he can easily, by an electrical resistance register, adjust the light to the negative. In the same way he can modify or strengthen the developer to the needs of the case.

A smaller machine, for purely photographic purposes, is made single for printing upon one side of the sensitised paper only. These can be adapted for use either with an incandescent lamp or with an ordinary oil lamp. When the latter is employed, there is no difficulty in adjusting the light to the quality of the negative.

The negatives employed may be either negatives produced directly by photography, or they may be photographs of pages of letterpress printing; or a negative may be used in which the two are combined —an ordinary photograph, presenting a view or a person, to which a letterpress description has been added, or other combination may be made.

In order to make his machine effective in a commercial sense, Mr. Greene had many chemical difficulties to contend with. For instance, it was necessary to find a cheap and efficient sensitising salt. Equally necessary was it to discover a developer which would be at once reasonable in price and speedy in action, giving a clear picture in a fraction of a second of time. Both these desiderata have been obtained, as well as a clearing solution equally effective with the others. Thus far, by these means, it is possible to make from two to three thousand exposures per hour, and to bring up the other processes to that average of working; while, with a later development of the machine, which need not be explained here further than to say that the intermittent up-and-down motion is replaced by a cylindrical arc (similar to that of the rotary printing machine), a much higher rate of speed can be obtained

It will be seen that the new photographic printing machine is very simple in construction, and it is believed that by it the cost of printing will be greatly reduced, as well as the quality of it greatly improved, especially as regards the printing of illustrated books, newspapers, &c. There are no complicated movements requiring expensive and heavy machinery; and, indeed, so little friction is there that the machine is almost noiseless. Briefly stated, the construction and operation of the machine is based upon the proper timing relatively to each other of the intermittent movement of the rollers that feed the sensitised roll of paper, the opening and closing of the time shutters, and the up-and-down movement of the pressing and steadying plates. The action is that by a couple of rollers the paper is first given an intermittent feed; then, while the paper is stationary, the platens or plates move against it and steady it, and then the time shutters open; after which the shutters close, the steadying plates recede, and the feed rollers give another feed, and so on. Simultaneously with these movements the paper already printed upon is going steadily and by a uniformly continuous motion through the developing, fixing, and clearing baths into the drying chamber.

Nor is the above the full extent of Mr. Greene's invention for the superseding of ordinary printing. By means of another machine, almost more surprising than that for printing, he is enabled entirely to do away with movable types. But to describe this machine another article will be necessary. ALFRED T. STORY.

THE PHOTOGRAPHIC OPINIONS OF ULYSSES McGILP.

THE EMERSONIAN CULT.

SOME of the possibilities of artistic expression, which are latent in every camera have once more been strongly emphasised by an assortment of *Marsh Leaves* which Mr. Emerson has, with all his wonted fastidiousness, gathered in the East Anglian lowlands, and issued in the form of a book of short essays—which are, by the way, very readable, being curious, and pathetic, and a good deal more—illustrated by sixteen photo-etchings. These last form so telling an indictment against the prevailing amateur photography, that it is worth while spending a few moments in, firstly, considering the much-vexed question as to the connexion between photographs and other monochromes; and, secondly, whether Dr. Emerson gets any nearer to the frontier line between Pencilvania and Camerania than does any other photographer.

THE EMBELLISHMENT OF NATURE.

Of course Pencilvania is a province of the brilliant empire of *Pictorial Fine Art*. Here let me add to the myriad definitions of the last term by describing it as the embellishment of Nature. Decoratively considered, art should embellish that to which it is applied; pictorially regarded, it should embellish that which it depicts.

It is in the twofold sense included in the above definition that I would compare the photography of Dr. Emerson with that of some of his more redoubtable rivals.

In doing this it is to be remembered that photography, being distinctly a tone-rendering process, and nature being all tonality and no line, the genius of a good and a true photograph must needs be most perfectly embodied where the effect is attained of melting modulations and delightful mezzo tints.

FRETFUL PHOTOGRAPHY.

But, in looking over many a photograph by those who are regarded as trusty leaders, one cannot but be struck by the frequent recurrence of prints which are at first sight more in consonance with line work than with wash. Some may be inclined to ask, Why should not this be praiseworthy? For answer, it is enough that only a real bad photograph can possibly have anything in common with a line drawing; and, moreover, the bad photograph, where it imitates the line drawing, only does so by reproducing the most unlovely and immaterial qualities of the latter. The artist with pen or burin uses his instrument to suggest forms by means of conventional lines—often outlines—which the necessities of his materials impose. These a person of suitable art culture readily—and in a measure un-

consciously—transforms into what they stand for; such a one is not attracted by the multiplicity, nor by the fretfulness, of the lines, but by what they convey, and by the dexterity of their expression. But the objects in a photograph are without definite outline; instead of which a bad photograph often presents us with a stupendous mass of niggle and trashy detail which in a degree sometimes simulates the characteristics of stipple, while at other times we get much of the ill effect which accompanies degraded line work.

Framed in Gaudy Gold.

Recall some of the photographs by some of the leaders—for instance some of those who are often chosen to sit in judgment over their fellows—and you cannot fail to notice that these exhibit a wiry, disenchanting, presentment of nature which makes one more than ever sure that it is not the common herd of art illiterates—the people who don't know their picture alphabet—who are fit to elect the dispensers of art merit. Most of us know of what the *vox populi* is capable, of which there is not a more telling example than was afforded some two or three years ago when, at a "people's" Exhibition in London, at which it was sought to awaken a critical faculty, each artisan was furnished with a voting paper on which to record his opinion as to the best picture. In the event a thumping majority voted for the vilest painting in the gallery; but *it had the largest and gaudiest gold frame.*

Take the Judges out of their gold frames, remove their mounts, wipe out their names, and then let the crowd elect afresh; how many of the present stock company would be left in? How much worse would the new lot be?

Routed by the Doctor.

What the Judges do in photographic print they in great measure approve and encourage in other people's works; hence the perpetuation of photographic misapplications. Of course the "dot and dash" school of photographers is ever so much less assertive than formerly; for Dr. Emerson, years ago, routed a whole army of these rabble art traducers. Some of them, however, still have a sneaking regard for their old bad ways; even where they have grasped the value of breadth of treatment, they have in the main most grotesquely and woefully misapplied this estimable quality.

All having art training and experience know that one cannot, when buying a camera, at the same time by an addition to the purchase money of say ten per cent.—surely not too much?—buy art capacity. Some of the very clever ones soon found this out; and so they remedied it my fitful reading mainly of the water-cum-art order of books, and by desultory, but very precious talk with other callow gropers; and so, although they have, to be sure, never arrived at the position of artist—not even in the latent sense of the word—they have picked up enough to hide their deficiencies, and to impose upon others who are just a weeny bit more ignorant or a vast deal more modest.

The Big Gun and the Throstle.

These half-artists, however, are often able to show us photographs which to a certain extent are really imposing and pleasure-giving, the explanation of which is somewhat as follows: Nature is not always obviously charming, and is but seldom dramatic and brilliantly splendid. When such rare moments arrive it takes no great artist to appreciate them, for they speak loud-mouthed, even to the most commonplace individual. The booming of a big gun is noted by more than is the song of the throstle. Take a sunset as pictured in *The old Téméraire*; if such were met with in nature, it would probably attract every camera man in the kingdom, and fairly and well photographed, could not fail to compel admiration. Such ready made pictures, which nature from time to time puts before us, have only to be copied with industry and with a mere pinch of the salt of art. Hence it is that we find so many inflated reputations. Amateurs are praised for the glory which the natural kaleidoscope periodically provides.

Loathsome Middle-class Art.

The proper criterion would be to take the weakest links—or even the average ones—in the chain of photographs by which the amateur seeks to climb; such a test would, I fear, much more than decimate the front rank; which is not matter for surprise, for it is to be remembered that the best of them so they themselves declare are painters who have failed *i.e.*, men who, having laboured to make their way with palette and pencil, have found themselves lacking in art, and have hence taken refuge in photography. This class is closely run by those who, having natural gifts, fail for want of early and sustained training. Over and above the foregoing are a very few who can boast of enough of both aptitude and training to just raise them beyond that abomination of mediocrity, the loathsome middle-class art, with which all England is at present overwhelmed.

These last are the individuals who may best benefit by the latest of Dr. Emerson's photographic manifestoes, and I hope to point out in a future article what lessons of profit there are for them in *Marsh Leaves.*

BROMIDE PAPER FOR NEGATIVE WORK.

In view of the letter in our last issue (p. 14) on this subject, it is interesting to note that Herr Watzek lately gave an interesting lecturette on this subject before the Camera Club in Vienna, and in the current issue of the *Wiener Photographische Blatter*, the organ of the Club, is an article by Dr. Henneberg, whose extremely artistic pictures at the Salon attracted considerable notice, on the same subject. Dr. Henneberg used Eastman's extra rapid bromide paper up to 15 × 12, and he points out that it possesses all the advantages of celluloid films, viz., lightness, non-fragility, absence of halation, and the power of printing from both sides of the paper, with a further advantage that it can be obtained without trouble in any desired breadth in rolls of about seven and a half yards; and, further, it does not curl and roll like celluloid films, and how easy it is to retouch and fake with pencil or brush, and how much cheaper than plates or films.

The grain, which might be an objection in small sizes, is not noticeable in the larger, as usually these are printed on rough papers.

With regard to the practical work, development is carried out as usual, and it is not necessary to use either an acid fixing bath or a clearing solution. It can be intensified without trouble with uranium, and for reduction the well-known hypo and ferridcyanide can be used, but great care is required, as the solution acts at the back as well as the front of the image, penetrating as it does through the paper.

To render the paper transparent, Henneberg suggests the use of vaseline oil applied with a bread brush to the paper only. He states that negatives thus treated print as quickly as glass negatives, and they are best kept between stearine paper under pressure.

FOREIGN NEWS AND NOTES.

Photography in War.—The Japanese, as is probably well known, utilised photography to a considerable extent in the late war with China, and they are now about to dispatch some of their official photographers to Europe to inspect the system of photography in connexion with the war departments of European countries. They have also decided to send a photographic survey department to Formosa, to collect reliable data as to the topographical features of the island, the habits of its people, &c.

Chlorides in the Developor.—According to L. Tranchant the soluble bromides, which have hitherto been so much used for restrainers, can be replaced with advantage by some chlorides and organic acids or their salts, because the bromides dissolve the silver bromide and thus give rise to defective negatives, as the most delicate details may be attacked. He states that the chlorides of sodium, potassium, ammonium, and zinc restrain without dissolving the silver salt, as do also sodium acetate, acetic and malic acids; cupric chloride acts as a slight solvent. Arrayed in the order of their restraining powers, the salts are cupric, zinc, sodium, and ammonium chlorides, acetic and malic acids. A 1 per cent. solution of cupric chloride, a 5 per cent. solution of zinc chloride, as well as 25 per cent solution of sodium and ammonium chlorides, are equal in power to a

20 per cent. solution of potassium bromide, 10 per cent. solution of acetic and malic acid, on the other hand, only equal 1 per cent. of potassium bromide. To use zinc chloride, sufficient sodium carbonate must be added to cause a distinct precipitate of zinc carbonate, and he finally concludes his note by recommending ordinary salt or ammonium chloride. It is obvious that these statements apply only to gelatino-bromide plates, as chloride of silver is readily soluble in most chlorides, even to as high a percentage as ·58 in calcium chloride, as pointed out by Hahn.

Photographic Perspective.—Professor Schiffner points out that the smallest angle under which an object is visible is generally assumed to be one inch; when viewed at the distance of normal vision, about ten inches. According to Mertens, the angle at which an object is distinctly seen is about 27°. The angle of the eye to see an object clearly is 45°, the mean is 36°, and a picture is generally viewed at a distance equal to one and a half to twice the longer base of the picture, so that the generally accepted focus of a lens as one and a half times the longer base of the plate is correct. With these data, b, it is possible to reckon out, with any given object, distance g, the focus, f, of any lens which will answer to these requirements, by the formula $f=\frac{gb}{g+f}$; or, for a lens of known focus, the correct distance of object $g=\frac{bf}{b-f}$. He also points out the importance of the correct position of the point of sight, which should be below the horizontal middle line, as it is far easier to look up than down. Objects which should appear natural should appear for the greater part above the horizontal line of sight. The horizon should be about one-third below the middle line of the picture.

Anaglyphs Perfected.—M. Louis Ducos du Hauron, the original inventor of the anaglyph, describes in the *Revue Suisse* how he has still further perfected it, so that it gives not only the idea of solidity, but also "une sensation de polychromie complète des plus agréables." This is a distinct advance to obtain colours and relief, and it is attained in two different ways: either by the use of two stereoscopic negatives, or by using three negatives, two of the latter not being taken stereoscopically, and printed one over the other, whilst the third fulfils the usual requirements of stereoscopic work. By the first method, the negative for the right eye is taken through a green screen, and printed in red, madder lake; the negative for the left eye being taken through a red-orange screen, and is printed in Prussian blue, the prints being viewed through spectacles with turquoise blue and ruby red glasses; this is said to give all the colours. The second method is more complicated, and is founded on the ordinary three-colour process, the two prints, negatives from which are superimposed accurately, are taken with blue-violet and green screens, and printed with chrome yellow and madder lake, the third negative being taken through an orange-red screen, and printed in Prussian blue. The same coloured spectacles are used as for the first method. This method has also been adapted to lantern projection.

ON A SIMPLE METHOD OF PROJECTING STEREOSCOPIC PICTURES ON THE SCREEN BY MEANS OF TWO ORDINARY LANTERNS.

[London and Provincial Photographic Association.]

I THINK we can fairly claim that my system of getting a stereoscopic effect on the screen has not been shown to an audience before in this country. When we first saw the anaglyphs, the invention of Mr. Ducos du Hauron, we thought that something of the sort might be applied to the lantern, so set to work for that end. I tried a great many different ways, dyed my films in all sorts of colours, red, blue, yellow, used all the various coloured gelatines that I could get, had heaps of carbon tissue made in various ways to try and get the right colours, but with poor success, as you will see. The great difficulty was to get the proper colour value in the different pigments that we used, and in the spectacles through which it is necessary to look at the picture. If these pictures could be produced in their proper colours in this way, they would have a much better effect than can be got with a black-and-white picture coloured by means of coloured glasses. Gelatines are of no use, you cannot get them of the proper colour value; and, if you could, they will not stand the heat of the lantern, for in a few seconds they blister up and burn, so I had to fall back on the coloured glass. And, to show this system of stereoscopic projection, as I have said, it is necessary to have two lanterns, either a pair side by side or a biunial. In the one lantern you place one half of a stereoscopic picture, and in the other lantern the other half; and behind one picture you place a red glass and behind the other picture a green glass. Now, when these two pictures are projected together on the screen, they are made to cover one another, so that we see an indistinct mass of colour caused by the two slides occupying the same place on the screen. If the coloured glasses are of the right colour value, and we cover up the green glass in the left eye, we shall see only one picture, and that all red, though there are still two pictures on the screen; now cover up the red glass in the right eye and look through the green glass of the left eye and we shall see only one picture, and that will be green, though the red one is still there; now look at the picture through both eyes of the coloured spectacles, with a red glass in the right eye and a green glass in the left eye, and we shall see that the two pictures that have been projected by the two lanterns on to the screen are made to blend, not only into one another, but to stand out in bold stereoscopic relief.

Let us consider for a moment the cause of this. We have two pictures of the same subject taken with a pair of lenses separated at two or more inches apart, so that one lens takes one picture at one angle, and the other lens at another angle; now, if we look at the picture so taken through an ordinary stereoscope with prisms, we get one impression, and so see the object photographed as we do in nature; just the same with the system that I shall presently show you. If you understand the principle on which this new stereoscopic projection is shown, you will more easily grasp the cause of the effect. As I have said before, we have two similar pictures of the same subject, one taken to the left and the other to the right, these two pictures being covered with coloured glasses, one red, the other green—and we want to see each separately. In nature we see more to the left with the left eye, and more to the right with the right eye—we want to see these two pictures as one. To do this, we look at the left picture through a glass of the same colour as it is covered by, and the right picture by a coloured glass the same colour as it is covered by. So we get two pictures conveyed to the eyes separately, at the same time, with the result as in nature, everything standing out in bold relief; so much so, that, in the special stereoscopic pictures that I have prepared to show you this evening, the plants and other things stand out in such bold relief that one feels as if you could put your hand through the leaves and pick the flowers. To get the best effect the subject should be large, that is to say, when shown on the screen, as near life size as possible. I will show you some interiors—they are so real that you feel as if you must get up and walk down the long corridor and sit on one of the seats; I will show you a party of travellers crossing a glacier with their ladders and ropes—you will see how real it is. In looking at this picture in the flat, you get no idea of the difficult task these men have in hand. I have also two or three copies from an old set of diagrams, published many years ago, for showing objects in true perspective with stereoscopic effect, notably the one of a cross; if you look at it from one side of the room, you will see the front bar appear as if it stood right out and you could take hold of it with the hand; walk across to the other side of the room, and the bar will appear to follow you. This is very curious. Another example: a figure of myself, seated in a chair. If this is viewed at an angle, you seem as if you can see almost round the figure. The adaptation of this system has been brought within reach of any exhibitor by Messrs. Newton & Co., of Fleet-street, and put upon the market at such a price that I hope we shall soon see it introduced into every public lecture and entertainment. A few pairs of pictures thrown on the screen will give a far better idea of a place than all the description possible, so I will not occupy any more of your time, but at once proceed with the exhibition.

T. E. FRESHWATER, F.R.P.S.

A NEGLECTED METHOD OF RETOUCHING.

THE higher the artistic pretensions, says J. Gaedicke, in the *Photographisches Wochenblatt*, with which we may endeavour to invest a photograph, the more difficult will it be found to justify the almost universal practice of retouching by means of dots and short strokes. At the present time a freer and broader treatment of the picture is required. Laborious working up easily ends in a tortured expres-

tion, and, as the methods of retouching now followed are excessively laborious, the results often have a tortured, stiff, and dull effect.

Photography depicts in even tones that blend with each other in the most delicate manner, and it is therefore natural that retouching should also be done in even, soft tones. In place of this, strokes and dots are used, which are crowded together in enormous quantity to present to the naked eye the appearance of even tones. This may be approximately attained in albumenised prints, but not in collodio-chloride.

It is patent that the general effect may be lost sight of in this way, because attention is concentrated upon very small areas. The loss of time, too, in brightening up large surfaces very often leads to sins of omission, and the possibilities of a better interpretation are lost.

In contrast with this, we would recommend a more general use of the stump in conjunction with powdered graphite or finely scraped lead pencil.

A paper stump is preferable to one of leather, and may be bought of any dealer in artists' materials, or they may be made of unsized paper cut in long strips and rolled up to the thickness of a lead pencil. The last layer of paper must be fastened down with fish glue or gum to prevent the stump unrolling itself. Both ends of the roll of paper are then sharpened with a penknife, which may be repeated as often as the point becomes too blunt. A broad as well as a sharp point should be prepared.

The stump is now dipped into the graphite, and rubbed upon a sheet of paper until it is equally distributed over the point. The most delicate tones and the softest of lines can then be produced in perfect harmony with the tones of the negative. Portions of the picture that are too sharp may be moderated and made subordinate. Large areas may be brightened up in the quickest manner.

A still larger number of effects may be attained if the back of the negative is taken advantage of. To this end it is coated with a matt varnish, and the heaviest of shading can be rubbed on. By such means portions of the picture may be blocked out altogether, if occasion requires.

In retouching the film side of the negative, it is best to roughen the surface of the varnish by rubbing, or to use a retouching medium if heavy shading is required.

The stump will be found sufficient for most of the retouching, and only for very fine work will it be necessary to use the pencil Under any circumstances, the stump will effect a great saving of time, and, as more attention can be given to the general effect, the stump should not be absent from any retoucher's desk.

PHOTOGRAPHIC MOUNTANTS.*

[American Journal of Photography.]

Plain starch paste is the oldest and most universally used paste for mounting albumen prints. It still remains the most simple and cheapest medium for the purpose, and is certainly the least injurious, provided the precaution is observed always to use the paste fresh, never after it commences to become sour.

A different condition, however, exists where the prints are made upon the modern emulsion papers. Where the paper support of these emulsions is not too heavy, they show little or no tendency to curl, and may be mounted wet in the usual manner, a small percentage of glue being added to the paste, care being taken that there is absolutely no acid reaction.

Heavy papers that have a natural tendency to curl, or Aristotypes with a high gloss, require to be mounted dry, and require a different paste. A mountant is here required having a greater degree of adhesiveness; at the same time it must not penetrate the paper, or it would destroy the high gloss of the print.

To overcome this difficulty has resulted in the publication of many widely different formulas for mountants in the various photographic periodicals, and in every case it is claimed a perfect mountant has now been discovered.

Upon the other hand, manufacturers and dealers have put proprietary mountants on the market, and sold them to unsuspecting amateurs at exorbitant prices, although they by no means fulfil the requirements for a photographic mountant.

These requirements are as follows: In the first instance, the mountant should have a greater binding power than ordinary paste.

*Translated from the German and amplified by Julius F. Sachse.

It must show a neutral reaction, or nearly so, and in no case should it show a marked alkaline or acid reaction. Further, it must not contain any substance which will prove injurious to the photographic image, such as the mercurial salts so frequently added to commercial mountants as an antiseptic or preservative.

A useful, safe, and practical mountant must be cheap and easy to manipulate, and be slow to decompose or spoil. For glacé or matt Aristo papers it is requisite that the paste shall not penetrate through the paper, else the enamelled face of the print, be it glacé or matt, would suffer.

In the photo-chemical laboratory of the K. und K. Lehr von Versuchs Anstalt for photography and reproduction processes at Vienna, a large number of formulas and mountants have been tested, with special reference to their composition and fitness for photographic purposes. The deductions from these experiments show the following results:—

Starch Mountants.

If starch is treated with aqueous alkali under certain conditions, it swells and forms a semi-transparent, viscid mass, having strong adhesive properties. This product is variously known in commerce as vegetable glue, glutine, triticine, collodin, &c. Most all of these preparations show a strong alkali reaction, and upon this account are useless for photographic purposes, notwithstanding their great relative adhesive properties.

In cases where the product is neutralised with acid, it proved at the expense of the adhesive properties. Consequently, on account of this effect, all advantages of these vegetable glues over ordinary starch paste are lost when the former is in a neutral condition.

Far superior, for photographic purposes, are mountants composed of starch in combination with the gum arabic or dextrine. These mountants have the advantage over all gelatine mountants that they are viscid or pulpy at an ordinary temperature, and at the same time possess a relatively strong adhesiveness.

An excellent mountant of this nature is made as follows, and which answers for mounting ordinary photographs, such as albumen, Aristo, platinotype, and colloidin prints, as well as glacé or matt Aristo prints, in all their variety, as it has the advantage of not penetrating through the paper.

White gum arabic	35 grammes.
Water	100 c. c.

After the gum is dissolved strain through a piece of muslin to remove any possible foreign substance, then add

Starch	30 grammes.

Stir this in a mortar or suitable dish, and heat the whole mass over a water bath until the paste has reached the required consistency.

The addition of a little white sugar has proven of advantage.

The substitution of dextrine for gum arabic, somewhat lessens the adhesive properties of the mixture.

Compounds of dextrine, alum, sugar, water and carbolic acid (as an antiseptic) have also proven of service and value in these experimental tests.

A good formula is as follows:—

Dextrine	60–90 parts.
Alum	4 ,,
Sugar	15 ,,
Water	120 ,,
Carbolic acid, 10 per cent.	6 ,,

Mixtures of Starch Paste and Dextrine

in various forms have of late been brought into commerce and sold for photographic purposes. One of the most widely advertised pastes of this class is one labelled "Concentrated White Paste." This paste represents a viscid white mass, which, according to careful analysation, consists of water, starch paste, dextrine, boracic acid, glycerine, and a small portion of thymol as an antiseptic.

Gelatine or Glue Mountants

are absolutely unfit for mounting photographs. As the gelatinous mass has to be liquefied by heat for use, it readily decomposes, and, if diluted to a proper consistency, has the fault of penetrating through the paper.

The simplest method to overcome the latter drawback, and at the same prevent rapid decomposition, consists in adding to the liquid glue a small quantity of amyl-alcohol (fusel oil).

Liesegang recommends as mountant for his glacé Aristo prints a paste made from good glue (Cologne glue, free from acid) to be first swelled in water, the surplus water to be poured off, to which is to be added, under constant stirring, one c. c. of amyl-alcohol for every 30 c. c. of the dis-

solved glue. This mountant can be diluted with water. It sticks well, but must be used warm. The disadvantage in its use is the strong smell of fusel oil that it imparts to the print.

COMPOUNDS OF GLUE AND STARCH PASTE,

to which a greater or less quantity of turpentine is added, possess strong adhesive properties, and have frequently been recommended for photographic purposes.

An excellent mountant of this class can be made as follows: 40 grammes of good (Cologne) glue is soaked in 100 c. c. water and melted over a water bath. When from 80 to 100 C., 40 to 50 c. c. of dissolved starch is added, the mixture being constantly stirred. When these have united and formed a homogeneous glutinous mass, 10 c. c. of turpentine is added gradually until the whole mass forms a thick, brownish, sticky liquid.

This mountant, unfortunately, must also be applied warm. The addition of the turpentine, as proven by many experiments, in no manner affects Aristo prints.

Good results, with extraordinary adhesiveness, were obtained according to the process patented in Germany by E. Wiese, of Hamburg. This consists in a liquefaction of gelatine or glue by means of chloral hydrate (D. R. P., No. 77,103).

When gelatine or Cologne glue (a bright-coloured, very adhesive glue) is steeped in water and then melted, and a certain quantity of chloral hydrate added, an adhesive paste results of great strength, which has the property of remaining liquid, and, as proven by experience, is well calculated for photographic purposes.

A good formula for preparing a mountant of this class is as follows:—

Gelatine or Cologne glue	40 grammes.
Water	120 c. c.

The glue is to be steeped in the water, and then dissolved over a water bath.

Chloral hydrate	20 grammes

is then added, and the whole mass heated for some time. This results in a clear, sticky fluid, which can be neutralised with a few drops of a soda solution.

This mountant has the advantage that, with its great adhesiveness, it does not go through the paper.

Above mountants, continues Herr Valenta, are only to be recommended in cases where starch paste fails to fill the requirements; for instance, with Aristos having a glacé or matt surface, &c.

As all the above recipes have been carefully tested in actual practice, they may be relied upon without hesitation in all cases where their use is desirable or necessary. PROFESSOR E. VALENTA.

"PHOTOGRAPHY" UP TO DATE.

THE Vienna correspondent of the *Daily Chronicle* says:—"A sensational discovery, which, if the reports are confirmed, is likely to be attended by important consequences for physical and medical science, is spoken of in scientific circles here. A new conductor of light has been discovered by Professor Routgen, the well-known physicist at the Würzburg University. So far his experiments have resulted in the discovery that light penetrates wood and the flesh of men and animals, without, however, penetrating bones and metals. The professor succeeded in photographing metal weights placed in a shut-up wooden case. The photograph sent to Vienna shows only the weights, but nothing of the case. Another photograph of a man's hand shows only the bones, while the flesh remains invisible. Professor Routgen's experiments are conducted in the following way: He takes a so-called Crooke's pipe—viz., a well pumped-out glass pipe, with an induction current going through it, and by means of the rays which that pipe is emitting he photographs on ordinary photograph plates. In contrast with the ordinary rays of light those rays penetrate wooden and organic matter and other opaque substances, just in the same way as the ordinary rays of light penetrate glass. Experiments were also made in photographing hidden metals with the apparatus shut, and produced equal success. The rays penetrated not only the wooden case containing the metals, but also the cover placed before the plate of the apparatus. The scientific world here is much agitated by the discovery, which it is believed will be of far-reaching importance for many branches of knowledge. Already in its present stage it will be an excellent expedient for surgeons, particularly in cases of complicated fractures of limbs, in searching for the bullets of the wounded, &c. The photograph will show not only an exact picture of a fracture, or the situation of a bullet, but spare the patient much painful manual probing with the sound."

Our contemporary thus comments on the Professor's "discovery":—"'Spook' photographs may take a back seat; everything must be conceded to be now possible to the camera, if we are to credit all that we hear from Vienna. Our correspondent in that capital tells us to-day of a discovery by Professor Routgen, of Würzburg, that lovely old city on the Main, whose university celebrated its tercentenary fourteen years ago, whose cathedral goes back to the twelfth century, and whose inhabitants show to this day the strain of much Roman blood. This gentleman does more than 'look you through and through'—he gets a likeness of your very skeleton. Flesh and blood are no barrier to the lens of his camera. He can picture instead of probe for a bullet that has entered, and show on a glass plate the mischief it has done to the bony structure. That is a good deal to do, we cannot help thinking. But this is only as the beginning of the newest wonder of the world. He can photograph metals even when they are covered with wood. A tin soldier, for example, with a bucket inverted over it, might come out on the plate as a real live Pomeranian Grenadier or Coldstream Guardsman, and Kaiser Wilhelm himself might be mistaken for an effigy of brass. But the wondrous camera of Würzberg will do more than this, it will do these surprising things even when a cover is put over the lens. Many years ago Asmodeus, the devil on two sticks, was represented as taking the roofs off houses to see what was going on inside. Presumably this process will no longer be needed in the case of houses furnished with Venetian blinds, provided those inside have only some metals about them such as watch chains or brooches. Fearful possibilities lie that way. But seriously we shall all have to begin to mind our p's and q's if this development of photography goes much further. 'Stone walls do not a prison make,' as the poet observes, but, if the camera can already see through wood, why not in time through a brick and a half? We shall hope to find some of these extraordinary negatives in London soon, for 'seeing is believing,' as the proverb hath it."

AN IMPORTANT CASE.—ILLINGWORTH *VERSUS* DRAYCOTT.

THIS case was tried at the Birmingham Winter Assizes, before Mr. Justice Cave; Mr. Hugo Young and Mr. Pritchett appeared for the plaintiff, and Mr. Jelf and Mr Disturnal for the defendant.

Mr. Hugo Young, in opening the case, stated that it was an action brought by William Illingworth, photographic operator, against John Arthur Draycott, carrying on business at Birmingham, Northampton, and Walsall, for damages for wrongful dismissal. The plaintiff, having entered the service of defendant in 1891, managed the Northampton business at a salary of 4*l.* 4*s.* per week, until 1894, when plaintiff, well knowing his ability, proposed that he should assume the management of the Birmingham establishment for a period of four and a half years, at a salary of 5*l.* 5*s.* the first year, 5*l.* 15*s* 6*d.* the second year, and 6*l.* 6*s.* thence until the expiration of the term, plaintiff not to practise within eight miles of either of defendant's establishments for five years after the termination of the agreement, this agreement dating from October 1894. After about three weeks' service at Birmiogham, defendant frequently complained, and eventually, under a clause in the agreement, gave plaintiff one month's notice. This action, counsel complained, was not justifiable, and it remained for the jury to assess the amount of damages they would award the plaintiff. In assessing the amount, it might be pointed out that they, the jury, had to estimate the probable amount that plaintiff might earn. The photographic business was at present in a very depressed state, and, since Mr. Draycott had dismissed plaintiff, the latter had only been able to secure a four weeks' engagement at 2*l.* 12*s.* 6*d.* per week, and nine weeks' employment at 4*l.* 4*s.* per week; this, deducted from the salary that plaintiff was entitled to under the agreement, for a like period, showed a deficit of about 56*l.*, and at this rate the total loss that plaintiff might suffer, roughly and moderately speaking, would amount to about 500*l.*

William Illingworth, the plaintiff, entered the box, and admitted a clause under which he might be dismissed, for non-observance of agreement, gross mismanagement or neglect, inebriety, want of skill, or misconduct.

Mr. Jelf (for the defence) submitted that, to be a successful photographer, one must be a man of many parts; not only must he understand the technical details, but must humour and please the customers, treat them tenderly, gently, and respectfully, and in his conduct of the business, exercise such care and control that nothing should be sent out which could occasion harm to his master's business. These were, no doubt, high attributes to expect in one person, but it was on account of these high expectations that the defendant was agreeable to pay the handsome salary he was prepared to pay. It was not disputed that plaintiff had ability, but he must, under the agreement, exercise it; that it was his duty to humour the customers, and in every way satisfy them; that he should call witnesses to show that plaintiff had offended in many ways Mr. Draycott's customers; that it was his duty to supervise the forwarding of all prints; that many had been sent out that would bring discredit upon the establishment; that some of nude infants were of such a character that they might be deemed indecent, and had given great offence to parents of the children; that there were incidents where the plaintiff had shown want of skill and spoiled negatives; that such proceedings were calculated to bring discredit upon a high-class business, and rendered it imperative that Mr. Draycott must at any cost dismiss

plaintiff before his business had suffered further loss, and he submitted that, as business men, he had no doubt that the jury would unhesitatingly support Mr. Draycott in the course he had taken.

Counsel proceeded to cross-examine plaintiff, and submitted several examples of work. With regard to the photographs of nude children, he admitted they were not high class, but submitted that, under the circumstances, they were as good as could be obtained. His instructions from Mr. Draycott were, when any customer came, under any circumstances, Get their money and make an exposure, and, if not satisfactory, they can sit again. This led to some of the failures shown. With regard to the nude infants, which had been termed indecent, he did not agree with that term, but would not say he considered them decent; but he was not wholly responsible for them, as the mothers desired nude photographs; but he would not swear that the mothers wished that particular attitude. With regard to the group of cricketers, he considered it good under the circumstances, but, apart from that, not high class. The group standing in the sun caused them to close their eyes, and many had dark shadows from their hats, &c. He did not take it in front of the pavilion, because a streak of light shone brightly upon one part of what would have been the background. With regard to the Bentley group of four young ladies, he was aware one was about to go abroad, and it was very desirable to secure a good negative. He made three exposures, and, as it was late, he left them in the washing water from Saturday until Monday, under a low glass roof, in hot weather. On Monday they had greatly increased in density; he attempted to reduce with red prussiate of potash and hypo, and, being unsuccessful, used chloride of lime. This destroyed two negatives, but the third was all right when taken from the washing water on Monday night, but, on the following morning, the film was broken up and spoiled. He had made 800 exposures, and of these 153 had resat once and twenty-five had resat a third time. Was not aware of complaints, or of letters of complaint—except one, which he answered.

The portrait of Mr. and Mrs. Edmunds was not good, or what he cared for, but they brought an American photograph and wanted theirs to match. Re-examined by Mr. Pritchett: Would find it very difficult to obtain a situation without a character; did not personally send out the alleged indecent prints. It is not at all unusual to have resits or complaints. He did his best, and had treated scores of negatives as he treated the Bentley group, but never before had any mishap.

His Honour here interposed that the witness might be asked questions as to damages, but from the nature of the defence the onus of proof rested with that side, and Mr. Hugo Young said that he had no witnesses to call; and that closed his case.

Mr. Draycott entered the box, admitted the agreement, but had to complain so many times, and found such injury to his business likely to arise from plaintiff's want of tact and skill, that he felt compelled to dismiss him; he paid a high salary to ensure efficiency; he only sold one of the cricket groups, they were so bad, whereas he had originally thirty ordered at 4*s.* 6*d.* each. With regard to the nude infants, he considered they were filthy, and calculated to do him infinite harm, as one customer mentions it to others and the matter spreads. He repudiated the idea that he had in any way passed the photographs complained of, and, after the receipt of thirty-five letters of complaint, felt that he must put in force the clause of the agreement and dismiss plaintiff, but it was in no way to save his pocket.

Cross-examined by Mr. Young: He had had five operators in about five years, as he could not secure all the feature he desired.

Miss Liechti, of the reception-room, had showed the letters of complaint to plaintiff.

Mrs. Brewer did not desire her child nude, in fact, bought a shirt on purpose to cover it. Plaintiff suggested taking the shirt off. She did not get what she wanted, and was annoyed at what was sent. Mr. Draycott eventually took it satisfactorily.

Dr. Arkwright took his baby to be photographed; he wanted the child sitting up, plaintiff took it in a chair. He had nothing to complain of his manner, but the photograph was not satisfactory.

Mrs. Terry had her portrait taken, but, as her husband did not consider it satisfactory, she returned it, and complained, and she thought the plaintiff was unduly "sharp" with her, and gave her the idea she ought not to have complained.

Mr. Chapman, who took his daughter to have a portrait taken, complained that plaintiff capered about, and got up to such antics that he frightened the child. He was there nearly an hour, and told the plaintiff that, if he could not do it, he would go elsewhere.

Mr. E. C. Middleton, called as an expert, condemned leaving the plates in water from Saturday until Monday night, and considered it risky; in fact, in view of the value of negatives of the Bentley group, grossly negligent; could not understand any great increase in the density of the negatives left in washing water, and believed red prussiate of potash and hypo an entirely satisfactory reducer in skilled hands, and would not have used chloride of lime, on account of its great action on the gelatine film. He would never take a group in strong sunlight unless there were other considerations more serious.

Mr. Thomas Fall, of Baker-street, London, strongly condemned the prints of babies submitted and some others; they were beneath criticism from an art point of view. Admitted of some prints that he had seen worse. The cricketing group he would have refused to take rather than run the risk of producing the effect plaintiff had. In the case of the Bentley group, knowing the importance of the matter, he would, to ensure a good result, expose six plates. The treatment of the negatives he condemned; had never heard of the use of chloride of lime, and would never need to use it. On the question as to how many resits would be a fair percentage out of 800, the witness declined to commit himself to any definite opinion, so very much depending on the practice of the studio, for, while one man almost encouraged resits as an advertisement, another distinctly discouraged them, and granted them with extreme reluctance.

Counsel having addressed the jury, his Lordship proceeded to sum up. He pointed out that, only too frequently, he was afraid, there was more or less dissatisfaction expressed at the efforts of the photographer. People did not say that it was not like them, but that they did not like the picture; but that did not of itself point to want of skill in the operator. It was not within human possibility to please all, and, naturally enough, some complaints had been made. But were they excessive? No witness had said they were. That in any one's experience some bad results must naturally be expected, and it was obviously unfair to get together some few out of many hundreds, and hold them up as fair samples of Mr. Illingworth's work. With regard to what had been termed the indecent prints, he saw nothing of beauty in a naked child, and doubted that such objects could be made to show art; and, although he should never desire such things, if parents come and say "I want them," then he thought that the operator was only exhibiting that forbearance and effort to please expected from him if he endeavoured to grant their request. With regard to the indecency, a limb might be moved, and a result obtained that was not desirable, but it did not show want of skill on the operator's part, and was met by Mr. Draycott's order, "Get their money and do something; and, if it is not liked, they can sit again." With regard to the cricket group, Mr. Illingworth says, "It is not high class, but the best I could do under the circumstances," and no witness could contradict this. With regard to the Bentley group, an unfortunate error had been, he was inclined to think, made, and it was, no doubt, especially under the circumstances, annoying to Mr. Draycott. "But, gentlemen, it is for you to consider if a single error such as this is sufficient to justify the defendant in dismissing this man, and sending him adrift without a character, and putting him in such a position that, in seeking another position, he has to say, in reply to the question, Why did you leave your last situation? "I was dismissed for incompetency." It would seem an unreasonable punishment, and out of all proportion to the error. If, then, gentlemen, you find the defendant has failed to support his action to your satisfaction, it remains for you to award such damages as you may consider the plaintiff rightly deserves."

The jury having retired, the foreman returned to the Court to ask what was the exact position with regard to the practising of the plaintiff within the area given in the agreement. The Judge held that, if Mr. Draycott had broken the agreement by dismissing plaintiff without sufficient reason, then he could not prevent Illingworth following his calling within the area mentioned in the agreement.

The jury found a verdict for plaintiff, with damages 200*l.*

EXHIBITION OF CANINE PHOTOGRAPHY.

Our contemporary, *The Stock-keeper*, in announcing an Exhibition of Canine Photography at the Agricultural Hall, on February 12, 13, and 14, says: "The remarkable progress which has taken place in photography during the last decade, and the wonderful improvements in the apparatus and appliances that are used in connexion with it, have transformed what was formerly an art almost exclusively in professional hands into one of the most popular pastimes. Photography has become a very useful handmaiden to a number of pursuits and professions, and the scope of its utility to the sportsman in general, and the breeder and exhibitor of dogs in particular, can hardly be over-estimated.

"For the purpose of impressing this fact upon the kennel world, and also with the idea of inducing those interested in dogs to pay greater attention to the proper application of art and correctness of position in canine photographs, we have made arrangements to hold an Exhibition of Canine Photography on the occasion of Cruft's Dog Show, at the Agricultural Hall, on February 12, 13, and 14, in a specially reserved portion of the gallery. The details of the programme are not yet completed, but, to give our readers a general notion of the plan that will be followed, we may mention that the competition will take place in the following classes:—

"Class 1.—The best portrait of a prize-winner.

"Class 2.—The best portrait of the head of a prize-winner enlarged to life size.

"Class 3.—The best photograph of a sporting dog at work.

"Class 4.—The best photograph of a recognised pack of hounds.

"Class 5.—The best photograph of a dog running or jumping.

"Class 6.—The best photograph of one or more dogs in a subject picture.

"Class 7.—The most interesting photograph of a dog from an historical point of view.

"Class 8.—The best photograph of a kennel establishment.

"All the photographs must be taken from life, and in Classes 1, 3, 4, 5, 6, and 8 no exhibit will be admitted of less than cabinet size.

"There will be no entry fee.

"An appropriate number of *The Stock-keeper* silver and bronze medals will be awarded in the various classes, and there will also be a large number of specials offered. Some of them will be for certain breeds in particular. A list of these will be published shortly, but there will be one special which should be of interest to all intending exhibitors at the show, viz :—

"A three-guinea cup (money or plate), offered by Mr. Chas. Cruft for the best photograph of a dog exhibited at the Show.

"Further particulars of *The Stock-keeper* Exhibition will be published in that journal of January 10."

PHOTOGRAPHIC COPYRIGHT UNION.

THE following are the rules as amended at the General Meeting, November 22, 1895.

COMMITTEE.

President, Frank Bishop (Marion & Co.). *Vice-President*, Joseph J. Elliott (Elliott & Fry, Baker-street). *Treasurer*, Wm. Grove (Window & Grove, Baker-street). *Honorary Secretary*, J. Lillie Mitchell (London Stereoscopic Co., Ld.), 54, Cheapside, London, E.C. Wm. Downey (W. & D. Downey, Ebury-street), Alfred Ellis (Upper Baker-street), E. Frith (Frith & Co., Reigate), Jas. Lafayette (Dublin), Louis Wilson (G. W. Wilson & Co., Ld., Aberdeen). *Solicitors*, Messrs. Neish, Howell, & Macfarlane, 66, Watling-street, London, E.C. *Secretary*, Henry Gower, Photographic Section, London Chamber of Commerce, Botolph House, Eastcheap, London, E.C.

TITLE.

I.—The name of the Society shall be the "Photographic Copyright Union."

OBJECTS.

II.—The objects of the Union shall be to secure and protect Photographic Copyrights, to suppress piracies, and generally to promote the interests of the profession.

MEMBERSHIP.

III.—Photographers who have given their signed adherence to the Union shall be considered duly elected, and all professional and amateur photographers and photographic publishers shall be qualified to become Members of the Union under the rules, provided they be introduced by a Member.

IV.—The Committee shall have the power of nominating as Honorary Members, free from any subscription, any persons resident abroad or in the colonies, whom they may in their discretion select as corresponding Agents for the Union.

FUNDS.

V.—There shall be a Donation Fund and a Reserve Fund. The Donation Fund shall be deposited in the name of the Union, and cheques drawn therefrom as per Rule XI. The Reserve Fund shall be deposited at the Bankers in the joint names of the President and Treasurer of the Union, and only in the event of a deficiency in the Donation Fund shall expenses be defrayed out of the Reserve Fund.

VI.—There shall be no Annual Subscription.

VII.—The Working Expenses of the Union shall be met by Voluntary Donations.

RESERVE FUND.

VIII.—A Reserve Fund shall be created, to consist of Voluntary Donations and of such other funds as may be found available for the purpose.

OFFICERS.

IX.—The management of the Union shall be by a Committee of nine Members (but with power to increase their number), two of whom shall retire annually, but shall be eligible for re-election. The Committee shall elect annually from among themselves a President, a Vice-President, and a Treasurer, and the Committee shall be Members of the Photographic Trade Section of the London Chamber of Commerce.

X.—The mode of Election of Members of the Committee shall be by the vote of the General Members of the Union.

XI.—The Bankers of the Union shall be the National Provincial Bank of England, St. Marylebone Branch, Baker-street, W. All cheques shall be signed by the Treasurer, and a Member of the Committee, and countersigned by the Secretary.

XII.—The Standing Counsel, Solicitors, and Secretary of the Union shall be appointed by the Committee, and shall hold office for such time and upon such terms as may be determined by the Committee. No Member of the Committee shall be eligible as Auditor.

MEETINGS OF COMMITTEE.

XIII.—The Committee shall meet monthly on the first Wednesday in each month, but a Meeting may be called by the Secretary, upon the request of any two Members of the Committee. Three clear days at least must elapse between the issue of the notices (unless the Secretary shall mark them "very urgent") and the day for which the Meeting is called.

XIV.—Five shall form a quorum of the Committee, except where otherwise hereinafter provided. Questions arising at any Meeting of the Committee shall be decided by a majority of votes, and, in case of an equality of votes, the Chairman of the Meeting shall, in addition to his original vote, have a casting vote.

ACCOUNTS.

XV.—Proper books of account shall be kept at the offices of the Union, and all such accounts shall be audited by the Auditors once in every year, and oftener if the Committee shall so determine. The Auditors shall be elected by the Members of the Union present at the General Meeting. All moneys received by the Secretary shall be paid to the Treasurer within seven days.

GENERAL MEETINGS.

XVI.—A General Meeting of the Union shall be held in the month of October in each year, and of such Meeting seven days' notice shall be sent to each Member, together with the report (if any) of the Committee, and an abstract or short statement of the accounts of the Union, together with a note of any alterations of and additions to the Rules that may be proposed. Extraordinary General Meetings shall be summoned at any time, upon the requisition of twenty Members of the Union. At any such Meeting the Rules of the Union may be added to or altered by the vote of two-thirds of the Members present, provided that fourteen days, prior notice has been given to the Secretary stating the proposed additions or alterations. Fifteen Members shall form a quorum at such Meetings, and the Chairman shall have a casting vote.

WORK OF THE UNION.

XVII.—The Society will undertake to register the work of any Member who desires them to do so upon the payment of 1*s.* 6*d.*, which is inclusive of the fee of 1*s.* at Stationers' Hall, but the Union shall incur no responsibility in case any such registration shall be held to be defective by any Court of Law.

XVIII.—Any Member shall have the privilege of referring the application of any Publisher or other person, who may desire to copy his works to the Secretary to arrange terms for the same. A record will be kept of all licences and permissions negotiated by the Union, who shall be entitled to charge a commission of ten per cent. on all sums obtained by them in this manner for a Member.

XIX.—Members whose work has been infringed, and who wish the Union to obtain redress for them, must send the Secretary an original photograph, the piracy complained of, a copy of the registration form, the place and date of purchase of the piracy, and the name and address of the person by whom purchased, together with all correspondence that may have any reference to the piracy in question. The Secretary, having satisfied himself and any one Member of the Committee that the essential preliminaries to registration have been duly observed, shall then submit the case to the Solicitor, who will advise the Secretary upon it. A quorum of three of the Committee shall have power to give the Solicitor authority to proceed, but in urgent cases an action may be commenced by the Solicitor, should he deem it advisable, before the Committee have time to sit, but not before obtaining the written authority of the Member or Members interested, and in such cases, until the action of the Solicitor be ratified by three Members of the Committee, the Union shall not be liable for any costs.

XX.—If when a case, at the request of a Member, has been conducted by the Union, and compensation by way of penalties, or damages, or otherwise, be obtained, the net proceeds shall be divisible as follows: Two-thirds shall go to the Member whose copyright has been infringed, and one-third to the Reserve Fund of the Union. If no damages are obtained, then the expenses shall be borne as follows: Fifty per cent. shall be paid to the Union by the Member on whose behalf the action was taken, and thereafter fifty per cent. by the Union.

XXI.—In all cases where the aid of the Union has been invoked, and compensation obtained for a Member without litigation, the Union shall deduct twenty-five per cent. of the amount obtained after deducting expenses, and shall pay the balance to the Member.

XXII.—That the Committee, shall have the power, should they deem it advisable, to give such rewards as they shall agree upon to any one who give such information as shall lead to the conviction of an offender or to successful litigation.

☞ XXIII.—That no Member shall allow a Copyright picture belonging to him to be reproduced (whether registered or not), for a less fee than 10*s.* 6*d.* on each occasion, and for each different publication or form in which it is used, but he shall be at liberty to charge a larger fee according to his own ideas as to its value.

XXIV.—That Members be invited to seek advice and information of the Union through the Secretary, which shall be given free of charge.

XXV.—That the Society will assist Members in assigning Copyrights,

and help them in every possible way in all maters relating to Copyrights.

The following are—

COPIES OF FORMS ISSUED BY THE PHOTOGRAPHIC COPYRIGHT UNION.

[2d. per dozen.—*Prices include Postage.*]

FORM A.]

Photographic Section of the London Chamber of Commerce.

BOTOLPH HOUSE, EASTCHEAP.

Photographic Copyright Union.

In reply to your request for permission to copy my photograph of.....

.....I beg to state that, being a Member of the above Photographic Copyright Union, I am bound by its regulations to make a charge for the permit required. My fee in this case will be .....and on receipt of this amount I will forward you official permission. .....

.....

NOTICE.—Any one copying my photographs for the purposes of reproduction or illustration either in Newspaper, Magazine, Book, or any other form, without first obtaining my permission, render themselves liable to an action for infringement of my copyright.

FORM B.] Receipt granting permission to use Copyright Photographs.

Issued by the Photographic Copyright Union.

.....

.....

.....*day of*.....189...

In consideration of the sum of.....hereby acknowledged, you are authorised to reproduce, by.....process, my Copyright Photograph of.....in any size not exceeding... ..... my name to be printed under each impression.

This Permission and Fee is for reproduction in.....

and for one issue only, and the subject may not be reproduced or sold as an independent illustration separate from the above publication and its accompanying letter-press. If any other use is desired, a fresh Permission and Payment is required. .....

NOTICE.—Any one copying my photographs for the purposes of reproduction or illustration either in Newspaper, Magazine, Book, or any other form, without first obtaining my permission, render themselves liable to an action for infringement of my copyright.

FORM C.] Receipt granting permission to use Copyright Photographs.

Issued by the Photographic Copyright Union.

.....

.....

.....*day of*.....189...

In consideration of the sum of.....hereby acknowledged, you are authorised to reproduce, by.....process, our Copyright Photograph of.....in any size not exceeding..... our name to be printed under each impression.

This Permission and Fee is for reproduction in.....

and for one issue only, and the subject may not be reproduced or sold as an independent illustration separate from the above publication and its accompanying letter-press. If any other use is desired, a fresh Permission and Payment is required. .....

NOTICE.—Any one copying our photographs for the purposes of reproduction or illustration either in Newspaper, Magazine, Book, or any other form, without first obtaining our permission, render themselves liable to an action for infringement of our copyright.

Our Editorial Table.

LETTS'S PHOTOGRAPHER'S POCKET DIARY FOR 1896.

London: Charles Letts & Co.

THIS is a neatly got-up little diary, in which a great deal of tabular matter, practical hints, and information likely to be of use to amateur photographers has been incorporated. Plenty of space is given for recording particulars of exposures, but not enough, we think, for the diary pure and simple, sixteen days being provided for within the space occupied by a quarter-plate. Apart from this, however, it is a useful and handy book. It contains a directory of hotels, photographic dealers, and cycle-repairers. The editor of the diary, Mr E. J. Wall, has done his work extremely well.

RECENTLY ELECTED OFFICERS OF SOCIETIES.

(*Received too late for the* ALMANAC.)

AMATEUR PHOTOGRAPHIC ASSOCIATION OF VICTORIA.—Established 1893. Meetings held at the Royal Society's Rooms, Melbourne. *President*: Mr. E. A. Walker.—*Vice Presidents*: Dr. J. C. Kaufmann and Mr. Edgar C. Bell.—*Committee*: Messrs. W. Farquaar, G. H. Heather, J. H. Mulvany, D. W. Paterson, H. Small, H. C. Ward, C. W. Watts, and E. Wood.—*Treasurer*: Mr. F. W. Miscamble.—*Secretary*: Mr. J. H. Harvey, 127, Gipps-street East, Melbourne, Australia.

AVON VALE PHOTOGRAPHIC SOCIETY.—Meetings held at Elmhurst, Batheaston, Bath, first Tuesday each month. *President*: Colonel Sealy.—*Committee*: Messrs. W. M. Ashman, C. Ward, W. Hinds, Rev. E. A. Pervis, and Messrs. J. W. Hooper, J. Weston, and H. Stratton Coles.—*Secretary and Treasurer*: Mr. W. H. Crossman, Kelston Villa, Batheaston, Bath.

FINSBURY TECHNICAL COLLEGE PHOTOGRAPHIC SOCIETY.—The meetings are held at five o'clock on Wednesdays once a fortnight. *Patrons*: Sir Philip Magnus, B.A., B.Sc., and Messrs. J. Perry, M.E., D.Sc., F.R.S., A. P. Brophy, and S. P. Thompson, D., Sc., F.R.S.—*President*: Mr. R. Meldola, F.R.S., F.I.C., F.C.S.—*Vice-Presidents*: Messrs. J. Castill-Evans, F.I.C., F.C.S., and E. Thomas, B.Sc.—*Committee*: Messrs. J. C. Tell, F.C.S., F. W. Bunyan, Powell, and L. H. Andrews.—*Hon. Treasurer*: Mr. T. H. Norris, A.J.C.—*Hon. Secretaries*: F. R. H. Wood and H. F. E. Hulton.

GORDON COLLEGE AMATEUR PHOTOGRAPHIC ASSOCIATION.—Established 1889. Meetings held at Gordon College, Geelong. *Patron*: Mr. Phillip Russell.—*President*: Mr. H. G. Roebuck.—*Vice-Presidents*: Messrs. J. B. Leitch and G. H. Brinsmead.—*Committee*: Messrs. C. O. Dentry, A. Furnell, J. F. Miller, A. E. Brathley, and W. M. Waddell.—*Treasurer*: Mr. W. H. Thacker.—*Secretary*: Mr. John Hammerton, jun., 73, Little Ryrie-street, Geelong, Victoria.

HANDSWORTH PHOTOGRAPHIC SOCIETY.—Meetings are held at Headquarters, second floor, College House, Hamstead-road, Handsworth, and not at 18, Albert-road, Handsworth, as given in ALMANAC.

KENT POSTAL CAMERA CLUB.—Formed 1895, consisting of fifteen members, having a portfolio and note-book in monthly circulation. *Hon. Secretary*: Mr. A. P. FORD.

LENS, SUN, & COMPANY POSTAL PHOTOGRAPHIC CLUB.—Limited to twelve members. Circulates monthly folios, in which the members criticise each other's pictures. Occasional articles on photographic subjects are written by the members. *Hon. Secretary*: Mr. Ward Muir, 4, Victoria-road, Waterloo, Liverpool.

LLANDUDNO CAMERA CLUB AND LANTERN SOCIETY.—Established 1892. Meetings held at Club House, Bodhyfryd-road, Llandudno (near Post Office). *President*: Right Hon. Lord Mostyn.—*Vice-Presidents*: Dr. Dalton, J.P., and Messrs. A. H. Hughes and Elias Jones, J.P.—*Committee*: Messrs. Ashby, Campbell, Eccles, Jones, Watterson.—*Treasurer*: Mr. W. Williams.—*Secretary*: Ernest Deacon, Gladdaeth-street, Llandudno.

OLDHAM PHOTOGRAPHIC SOCIETY.—*President*: Mr. James Brooks.—*Vice-President*: Mr. John Chadwick.—*Committee*: Messrs. J. Greaves, jun., C. A. Hempstock, T. Heywood, James Hall, B. J. Holt, and W. A. Nash.—*Librarian*: Mr. John W. Cooper.—*Treasurer*: Mr. J. Hilton Ashton.—*Hon. Secretary*: Mr. Thomas Widdop, 17, Queen-street, Oldham.—*Assistant Secretary*: Fred Megson.

STAFFORD Y.M.C.A. AMATEUR PHOTOGRAPHIC SOCIETY.—Established 1895. Meetings every alternate Monday in the Y.M.C.A. rooms. *President*: Mr. H. Cliff.—*Vice-President*: Mr. F. Fowke.—*Committee*: Messrs. M. Averill, W. Kirkham, W. H. Rostance, R. Hourd, and C. J. Flint.—*Hon. Secretary* and *Treasurer*: Mr. F. Cliff, 11, Gaol Gate-street, Stafford.

WELLINGTON CAMERA CLUB.—Established 1892. Meetings held at Academy of Fine Arts. *President*: Mr. A. de B. Brandon.—*Vice-Presidents*: Messrs. A. McKay and J. McLellan.—*Committee*: Messrs. G. Crichton, E. H. Freeman, T. M. Hardy, A. B. Keyworth, T. Pringle, and William C. Stephens.—*Treasurer*: Mr. T. M. Hardy.—*Secretary*: Mr. Frank J. Denton, 33, Willis-street.

News and Notes.

ROYAL PHOTOGRAPHIC SOCIETY.—Ordinary Meeting, Tuesday, January 14, at 8 p.m., at 12, Hanover-square, W. *Astigmatism and a new Astigmatic Portrait Lens*, by Mr. H. L. Aldis, B.A. (Cantab.).

THE WATKINS DEVELOPING COMPETITION AT THE PHOTOGRAPHIC CLUB.—We are informed that the Judges in this Competition have awarded the first prize of 4*l.* 4*s.* to Mr. B. J. Edwards, and the second prize of 2*l.* 2*s.* to Mr. B. E. Edwards.

THE PHOTOGRAPHIC CLUB.—The next weekly meeting of the Club will be held in the Club-room at Anderton's Hotel, Fleet-street, E.C., at eight o'clock on Wednesday evening, January 15. Mr. J. S. Sunderland (Messrs. Newnes & Co., Limited) will read a paper on *The Engraving and Printing of Half-tone Blocks*, illustrated with examples. Visitors are always welcomed by the members.

Mr J. W. Waterhouse, R.A., has lately been experimenting in lithography, and we understaud that a drawiug made by him specially for the *Studio* will be given away as a supplement with the mid-January number of that publication.

A Screen for Photo-mechanical Printing.—Mr. Edouard G. D. Deville, of Ottawa, Canada, in order to change the continuous tones of an original into tones formed of black and white dots by a screen placed in front of the photographic plate, has devised a new kind of screen, furnished with alternate opaque and transparent squares, disposed like the squares of a chessboard.

Messrs. Fuerst Brothers, of 17, Philpot-lane, E.C., write: "It may interest you to know that we have appointed Mr. T. Donald Watson (for over thirty years with Messrs. Johnson's, Cross-street, Finsbury, E.C.) to manage our Photographic Department, aud he will devote special attention to nitrate of silver, chloride of gold, developers, and all other photographic chemicals."

The *Photographic Times* Publishing Association, of New York, write: "Having noticed it stated in an English contemporary that the *Photographic Times*, owing to copyright complications, is no longer obtainable in England, we ask you to be kind enough to publish the fact that such is not the case. While it is true that we no longer have au authorised English agent, yet we are opan to receive subscriptions from any country. As a special inducement to English subscribers, we make no extra charge for postage, and intend in future mailing the magazine, wrapped in such a manner that it will reach distant subscribers in good condition."

Patent News.

The following applications for Patents were made between December 23 and 31, 1895:—

Lanterns,—24,560. "An Improved Method of and Apparatus for Exhibiting Pictures by means of an Optical Lantern or otherwise, parts thereof being applicable for other analogous purposes." W. J. Spurrier.

Printing Plates.—24,593. "Improvements in Photographic Printing Plates." G. Poore.

Lenses.—24,641. "Improvements in Photographic Lenses." T. R. Dallmeyer.

Apparatus.—24,737. "Improvements in Photographic Apparatus." Communicated by Auguste Tournier, France. B. J. B. Mills.

Cameras and Dark Slides.—24,886. "Improvements in Photographic Apparatus or Cameras for Amateurs, and in the Plate Receptacles connected therewith." I. de Balás.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

January.	Name of Society.	Subject.
13.....	Camera Club	*Optics and Lenses.* Lyonel Clark.
13.....	Richmond	*The Speed of a Plate.* R. Child Bayley.
14.....	Brixton and Clapham	*Lantern-slide Making.* E. Dockree.
14.....	East London	*Platino-bromide Paper, &c.* Nahum Luboshez.
14.....	Royal Photographic Society ...	*Actigmatism and a New "Stigmatic" Portrait Lens.* H. L. Aldis, B.A. (Cantab.).
15.....	Croydon Camera Club	Lantern Night for Members' Slides.
15.....	Croydon Microscopical	Visit to Brin's Oxygen Works.
15.....	Leytonstone	Demonstration on the Platinotype Printing Process. T. H. Stringer.
15.....	Photographic Club	*The Engraving and Printing of Half-tone Blocks.* J. S. Sunderland.
16.....	Bradford	*Home Portraiture.* T. C. Bridges.
16.....	Camera Club	Views in the Himalayas, with *Notes on the Photographic Needs of Mountain Explorers.* Sir W. Martin Conway.
16.....	Darwen	Smoking Concert.
16.....	Leeds Camera Club.....	*The Optical Lantern and its Use.* A. Bourke.
16.....	Leigh	*Copying.* T. Haddock.
16.....	Liverpool Amateur.....	Demonstration on Bromide Printing. F. Anyon.
16	Oldham	Enlarging. The Members.
17.....	Birkenhead Photo. Asso.	*Retouching.* Mr. Walton.
17.....	Croydon Microscopical	Slides of Alpine Scenery. Captain W. de W. Abney, C.B., &c.
17.....	Southport	Lantern Slides.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

January 2,—Mr. A. Haddon in the chair.

The Hon. Secretary showed the result of a further trial of the Cooke lens at *f*-45 without the mask, whereby the field was increased by about an inch.

Stereoscopy on the Screen.

Mr. T. E. Freshwater then read a paper on *A Simple Method of Projecting Stereoscopic Pictures on the Screen by means of Two Ordinary Lanterns.* [See page 24.]

Mr. R. P. Drage asked if the density of the coloured glasses could be lessened?

Mr. T. E. Freshwater answered that the screen should be of such a colour value that when you look at the picture through the green glass, closing one eye, you should only see a green picture, and so with the red. Thinking it possible that he could get a little more light by the use of some reds of a shade lighter tint, he had tried the experiment, but found they were quite useless.

The Chairman said, Why go to the expense and trouble of binding each pair of slides with different colours, when by putting two pieces of glass only, suitably worked, on the hood of the lens, one could do away with all that. He thought that the two images should be brought as nearly as possible to registration on the screen, as, when there was much lateral separation, a peculiar and disagreeable sensation was caused in the eye.

Mr. T. Bedding asked as to the possibility of using one lantern only.

Mr. Freshwater replied that the superposition of the two colours would stop too much of the light.

Mr. W. E. Debenham asked for the opinions of those present as to why, when the head was shifted, the distant objects appeared to move in a contrary direction to the head, and gave his opinion.

A visitor said that, on looking at the screen without the eyepieces, the picture appeared to be double the size as when viewed through the spectacles, and inquired whether it was a defect in his eyesight.

Several others present noticed the same peculiarity.

Mr. Freshwater thought that when viewed stereoscopically, the pictures lengthened out and so appeared to be smaller.

The Hon. Secretary thought that the glasses used in showing certain of the slides were of a deeper tint than the others, but this was contradicted by Mr. Freshwater.

Mr. Debenham said the fact that some people's eyes were more sensitive to the red, and some to the blue, would probably explain the apparent difference in the glasses.

Mr. Freshwater admitted that the tints of the reds might vary somewhat, but the blue were all of a kind.

Mr. Haddon repeated that, with properly worked glass, he could see no reason why the screens should not be attached to the hood of the lens.

Mr. J. B. Spurge mentioned that at a Mr. Crowther's request he had experimented in the same way, and with the same success, excepting the want of light in the picture. He also briefly described another variation by which he obtained a good stereoscopic effect without loss of light.

PHOTOGRAPHIC CLUB.

January 1,—Mr. E. W. Foxlee in the chair.

The report of the Judges in the Watkins Competition was made verbally to the meeting. This, and a report of the discussion which ensued, will be published next week.

Brixton and Clapham Camera Club.—December 31, Mr. J. W. Coade (President) in the chair.

Experiments with Light

was the subject treated of by Mr. J. C. Osborne in a manner which proved both interesting and instructive. Commencing with a mention of the now generally recognised undulatory theory of light transmission, he explained, by means of diagrams and numerous practical experiments, various points connected with the phenomena of light-absorption, transmission, and reflection by plane surfaces, the refraction of light by passing through mediums of varying densities, and the inversion of the image as seen on the focussing screen of a camera. The analysis of white light was shown by placing a prism in the beam of light projected by the limelight lantern, and variations in the spectrum, produced by burning foreign bodies, as copper foil and phosphorus, in the lantern flame. Colour formation was also touched upon, and the dependence of a substance, whether liquid or solid, for its colour upon its chemical composition was exemplified by a number of characteristic chemical reactions, *i.e.*, the familiar one of adding to a solution of silver nitrate an equally colourless solution of sodium chloride, thus producing a white precipitate of silver chloride. The relation of light to energy was shown by the radiometer, and the chemical effects of light are so well known to photographers as to require no illustration. Perhaps the most useful part of the demonstration, however, consisted in the spectroscopic examination of different samples of ruby and orange glass used for developing lamps, proving it quite possible to so illuminate the dark room as to allow development to be comfortably watched, and, at the same time, without risk of fogging even the most sensitive plates, provided a suitable medium is chosen. So important was this part of the demonstration considered, that it is proposed to add a prism to the Club apparatus, thus affording members an opportunity of testing their own medium as required. The demonstration concluded with the production of an artificial rainbow. By forcing water under a pressure of 200 pounds per square inch through a small orifice, it issues in a very finely divided state, and the rays of the lantern shining on the spray thus produced forms upon the screen the colours of the spectrum. A vote of thanks was awarded to Mr. Osborne for this, his first demonstration, after which the discussion upon the subject, the election of three new members, and the nomination of officers for 1896 brought to a close a successful and somewhat lengthy meeting.

Croydon Camera Club.—The meeting on New Year's Day was the first of a series of "Novices' Nights," intended to show beginners the way in various photographic walks. The subject,

How to Make a Lantern Slide,

was handled in a thoroughly practical and complete manner by Mr. A. E. Isaac, than whom it would be hard to discover a more capable or reliable

gnide. His demonstrations and remarks not only informed the tyro, but included much that some of the old hands present were glad to make a note of. At the conclusion the large gathering gave Mr. Isaac a flattering vote of thanks. Amongst many other prints shown during the evening, notable were several exhibited by Mr. J. Noaks. These were on gelatino-chloride paper, and had been printed by means of an ordinary incandescent gas burner, using mantle C, the time taken being within two hours. The practical importance of this proof of the availability of the above light can only be gauged by those having to deliver silver prints at this time of the year. In some instances a fitful daylight has not been sufficient to obtain one print. Mr. Noaks estimated that, by exposing a number at once, an incandescent burner would print about twenty to twenty-five cabinets a day, and the cost would be nominal. Mr. H. T. Thornton was elected a member.

Woodford Photographic Society.—January 2, Mr. E. B. Caird in the chair.—Mr. Marriage showed a lantern slide developed with saccharate of lime; he spoke of it as being a very rapid developer. The Chairman showed some Eastman films of snap-shots exposed in August 1893, and only just developed. Two or three gave very good results, but two or three others exhibited marks evidently caused by pressure of elastic bands used in packing the films after exposure. It was decided to apply to the Royal Photographic Society for the loan of a set of lantern slides and Mr. Warnerke's paper on the development of printing-out papers.

Bradford Photographic Society.—A new venture was attempted by the above Society on Thursday, January 2, in the shape of a ladies' and children's night, which proved to be a remarkable success. The proceedings took the form of a dioramic entertainment kindly provided by Messrs. R. J. Appleton & Co., of Manningham-lane, who put forth every effort, and spared neither time nor expense to make the evening enjoyable for all. Mr. Appleton himself manipulated his magnificent triple lantern, and rejected many hundred charming views, comic moving fairy tales, and others upon the screen, to the delight of over 300 members, lady friends, and children. At short intervals songs were rendered by Miss Lily Ellison and Master Harry Berry, and humorous recitals by Mr. Alex. Keighley and Mr. E. H. Scales. A hearty vote of thanks was accorded to Mr. R. J. Appleton and his staff, and all who had contributed for their kindness in providing such a splendid evening's enjoyment. A box of sweets was handed to each child, with the compliments of the Bradford Photographic Society. It is to be hoped that a night similar to this may be indulged in once every season.

Leeds Camera Club.—The Judges' reports and criticisms on prints handed in for the Leeds Camera Club 1895 Competitions were read at the fortnightly meeting of this Society on Thursday evening last. The total number of competitors in the various classes was twenty, several of whom had entered for two or more subjects. An analysis of the competitions shows that sixteen members sent 102 prints in the Landscape Section; 32 prints were submitted by twelve competitors in the Architectural Class; 21 by seven members in Portraiture; and 20 by three members in the Snap-shot Division. Mr. Alex. Keighley (the President of the Bradford Photographic Society) judged the landscape photographs, and the Rev. Mr. Addison (President of the Wakefield Photographic Society) acted in a similar capacity in the remaining classes. The Judges' criticisms upon the work submitted, individually and collectively, were much appreciated, and the valuable hints they kindly tendered will, doubtless, be acted upon, and be evinced by a higher standard of work in future competitions. The prizes were awarded as follows:—Landscape: (1) silver medal and certificate, A. Gaunt; (2) bronze medal and certificate, W. R. Irwin; (3) certificate, G. Roberts. Architecture: (1) silver medal, A Homburg; (2) bronze medal, J. Sedman; (3) certificate, W. Bottom. Portraiture: silver medal, E. C. Oddy. The awards in the Snap-shot were withheld, there being insufficient competitors. The Rev. Mr. Addison, who personally read his report, afterwards kindly criticised a large number of members' lantern slides, which were exhibited on the screen. It has been found necessary to postpone Mr. J. W. Garbutt's lecture on *Wet-collodion Lantern Slides*, announced for January 16, and Mr. Bourke has undertaken to fill that date with a practical demonstration on *The Optical Lantern and its Use.*

FORTHCOMING EXHIBITIONS.

1896.

February 27-29 ..... Woolwich Photographic Society.

March 2-6 ..... *South London Photographic Society. Hon. Secretary, Charles H. Oakden, 30, Henslowe-road, East Dulwich, S.E.

" 3-6 ..... *Cheltenham Amateur Photographic Society. Philip Thomas, College Pharmacy, Cheltenham.

* Signifies that there are Open Classes.

Correspondence.

☛ *Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

GRAINED NEGATIVES.

To the EDITORS

GENTLEMEN,—As there seems to be a difference of opinion as to the cause of dots spreading in making grained negatives for process work, I should like, with your permission, to state my views of the question, in the hope of eliciting the truth from some of your scientific readers

I believe it is said that the enlargement of dots is not caused by diffraction, but by the light reflected from a considerable area of the original subject acting through one opening in the screen (in fact, by lateral action). I think this to be a mistaken idea, for, in my opinion, each screen opening only allows that light to pass which is projected normally from the point corresponding to it in the original; and the size of dot I consider to be ruled, partly by exposure, partly by development and intensification, and partly by diffraction, which varies much with the distance between the screen and the plate, besides chemical actions. Apologising for troubling you with such an uninteresting subject,—I am, yours, &c, J. A. C. BRANFILL.

25, *Rosendale-road, West Dulwich, S.E., January* 6, 1896.

HEAT AND TONE.

To the EDITORS.

GENTLEMEN,—The effect of heat upon the colour of some photographic prints, described by Mr. Blunt in your last issue, will not be new to most professionals.

It is, of course, well known that, after passing a silver or gelatine print through the burnisher or hot roller, the tone is almost always altered to a shade or so warmer, the degree depending upon the heat of the burnisher, and also upon the brand of paper. I recollect passing a print on collodio-chloride paper, which had been carried as near black as is possible with the sulphocyanide bath, through a very hot burnisher, from which it emerged a brilliant maroon colour. It was, of course, blistered.

To alter the colour of a silver print materially, it is necessary that the burnisher should be very hot, so much so that the print will be covered with blisters, and the only way of avoiding this is to burnish the prints at the usual temperature some time previously, which appears to have the effect of hardening them.

I do not know what the chemical explanation of the change is, but, so far as observation goes, the colour of prints whose tones have been modified by heat are quite as permanent as that of those which have never been rolled.—I am, yours, &c., R. WELLBYE.

Sandycombe, Kew-gardens, S.W., January 4, 1896.

POISONING BY SULPHOCYANIDE.

To the EDITORS.

GENTLEMEN,—If I may trespass on your space a little, I should like to give a warning to those who may think they are impervious against the many modern solutions, as Mr. J. Pike calls them in his article of the 20th inst. I read his article whilst suffering from blood-poisoning in my right arm, caused through knocking a piece of flesh off the knuckle of my little finger, and then, immediately after, toning a large batch of prints in the sulphocyanide bath. I have been in the profession for nearly twenty years, and nothing has ever affected me before; but, as Mr. Pike says, your time will come, and mine has, for it kept me away from business five weeks, which means a considerable loss at the Christmas season.

Hoping this may be just an example to prevent others doing likewise, apologising for taking so much space, and wishing your paper every success for the coming year, I am, yours, &c., F. W. TASSELL.

West Hill Drive, Mansfield, December 31, 1895.

To tone a carbon transparency to a rich black, first immerse it in a weak —say a one per cent—solution of the perchloride of iron until the film is thoroughly permeated, then well rinse under the tap, and afterwards flood the plate with a two grain solution of gallic acid, and keep on till the desired tone is obtained. A great variation in black tones may be made by substituting other salts of iron for the one named, and, instead of using gallic acid, employing a solution of tannin, or a decoction of gall nuts, or one of logwood, &c. These latter agents yield more purple blacks than the gallic acid. In the event of the tones not turning out those desired, the colour can be quickly removed by flowing the plate over with a very weak solution of hydrochloric acid—thirty minims to the ounce of water. Then, after washing out the acid, the toning can be repeated with any of the other substances named.

If we require a greenish blue colour, to give a moonlight effect, we immerse the transparency in a dilute solution of protosulphate of iron, and, after rinsing, pour over it a solution of ferrocyanide of potassium. Prussian blue will be found in the film. A yellow, suitable for sunset effects, is obtained by first treating the slide with a solution of bichromate of potash followed by one of acetate of lead, chrome yellow resulting. A bright red colour is produced when the transparency is first treated with a solution of bichloride of mercury, and, afterwards, with one of iodide of potassium. It will now be seen that the "toning" of carbon transparencies is precisely analogous to the dyeing of fabrics, so that any colour obtainable by double decomposition can be secured in a carbon transparency. As there is no gelatine in the high lights to be dyed, they remain clear and free from colour.—E. W. FOXLEE *in* "*Autotype Notes.*"

Answers to Correspondents.

*** *All matters intended for the text portion of this* JOURNAL, *including queries, must be addressed to* "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 2, *York-street, Covent Garden, London. Inattention to this ensures delay.*

*** *Communications relating to Advertisements and general business affairs should be addressed to Messrs.* HENRY GREENWOOD & Co., 2, *York-street, Covent Garden, London.*

PHOTOGRAPH REGISTERED:—

Mr. G. B. Cowen, Ramsey, Isle of Man.—*Photograph of junction of two lanes, with children blackberrying, at Elgin Glen, near Ramsey, Isle of Man.*

LENSES.—F·8. The lenses of the three makers named have excellent reputations for good qualities.

FINISHING.—R. FORTUNE. We know nothing of the work, neither have we seen a specimen. Why not write to the advertiser for one, or ask for particulars?

TAYLOR'S EXPOSURE TABLES.—EXPOSURE. Refer to the JOURNAL of August 23 last, in which the author of the table has an explanatory article. If this does not assist you, write again.

DEVELOPING.—C. M. BASTOW. To obtain density with eikonogen, allow plenty of time. Allow the negative to attain a greater density in the developer than appears necessary with pyrogallic acid.

ROUGH PAPER.—C. READER. Whatman's rough drawing-paper, such as is used in rough-paper photographs, may be obtained from any of the artists' colourmen, such as Newman's, Rowney's, Winsor & Newton, &c.

PHOTOCHROMS.—R. L. S. says: "Can you inform me of the names and addresses of English firms who do the colour printing—such as those views done in Switzerland, now in shop windows?"—In reply: The address is the Photochrome Co., 61-63, Ludgate-hill, E.C.

SUBSTRATUM.—COLLODION. Take the white of one egg and remove the germ, put it into a large bottle with a quart of water and a few drops of ammonia. Add some broken glass and shake up for a few minutes, then filter for use. It may be flowed over the glass while it is wet.

TONING.—T. SAWYER. The mealiness in the prints is due to the bath being used directly it was mixed. The proportions—thirty grains of acetate of soda; water, eight ounces; chloride of gold, one grain—is quite correct; but the solution should be made at least twenty-four hours before it is used.

DRY COLLODION.—P. C. FREWIN. We do not see how you could well fail with the process as given, unless too much of the silver was washed out of the film before the albumen was applied. The collodion should be of a very porous nature for this process, and the development conducted with acid pyro and silver.

RETOUCHING.—S. OSBORNE. The fault with the retouching on the negative sent is twofold. First, far too thick a coating of the medium was applied in the first instance; second, too soft a pencil was used for the work. B and HB grades are seldom used, except in extreme cases. H, HH, and HHH are those most generally employed.

RESIDUES.—WASTE says: "I am purposing inserting pipes in my developing and toning sinks to take away the old fixing from one, and silver washing from the other. Can you recommend the sort of piping for this? The casks to hold the waste will be some four or five feet away."—Plumbers' ordinary lead pipe will do as well as anything.

PRINTING.—The faults in the print forwarded is that they are over-toned. The primary fault, however, is in the negatives. They are far too weak to give prints that will bear toning much beyond the red stage. No toning bath will yield purple tones with such thin negatives to print from. The negative has as much to do with the tones as the toning bath.

PANORAMIC CAMERA.—A. A. P. writes: "If A. Dixon requires one of the old clockwork pantoscopic cameras for taking panoramas of 180° on a flat 7½ × 4½ plate, I believe Miss Johnson, Photographer, Dodsworth's-court, Briggate, Leeds, has one of the original ones. The price was about 15*l.* to 20*l.* If she has it yet, it might require cleaning up, but she would sell it cheap."

ENLARGING.—M. T. SMITH says: "I have a lantern by ——, and the other night I tried to make some enlargements with it. Although the image was focussed sharply, the enlargements, one and all, were miserably out of focus when developed. Can you explain?"—Yes. The optical and chemical foci of the objective do not coincide. This is the case with the objectives of many lanterns, and it is of no disadvantage for projection purposes alone; indeed, it is rather an advantage that they do not.

YELLOW SCREENS.—MR. R. SMITH says: "I shall be glad if you will give me the formula for a screen that will cut off the violet and ultra-violet rays, so that I can successfully use it with an ordinary plate in photo-micrography. Mr. Ives mentions such a screen in THE BRITISH JOURNAL OF PHOTOGRAPHY, but does not give the formula; if he has such a screen for sale, I shall be glad to buy."—In reply: Possibly some of our readers, or Mr. Ives, will give the desired information.

STRIPPING NEGATIVES.—B. T. The negatives should be alumed before they are stripped, then they will not expand to any great extent. If there should be any expansion at all, the film may be reduced to its original size by immersing it in alcohol. Instead of using sulphuric acid, employ hydrofluoric in the proportion of a few drops to the ounce of water. Cut round the figure while it is on the glass before stripping, then float it into the position it is to occupy in the other negative which has been prepared to receive it.

PRINTING.—F. M. asks: "Could you advise us how to prevent printing-out paper from sticking to the negative if left in the frame over night? The recent damp weather has caused us a lot of trouble, living as we do near the seaside."—If the paper, negative, and the pads are made perfectly dry when they are put in the frame, there will be no sticking. When the prints are left in the frame all night, the latter should be stored in a dry place.

COLLOTYPE.—W. S. G. writes as follows: "Can you tell me where I can obtain plates prepared for collotype, *i.e.*, ready for exposure; or, if not ready-sensitised, that can be sensitised by the user? I have looked through several numbers of the JOURNAL and the advertisements in the ALMANAC, but can get no information."—The plates are not articles of commerce, and for this reason they must be used within a day or two of their being prepared, as they will not keep, and they are always made in the sensitive state by those who use them.

TONING.—J. says: "The toning bath for Eastman's Solio paper is about forty grains of sodium acetate and about three grains of ammonium sulphocyanide to a grain of gold. I think this is near the proportions. Will you please say if a good bath can be made without the soda, and should the sulphocyanide be increased? I have a friend who appears to have only two solutions, viz., gold and sulphocyanide, and mixes just before use in cold water."—A toning bath may be made which answers well with some papers; it is made in the proportion of fifteen grains of the sulphocyanide to one grain of the chloride of gold; but whether it will work well with the paper named we cannot say, as we have never tried it.

CAMERA OBSCURA.—R. H. writes as follows: "On page 533 of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC for 1896 there is an article on *Photographers as Draughtsmen*, and a description of a portable camera obscura. Will you be good enough to inform me: 1. In which number of your JOURNAL the article originally appeared? 2. What should be the diameter of the lens of fifteen-inch focus, and the diameter of the diaphragm? 3. What sized picture will a lens of this focus give?"—In reply: 1. June 28, 1895. 2. Any photographic lens that you may happen to possess worked with its full aperture, or a single non-achromatic lens may be used for the purpose with a stop of about *f*·10. 3. According to the form of lens. One of the rapid type, about twelve by ten inches; a single lens, about ten by eight.

GREASE.—R. G. W. says: "A careless assistant in the mounting room has got two or three drops of sweet oil on a finished enlargement on bromide paper. The spots are not on the face but on the drapery, but they quite spoil the picture. Unless I can get them out I shall have to get another done at a cost of something like thirty shillings. In the event of the picture being ruined past restoring, can I legally stop its cost from the girl's wages?"—We answer the latter query first by saying No, unless the damage was wilfully done. The picture can, however, be repaired. Take some pure benzole and apply a little to the grease spots, and, in a few seconds, blot off with clean blotting-paper. Repeat this treatment until the grease is entirely removed. The benzole must be the best, or it may leave a stain.

FOGGED PLATES; INTENSIFICATION.—G. B. says: "1. A little time ago I bought a hand camera which I believe is quite light-tight, and yet all the plates fog with the shortest exposure, soon after development is commenced. How is this? Is the aperture of lens too large? I put a piece of ground glass in the camera, and focus the picture, which seems brilliant enough, I then put a plate in, and come straight out of the dark room and expose at once, even keep the camera wrapped up to make sure. 2. Ought negatives (which have been fixed) to be intensified in the dark room, or in the daylight? And what is the cause of a heavy veil all over, making them so dense; I cannot get a print in sunshine in less than a day?" In reply: 1. Difficult to assign the cause on the few details given. Have you ascertained that the light of your dark room is safe? This may be the source of the trouble. 2. Intensification may be conducted in daylight. You appear to have over-intensified.

COLOURED FLAMES; FINDERS; OIL LAMPS.—ALPHA says: "I will feel obliged if you could give me—1. The names of any salts or chemicals soluble in alcohol, so as to give a red flame, a blue flame, and a yellow flame separately. 2. What is the arrangement of lenses in the new Brilliant finder, such as is advertised by Adams? Is it an object glass of a double convex, a mirror and a double convex for eyepiece? 3. Is Mr. Hay Taylor, who edited the *Optical Lantern Journal*, a son of the late Mr. J. Traill Taylor? 4. Do you consider the Pumphrey lamp No. 1, or Stock's No. 2, or the ordinary four-wick, with W-shaped burner No. 3, the most powerful light? Is there anything better in the market for oil?"—In reply: 1. Possibly some of our readers will give the desired information. 2. We have not examined the finder. Ask Messrs. Adams & Co. 3. Yes. 4. You have probably mentioned as good oil lamps as there are, but it is opposed to our rules to make the kind of comparisons you invite.

SMALL LANTERNS.—S. L. S. says: "In looking over some old cuttings from your paper, I came across the following in the report of a lecture by Mr. W. I. Chadwick, on *Small Lanterns and Dissolving Views*. He says: 'The practicability of reducing the size and diminishing the weight of magic lanterns occupied my attention many years ago.' In the BRITISH JOURNAL OF PHOTOGRAPHY, of May, 1878, I published a description, with illustrations, of two small lanterns which I had constructed. The illustrations and descriptions were republished in the *Magic Lantern Manual* of the same year. This appeared about October 28, 1892. Can you give me the *exact* reference of this description, or if the number is out of print? Can you tell me anything about the *Magic Lantern Manual* of that year; whether it is possible to obtain it and where?" In reply: The number referred to is out of print. The *Magic Lantern Manual* may possibly be obtained of Messrs. Warne & Company, Bedford-street, W.C., or of the author, Mr. W. I. Chadwick, 2 St. Mary's-street, Manchester.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 1863. Vol. XLIII.—JANUARY 17, 1896.

Contents.

EX CATHEDRÂ.

On Monday afternoon, a meeting convened by the Electrotypers, Stereotypers, Process, and General Engravers' Associations was held at Anderton's Hotel, the main object of which was to consider the present "cutting of prices" by process-block makers, with the view of providing a remedy for the existing state of things, which is admitted throughout the trade to be an undesirable one. Out of fifty-eight London firms of process-block makers, forty-six were represented at the meeting. It is a pity such a meeting was not held a year or two ago. Our readers are aware that we have, from time to time, commented on the severe competition in process-block makers' charges, and have urged them to come to some common understanding with regard to an agreed scale.

* * *

A long, earnest, business-like discussion took place in which, besides Mr. Boutall, the Chairman (who very ably conducted the proceedings), Mr. Carl Hentschel, Mr. Fuchs, Mr. Cameron Swan, Mr. P. H. Waterlow, Mr. D. S. Dallas, Mr. L. E. Clift, Mr. Wilson, Mr. Swain, and other process-block makers took part, the feeling of the meeting being distinctly in favour of agreed minimum prices for line work on zinc, and half-tone work on zinc and copper. The upshot of the discussion was the carriage of a resolution, binding those present to state by ballot their views as to what those prices should be, the intention being to subsequently ascertain the average of the prices mentioned. Probably it will be found that the prices will come out something like $3\frac{1}{2}d.$ per inch for line work, with a 3*s.* 6*d.* minimum; and 9*d.* and 9*s.* for half-tone blocks.

* * *

We sincerely congratulate the process-block makers on their virtual unanimity in the desire to kill the insane cutting of prices that has recently prevailed among them, and we hope that they will not only come to some agreement in the matter, but will individually keep to it. At the meeting it was mentioned that $1\frac{1}{4}d.$ per square inch for line work, and $3\frac{1}{2}d.$ per square inch for half-tone work were now quoted—absurdly low prices, as was pointed out. The example set by the process men is an excellent one that we commend to portrait and other photographers as eminently worth imitating and profiting by.

* * *

The Transvaal crisis has elicited the fact that Messrs. G. W. Wilson & Co., the well-known photographers of Aberdeen, possess a fine collection of views of Cape Colony, Natal, Zululand, and the Transvaal that were specially taken for them some years ago. Dr. Jameson's unfortunate *faux pas* has turned the eyes of the world towards Johannesburg and Pretoria, which, judging by Messrs. Wilson's photographs, appear to be handsome places. Doubtless, Messrs. Wilson have recently found a brisk demand spring up for all their South African photographs, with, perhaps, the exception of the Majuba Hill series.

* * *

The Hon. Secretary of the Brixton and Clapham Camera Club, Brixton Hall, Acre-lane, Brixton, S.W., writes us: "You will be materially adding to the obligations this Club is under to yourself by sparing us, if at all possible, a line or two in next week's issue to call the attention of your readers to the fact that at Brixton Hall, on Tuesday, the 21st inst., at eight p.m., Mr. A. Ernest Smith, F.R.P.S. (Chief of the Autogravure Department of the Autotype Company, and winner of the Society of Arts' Prize recently offered for photogravure), will

lecture and demonstrate that process, and that we shall, on that occasion, be very pleased to have the company of any one interested."

* * *

We are very pleased to give prominence to the announcement of Mr. A. Ernest Smith's lecture. He is a master of the beautiful process of photogravure, and we hope that he and the Brixton and Clapham Camera Club will, on the 21st, be rewarded by a good attendance.

* * *

Messrs. A. B. Fleming & Co., of Caroline-park, Edinburgh, send us a copy of the picture, *Vanity Fair*, painted by S. Melton Fisher, and recently exhibited at the Royal Academy. For the benefit of those of our readers who do not know what phase of Vanity Fair the artist has chosen to treat, we may say that he has gone to a high-class drapery establishment, and caught a group of ladies in the act of selecting dress materials, &c. The opportunities such a subject affords for colour effects are obvious.

* * *

Of the reproduction to hand, Messrs. Fleming say that, with all its variety of colours, it was reproduced in three workings—yellow, red and blue—with inks of Messrs. Fleming's manufacture. The blocks were supplied by the Heliochrome Company, 122, Elgin-crescent, Notting Hill. It is a capital bit of work all through. Three-colour printing is gradually passing the obstacles that have so long barred its progress, and we may surely anticipate for it, in the near future, a very wide vogue.

* * *

A triumph of the art of reviewing appears in the *Daily Chronicle* of Friday last. Seventeen books on photography are "reviewed" in thirty-two lines. We give the "review" in full, because it may be instrumental in preventing some photographic publishers from again troubling the *Chronicle* to make its reviews of books on photography the opportunity for printing such confessions of photographic ignorance as the following:—

* * *

"This formidable array of books upon photography—nearly all of which are to be had at trifling cost—is but a portion of those which have been published during the last six months. Apparently, in photography, everything can be learnt from books, and therefore, if there is any photographic question which our readers desire to have solved, we recommend them to the appropriate volume in the above list. No doubt the books are most learned. For example, the first, on *Photogravure*, is, from the photographic standpoint, very well done indeed. The *Dictionary*, by Mr. Wall, is complete and up to date. We suppose there is text somewhere in Mr. Sturmey's *Annual*, there are hundreds of advertisements and a large number of illustrations. In fact many of these books, it seems to us, are published simply for the display of process blocks. Works like Captain Abney's *Platinotype* are scientific treatises, which probably only Captain Abney and one or two other men in the country are qualified to criticise and discuss. The entire collection is useful and valuable to photographers; but it is a collection of technical treatises by men who have made themselves specialists in photography—books to consult and books to study, books for the photographic workshop, but scarcely books to review in a newspaper, hardly books which may be described as literature."

* * *

We have received a letter from Mr. T. Gilbert Bowick, Chairman of the Executive Committee of the British Antarctic Expedition of 1896, appealing for funds to defray the cost of that expedition. Mr. Bowick's address is Royal London Yacht Club, 2, Saville-row, and he would, no doubt, be glad to give further particulars to those requiring them. The expedition is chiefly a scientific one, and, although we are not expressly told so, we assume that photography will play a large part in the observations that are to be taken.

THE INTENSIFICATION OF NEGATIVES AFTER DRYING.—I.

It not unfrequently happens that, after drying a negative and taking a print, it is found to be capable of improvement by means of judicious intensification, or the reverse—reduction; but many photographers are reluctant to meddle with matters as they stand, if a moderately satisfactory result is obtainable, in the belief that, after drying, the film is less amenable to successful treatment. To some slight extent this is actually the case, but, by suitable preparation, almost any film, after once drying, may be brought into a perfectly fit condition for the application of the usual methods of treatment. Naturally the means adopted will differ according to the character of the films, gelatine requiring totally different treatment from collodion, and a bath plate from one prepared from collodion emulsion.

We say that almost any film may be so treated, and practically it may be that all are susceptible of being brought into proper condition, though occasionally, under very abnormal circumstances, instances may be met with which refuse to give way to the ordinary processes. For instance, we have more than once met with gelatine negatives which, from some peculiarity in the character of the gelatine employed, coupled, no doubt, with the action thereon of the alum bath, have proved utterly beyond the reach of any form of intensifier or reducer, after they have been some time dried; and, in cases where chrome alum was used after development, we have known the films to refuse to fix, so thoroughly had the gelatine been hardened. Again, many years ago, when on a holiday tour, with collodion dry plates, in order to save trouble while away from home, the negatives developed were simply washed and dried without fixing, that operation being left until our return; but, after drying, it was found that the collodion was of so "horny" a character that it had become quite impervious, not only to aqueous solutions, but also resisted the penetrating action of alcohol, and in this case also the films refused to fix, although those treated immediately after development gave no trouble whatever. These and similar abnormal cases may, however, be left out of consideration.

In a general way, with gelatine plates, no special treatment will be required beyond a thorough soaking in water, but, before any absolutely uniform and complete action can be expected, the entire thickness of the film must be permeated. It is not of the slightest use to just moisten the surface of the plate before applying the intensifying or reducing liquids, as

this is only tantamount to courting failure; the film must be submitted to the action of clean, *soft* water, until the latter has soaked completely through the whole thickness and brought it to an even degree of saturation. The length of soaking necessary to bring about this result will vary according to circumstances, the character of the gelatine, the development used, and whether or not alum has been used in the process. Some plates will, in fact, require ten times the amount of soaking to bring them into suitable condition that others do, and, without knowing the plates, it is difficult to judge at sight when the proper stage has been reached. Generally speaking, those which appear to repel the water and to become quickly surface-dry may be set down as requiring a lengthy soaking, and this will usually be found to be the condition of plates that have remained a long time in the dry state, especially if alum has been applied to them before drying. Those, on the other hand, that take the water readily, and after a minute or so allow it to flow smoothly over the surface, will be ready for treatment after a comparatively short soaking; but, as there is no satisfactory method by which the exact minimum time can be ascertained, it is as well to allow plenty in all cases.

If it should occur, in spite of very prolonged soaking, that irregularity of action follows, it is pretty sure evidence that alum has been largely employed, either in the processs of manufacture of the gelatine or the films or in development, and steps will have to be taken to counteract its hardening action and to restore the permeability of the film. For this purpose nothing surpasses a weak solution of acetic acid, one part of the acid to one hundred of water, in which the plate should be soaked instead of in plain water. After the use of this bath the film should be further soaked in plain water to remove the acid, more especially if the subsequent treatment is to consist of reduction by means of hypo and ferridcyanide of potassium. A weak solution of ammonia or other alkali is also found to exercise a softening action, but this has also a tendency to rot the gelatine, which the acetic acid does not. The alkali must be thoroughly removed before applying such solutions as mercuric chloride, and in fact, wherever it is possible to dispense with either acid or alkali, it is preferable.

Salaries.—A lawsuit was reported in our last which was, no doubt, read with interest by many operators. It will be remembered that reference has been made in these columns several times during the last few months to the salaries offered by some photographers for skilled operators; also that there was considerable correspondence with regard to an advertisement for a skilled operator or retoucher. The salary offered in that case was twelve shillings a week, with board and lodging, for seven days' work, and it was alleged that there were several applicants for the berth. In another instance twenty-one shillings a week was offered for an "operator and all-round hand." However, the case reported last week shows that good houses still pay good salaries for competent operators. The plaintiff's engagement was for a term, and the salary the first year was five guineas, for the second five and a half, and for the third and following ones six guineas. This is quite refreshing reading after so much has been said about starvation wages of late.

Grinding the Edges of Glass.—In connexion with the method (see next page) of cleaning off old negatives, it occurs to us to remark that those who have worked with plates, with ground or smooth edges, will never regret the small amount of trouble involved in securing that comfort. All that is necessary is, when cleaning the plates, to have at hand a piece of ordinary flag stone, or one of the square-shaped scythe stones. Or, better than either, if one of the old-fashioned stone kitchen sinks be available, the process of cleaning may be carried out with the greatest comfort, and the sink itself will serve the purpose of grindstone. Take each plate singly, as cleaned, and pass each of the eight edges firmly, but lightly, once or twice across the grindstone. If lightly done, the sharp edge of the glass will be removed without causing any roughness; but, if any great force be applied, splinters and chips will be taken out, and a most unsightly edge formed. The time occupied (a few seconds), for each plate, is more than compensated for by the subsequent comfort in working.

Ladies' Nights at Societies.—The Bradford Photographic Society is to be congratulated on the success of its recent innovation—a Ladies' and Children's Night—which will now, doubtless, be repeated annually. In every society where these gatherings have been introduced they have proved the most popular nights of the year, even in societies and clubs where ladies are not eligible for membership. The old South London Society was the first, we think, to inaugurate these annual gatherings with lantern and music. For many years the Photographic Club has made a feature of its Ladies' Nights, and for a few years past it has had an extra night specially for children, when suitable amusements, sweets, &c., were provided for the youngsters. The London and Provincial have also had their Ladies' Nights. Other societies have them too, and in all they prove the most enjoyable nights of the year. Those societies that have not yet instituted an annual Ladies' Night on the lines of those referred to will do well to consider the matter before the lantern season is over; they will find that such entertainments will materially add to their popularity.

Photographs of Dark Flashes of Lightning.—This phenomenon, described by more than one experimenter, has always been looked upon with a questioning spirit; but of the reality of the appearance, whatever its cause, there can be no doubt. At a recent meeting of the Berlin Meteorological Society, Mr. Archenhold exhibited a negative showing this effect, the view having been taken last August. There was visible in the plate one narrow black flash on the dark field of the heavens above the brightly illuminated tree tops, and a second, much broader, bright flash, which was brighter than the tree tops. The opinion was expressed that probably the great intensity of the multiple flash may have led to the solarisation of its own image. It appears to us that a not unlikely explanation of the phenomenon would be that the intensely luminous image of the true flash would appear as a dark flash through reversal of the image, and that the actual image as thrown on the film may have been reflected from the back of the glass upon an adjacent part of the film, and become so reduced in luminosity as to give a developable image.

Abnormal Height of the Barometer.—The high readings of the barometer, during the greater part of last week, were very exceptional throughout England. On Thursday the highest reading reported to the Meteorological Office was at Ardossan, 31·09, which is an inch and quarter above the normal. It is said to be about the highest reading ever recorded in the British Isles. In London, on Friday, the mercury reached 30·92 inches, and it is stated that there have been only three occasions within the last hundred and twenty years, when the reading has exceeded 30·9 inches in the metropolis. The Meteorological Office have just made some modifications in the mean values published with the daily weather reports. The monthly means of the barometer and temperature are now given for the last twenty-five years. The new values show that in January the highest average of the barometer is at Jersey, where the mean is 30·01 inches, and the lowest in the north of Scotland, Sumburgh Head, 29·68 inches. What will perhaps interest photographers just now is the average of sunshine. It appears that the maximum is in Jersey, where, in January, it is seventy-one hours, and the minimum in London, where it is but twenty-six hours.

Photography and Chronographic Measurements.—A note on this subject, from a lecture by Mr. Frederick J. Smith, appears in a recent number of *Nature*. In order to avoid the error of "time-lag," introduced by the use of magnetic and solenoidal arrangements, he has devised a method based entirely on the use of light. Two sources of light at a suitable distance apart throw two beams of light on to a sensitive plate, carried in the carriage of a tram chronograph. By means of lenses the beams of light are caused to form two sharp images on the plate in a vertical line, one above the other, a tuning fork trace is also made on the plate; if the plate traverses when the beams of light are not interrupted, on development two black parallel lines appear on the plate; but, if during the passage of the plate the beams of light are cut by any solid object which shuts off the light, then, on development, two gaps are seen to exist. The distance between these markings, when interpreted in terms of the fork trace, gives the velocity of the object which cuts through the beam of light. In another method, the projectile cut during its flight through two thin screens, placed in the paths of the beams, and so opened a passage for the light. Two parallel lines are then formed on the plate, one longer than the other; the difference in their lengths duly interpreted gives the velocity of the projectile. This new mode of registering velocities would seem to be very valuable, as the most exact determination of the rapidity of the flight of projectiles at various stages is of great importance in artillery investigations.

The Solar Eclipse.—The eclipse of the sun which takes place in August next is already receiving attention at the hands of the joint Royal and Astronomical Societies' Permanent Committee. One of the tracks of the shadow, which is given as good for observations, is across Norway, Sweden, and Lapland, &c., a good station being at Vadso; it is where the English observers will be located. Photography, as a matter of course, will be an important feature of the expedition, and some new apparatus has been specially designed for the work. It is stated that Dr. Common will accompany the expedition, and will take photographs of certain parts of the corona, with a specially long-focus lens or mirror, with a view to settling some disputed points in connexion with it.

The coming eclipse has great attractions for the general public, inasmuch as the Vadso Station, where the English observers will be located, is easily comeatable, and the scenery on the way is very beautiful. We understand that Messrs. Gaze & Son have chartered a steamer of over 3000 tons, fitted with saloon and passenger berths, for a special cruise in connexion with the event. The vessel is timed to reach its destination some days before the eclipse occurs. The intervening time will be easily filled up by geologists, botanists, photographers, and excursionists generally in various ways. Conveniences for photographers on board the *Norse King* will not be overlooked, and some of the most picturesque places in Scandinavia will be visited during the cruise. This excursion will, doubtless, be duly appreciated by those photographers who desire an enjoyable trip to those northern lands, and can avail themselves of the opportunity.

The Great Photographic Discovery.—The extraordinary proportions given to the new discovery, as alluded to in our last, have now dwindled down to such an extent that we are able to give the subject close inspection. There is great probability that a discovery of importance has been made, to the effect that the radiations from a Crookes tube are not arrested by ordinary light-obstructors, but are capable of passing through so-called opaque objects, and exercising photographic action after their passage. If this simple effect prove to be obtainable, there are undoubtedly large possibilities in the future in connexion with such action. It will be remembered that the first announcement suggested the possibility of taking a photograph of the skeleton of a body clothed with its own integuments and surrounded by a textile fabric. Later accounts state, with regard to this idea, that "it is perhaps not strictly a photograph in the ordinary sense, because no lenses are used; it is not a negative, but a positive plate that is obtained." Except as showing that there's no photographic image, this sentence is devoid of meaning.

Professor Klupathy, of the Physical Institute of the University of Pesth, has repeated, "with very satisfactory results," Professor Röntgen's experiments. "The experiments in Vienna" (we quote from the *Standard*, which contained the first announcement of the discovery) "have not been successful up to the present," but Professor Röntgen has "sent rays of the new chemical light through aluminium plates of one and a half centimetre in thickness, and they went as clean through as if the substance had been wood," we learn; but it must be pointed out that camera-makers are inclined to look upon a much smaller thickness than that as being completely resistant to the entry of any hitherto-tried radiations.

A letter over the signature of A. A. C. Swinton, in that paper, states that, in conjunction with Mr. J. C. M. Stanton, the writer has been making experiments in the new direction, and further, that "in confirmation of Professor Röntgen's discovery, we have obtained distinct proof that the radiations in question do pass easily through various substances that are quite opaque to ordinary light, and do produce strong impressions upon ordinary photographic plates entirely encased in light-proof material. Indeed, all substances that we have so far experimented on in this laboratory appear to be transparent to their radiations, even sheets of ebonite, carbon, vulcanised fibre, copper aluminium, and iron." These excerpts would appear to be quite sufficient to show that we have a real discovery, the actual magnitude of which cannot at present be gauged.

Utilising Old Negatives.—There are many purposes to which old negative glass can be applied both by profeasionals and amateurs, but the trouble presents itself of getting it clean when wanted; consequently, old negatives, as a rule, are a "drug in the market." Yet, the process of cleaning, if undertaken systematically, is simple and easy in the extreme, and a few hours at this season of the year, when no other work presents itself, will provide a supply of clean glass for transparencies, for squeegeeing prints or for general purposes that will last until winter comes round again. If the negatives have been in use for printing purposes, their backs will be already clean, and the other surface, when stripped of its film of gelatine in the manner to be described, will scarcely require any further treatment, beyond rinsing in clean water to render it fit for recoating. The trouble is, in fact, less than with new glass.

Commence by marking, with a writing diamond or sharp file, one corner of the back or reverse side of each plate, so that, after stripping, the better surface may be recognisable, for, in addition to its being cleaner, the coated side will be freer from scratches than the other. Have the plates to be cleaned in a pile, and provide a dish capable of holding three or four at once, and also a bowl of clean cold water. Pour into the dish a sufficient quantity of saturated solution of alum, to each half-pint of which two ounces of ordinary hydrochloric acid, or spirits of salts, have been added. Immerse the plates one by one in the acid solution, and in about a minute's time the film will be loosened; take it out of the acid, rinse it lightly in clean water to avoid the action of the acid on the fingers as far as possible, and then, commencing at one corner, detach the film with a rubbing, rolling motion of the finger, and the whole will come away in a few seconds, leaving the surface of the glass perfectly clean. The acid alone will detach the film, but, at the same time, make it so rotten that it will break, and cause much trouble in removal, especially if the immersion in the acid is too long. The alum, by hardening the gelatine, prevents this, and the plates may be left to soak, two or three at a time, while another is being stripped. When stripped, transfer to a bowl or vessel of clean water, and leave to soak until a number are ready for drying; then dip singly into hot water, and dry with a soft cloth.

Perhaps preferably to drying the plates right off—at least when they are required for recoating, either with collodion or gelatine, a substratum may be applied to the glass after draining, and thus the trouble and time occupied in drying saved. If intended for use with collodion, no better substratum can be used than dilute albumen, made in the following manner:—Take the white of one egg and separate it from the yoke, add to it two or three ounces of water, and *stir, not beat*, vigorously but slowly, until the albumen is thoroughly mixed with the water; to that add, little by little, more water, thoroughly mixing it as added, until the quantity measures from thirty to forty ounces—the exact strength is immaterial between those limits—and a few drops of pure carbolic acid solution. Finally filter, and the substratum is ready for use, and can be flowed over the glass, wet or dry, nearly as easily as collodion. The only trouble will be to avoid bubbles, for which reason it will be well to pour from one vessel, and back into the filter. The substratum for plates to be coated with gelatine emulsion consists of a weak solution of gelatine and chrome alum; or, for that purpose, the glass may be dried without substratum.

JOTTINGS.

NATURALLY, my first act in commencing these "Jottings" for the year, is to tender my congratulations to the new Editor of the JOURNAL. I refrain, however, from saying anything of a commendatory or complimentary nature, for the simple reason that his reputation as a remorseless wielder of the blue pencil is such that it is extremely improbable he would "pass" my remarks. Hence, having humbly made my addition to the congratulatory chorus, I proceed to express the hope that I shall get on as well with the new Chief as I did with his predecessor, that the JOURNAL under his sway will advance and flourish, and that he himself will, to quote the remark of the funny uncle at the dinner party, "be a credit to his bringings-up and an ornament to his fire stove!"

The year that has just opened has witnessed the reshuffling of the cards of the game of life as played by millions in Europe, Africa, Asia, and America—in nearly the whole of the habitable globe, in fact, and the spirit of change and revolution that is abroad in the larger world has also projected its influence into our own small domain of photography. The photographic press and its *personnel* have been subjected to alterations and possibly improvement; gelatine is surely and certainly displacing wet collodion for process negatives; anastigmatic flat-fielded lenses are coming into general use so rapidly that the time cannot be far distant when they will be almost exclusively listed in opticians' catalogues; three-colour work seems commercially practicable; half-tone is sweeping all before it in illustration processes: rumours of the supersession of typography by photography are in the air; and the young bloods of the Royal Photographic Society have risen in revolt against the benevolent but elderly members of its Council, who have so long and creditably assisted in the management of the Society. Is it not all—particularly the last-named anarchical outbreak—enough to take one's breath away?

As regards the immediate future of the Royal Photographic Society, Captain Abney will, doubtless, be re-elected President, and, under all the circumstances of the case, the members could not make a better choice. It will not, I hope, have been forgotten that three years ago, after twelve months' office, he was personally desirous of not continuing as President; but the old ship had not got out of the shallows into which it had drifted a year before, and he therefore stuck to it for another term. If all I hear be true, the re-election of Captain Abney as President on the 11th of next month is the one thing that will prevent a very unpleasant split from occurring in the ranks of the Society.

The removal, temporarily or for good, of some half-dozen old members of Council must necessarily let in a corresponding number of more or less new and untried men, who, it is to be hoped, will form efficient substitutes for the men they displace. But, besides seeming to me callous and ungrateful to throw over an old servant mainly because he *is* old, and *has* served his constituents so well that they have been content to re-elect him year after year, the proceeding is possibly not unattended by grave risks. New blood, or too much of it, is apt to be impetuous and headstrong, and to lightheartedly engage in undertakings which men of mature years and judgment would not. The presence of age and experience on a deliberative or administrative Committee is not to be derided. Without some such steadying agency, the new Council of the Royal may get up to all sorts of tricks, such as the conferment of the Honorary Fellowship on Mr. H. P. Robinson, Mr. A. Maskell, or Mr. G. Davison; the admission of the Linked Ring to Affiliation; the bestowal of the Progress Medal on Dr. Burton Coxe; the increase of the Assistant Secretary's salary to 1000*l.* a year; and so on.

"Stranded," on page 15, asks a question that nobody has troubled to answer. He wants to know when a man is too old to be a photographer. Of course there is no hard-and-fast line to be drawn. "Stranded," however, appears to be considered too old at forty-six. Why, at forty-six a man is usually said to be in the prime of his life and powers. It is a hard lot. I should have been inclined to regard "Stranded's" experience as very exceptional but that so many bitter cases in which the question of age has been of paramount importance have lately come under my notice. Does professional photography, then, rank with drapers' shops, counting-houses, and similar walks of life, that desiderate what is called a good appearance, which means comparative youth, good clothes, and an Adonis-like bearing? Is a painter, a journalist, an author, a politician, a clergyman, a lawyer, an engineer, "too old" at forty-six?

A writer in a monthly contemporary, who signs "Major Kone," commits himself to several statements with regard to this JOURNAL, and those connected with it, which are neither in good taste nor accurate. He says he has been a reader of the JOURNAL ever since it started, that is, over forty years ago, and this should, although it does not, prove "Major Kone" to be old enough to know better than to occupy his time in disseminating fantastic and impertinent tittle-tattle about things of which he obviously possesses such knowledge as could only have been derived from the exercise of a disordered imagination on the groundwork of a dull and exiguous comprehension. But the writer is obviously not so "old" as he tries to make himself out to be. He says he buys his JOURNAL at the bookstall every Thursday morning. It is not seen on bookstalls on Thursday mornings—a fact which, of course, is immaterial to "Major Kone," whose other efforts to disguise his identity are not less clumsy and unsuccessful.

COSMOS.

CATHODIC PHOTOGRAPHY.

THE report, to which reference was made on page 26 of the last issue, and which originated in Vienna, is of such a nature as to astonish even old hands at photography; but, on careful examination, it will be seen that there is rather more in it than meets the eye at first sight.

It is, of course, well known that the haloid salts of silver are not only sensitive to light, but that invisible images capable of being developed are produced by pressure, by electricity, and by various chemicals, such, for instance, as the hypophosphites.

The following extract from Guillemin's *Electricity and Magnetism* page 371, edited by Professor Sylvanus Thompson, is not without interest or bearing upon this subject, as, at least, leading to considerable speculation as to whether these last experiments of Professor Röntgen do not support the theory that the action of light on the silver haloid is not rather photo-electrical than photo-chemical. In speaking of Faraday's discovery of the magnetic power of magnets on light, it is stated that Clerk Maxwell deduced the theory "that light itself is simply an electro-magnetic phenomenon; that which we call waves of light are not mechanical waves at all, but are immensely rapid electric displacements taking place in the all-per-

vading ether of space. . . . . It is believed by the editor of this work that this theory, which is now in the main accepted by all the younger generation of physicists, will be able, with proper modification and development, to explain the curious relation existing between electricity and the phosphorescent, fluorescent, and chemical properties of light."

Crookes, in his presidential address to the British Association in 1886, drew attention to an extremely graphic illustration of the grouping of the elements according to the periodic law, and, roughly speaking, this might be likened to a pendulum with ever-decreasing amplitude, and at various points the elements fall into line, being respectively electro-negative and electro-positive. Thus the four haloids, chlorine, bromine, iodine, and fluorine, are electro-negative, whilst silver is electro-positive. This being the case, then, might it not happen that, accepting the electro-magnetic theory of light as enunciated above, a film of silver haloid may be so affected by the electric displacement called light as to be disassociated? Minchin and Waterhouse have proved the passages of a current of electricity when light falls on a film of silver salts, and Mr. Bolas, in his affiliation lecture, suggested that the developer might merely close an electric circuit.

It is unnecessary to explain what is meant hy "cathodic," as most photographers will be aware of the so-called Crookes' radiant matter in vacuum or quasi-vacuum tubes. That the rays thus proceeding from the cathode are capable of exciting phosphorescence is proved by a paper upon this subject, which will be found in Eder's *Jahrbuch*, 1894, p. 204, by Ebert and Wiedemann. In the volume for 1895, p. 47, Ebert describes the most economical light, which consists of a compressed pellet of phosphorescent material enclosed in a glass tube, on the outside of which two tinfoil rings are cemented, and to which are connected the wires from the electrical machine; the cathodic rays cause the phosphorescent substance to shine with a total consumption of work or energy about two thousand times less than that required to maintain the normal amyl-acetate lamp. It will be remembered that, in the lectures delivered by Mr. Bolas in connexion with the affiliated societies, he sketched some such light as this as the light of the future.

These cathodic rays were first of all studied, so far as I can find, by Hittorf (*Wiedemann's Annalen*, xxxi.), but their action was studied photographically by M. Leuard, and a paper on the subject appeared in *La Nature*, July 28, 1894, p. 131. The method of obtaining them was to cement the cathode to one end of a tube of glass, the anode taking the form of a hollow brass cylinder applied to the sides, these being connected with an induction coil or Wimshurst machine. The rays are not directly visible, except in a vacuum or partial vacuum, and the absorbent power of gases for these rays increases with their density; they can also traverse thin sheets of metal and thick paper, wood, and many organic substances, but a sheet of quartz, ·5 mm. thick, immediately arrests them. In the article above cited are reproductions of photographs obtained by these rays, or possibly, what might be a better name for them, shadowgraphs, because it is obvious that, if metallic substances are opaque to these rays, whilst organic substances are transparent or permeable, the resulting photographs must be mere silhouette outlines, unless the rays form a penumbral shadow which might be reflected from the details of the surface of the metallic object. M. Leuard's experiments seem to prove that there are not perfect geometric shadows, but faint diffraction fringes, or penumbra.

There are many photographers, doubtless, who have access to instruments which will enable them to repeat Prof. Röntgen's experimcnts, and also many who are capable of explaining the phenomena, and whether they are directly or indirectly connected with the Hertzian waves. E. J. WALL.

PHOTOGRAPHIC WORKERS AT WORK.

I.—How Messrs. Newman & Guardia make a Hand Camera.

The letters "N. & G." on hand cameras and changing boxes are getting to be as well known amongst photographers as the figures "97," on an article not entirely unconnected with boots, are to the average domesticated specimen of the genus *homo*—and they convey to an outsider about as much meaning. To those interested in the subject, however, "N. & G." imply that the article upon which they are inscribed is as we need not tell our readers, the product of Messrs. Newman & Guardia; that it was made at their factory in the north of London, and reached the market through the establishment of the firm in Shaftesbury-avenue; and that, both as regards design and workmanship, it may be relied upon as being among the best.

It was with no small amount of interest, in seeing how the "N. & G." cameras came into existence, that we mounted to the top story of a large building in the neighbourhood of Kentish Town, noting on our way up that the firm had at least ample room for expansion downwards in the shape of two or three spacious and well-lit workshops. Arrived at the summit, we soon found ourselves in the glass-sided office from which Mr. Newman, the member of the firm who has charge of the works, is able to survey in the immediate foreground or in the far distance the whole of the factory.

Adjoining the office are the stores, in which are to be found not only the raw materials from which the cameras are made, but large numbers of the finished parts of all kinds ready to be made up into cameras and changing boxes as occasion demands. Here also is performed the little clerical work occasioned by the factory itself, the business transactions being carried on from the offices in Shaftesbury-avenue, under the superintendence of Mr. J. Guardia, the other half of the firm. Before leaving the office, to have the question at the head of this article answered in the most satisfactory way possible, Mr. Newman points out the collection of gauges and templates, without which such work as is carried on here would be impossible.

"If you get an order from abroad, say, for a changing box to fit one of your cameras, when it got out there and did not fit, you would hear of it?" we suggested.

"We should not hear of it." "It would fit," was the reply; "and this is how such a fit is secured. (Reaching down a substantial metal block and a hollow box of similar material.) Every changing box before it leaves the premises has to fit in that gauge" (pointing to the box), "and every camera has to be so made as to take this block," which we then noticed to be a dummy changing-box. "The two gauges are so adjusted as to ensure that, when this has been done, any changing box will fit any of our cameras made for that size of plate, so that such a *contretemps* is, as you see, absolutely prevented." In addition to these, there are hanging on the office walls, hundreds of templates, showing the exact sizes of the various parts to ensure proper fitting and accurate work.

"No piece work here," says Mr. Newman, "but we are able to see that we get our money's worth without it. Here! look at these parts;" and, so saying, he shows us a box of brass fittings (we were now in the stores), referring to a ticket, "they cost eightpence-halfpenny each the last time they were made, and, if the next man to do any runs the cost up, we shall soon guess that something is wrong, and he will hear of it."

The woodworking department was that part of the factory which first demanded attention. Here were to be seen camera cases and changing boxes in various stages of completion, from the mahogany, ebony, and pear-tree wood in the rough—these are the only woods employed in their products by Messrs. Newman & Guardia—to the finished article. It was here that we learned that the box portions of the changing boxes, like the Siamese twins, passed the earlier stages of their existence in pairs linked closely together, a surgical operation being required subsequently to separate each into two distinct boxes. Here also we learnt that, in addition to being carefully fitted together and glued, every camera case contains over a gross of screws. "It must add something to the weight," admits Mr. Newman; "but they are all the stronger for it."

Passing by the gas engine which provides, in an unobtrusive manner, the motive power for the machinery, we notice up near the roof an hexagonal box revolving by means of a band, and apparently unconnected with any of the many tools near it. On inquiry we learn that it is a "rumble," though that does not enlighten us much, until it is explained that little German silver or brass fittings after they leave the machine are placed in this box along with some polishing material, and revolved quietly for a period which apparently might be anything from a week to three months. "It just takes the extreme sharpness off the edges and gives them that nice soft feel."

In the general shop are to be seen the various metal parts in course of production, cameras being put together, shutters made, and the other incidental work of manufacture carried on. That this last item is not an altogether unimportant one is shown by the large quantity of special tools for making the various fittings, tools in a large measure designed and made on the premises. Under this head would be included dies for stamping sheet metal, tools for cutting toothed wheels, for bending and shaping plate sheaths, and so on—too numerous to mention, and occupying a considerable space both on the shop floor and, the smaller

articles these, in cupboards. The fact that the hands were employed on work where quality and not quantity was the motto was here very conspicuous. Every one seemed busy, and yet not too busy to be working *well*. Shutters, of course, occupied a consider share of attention, since these, especially of very high speed and those involving pneumatic regulation, are among the firm's specialities.

The exhibition of a shutter working in the five-hundredth part of a second starts Mr. Newman off on a dissertation on high speeds and how to obtain them, which, in our anxiety for good "copy," we are careful not to interrupt.

"If space," he says "is not a consideration and the shutter can be as large as you like, high speeds can easily be obtained. It is when the entire shutter has to be small enough to go in an ordinary size of hand camera that any difficulty arises. Then, it is not so difficult when the aperture of the lens is not a very large one. But, when the opening has to be, say, an inch and a half or more in diameter, becomes hard, since the two features to strive for, if very high speeds are required, are extreme lightness for the moving part, and the opportunity of letting it get well started before it actually uncovers the lens. You see at once that, the bigger the opening, the harder the fulfilment of these conditions becomes, bearing in mind, at the same time, the efficiency of the shutter. In this (a Celeritas shutter made to give exposures up to the one-five-hundredth part of a second) the speed is got by keeping the rotating disc as light as ever we can, by employing a strong steel spring as the driving power, and by allowing the disc to make one-third of an entire revolution before the actual exposure is given." That the speed of the shutter was actually as high as that given above, we subsequently had an opportunity of ascertaining for ourselves in the shutter-testing apparatus, which is made use of in every case before a shutter leaves the works.

It was in this part of the factory that we realised the difficulties thrown in the way of hand-camera makers by the new types of lens, which, however satisfactory from the user's point of view, have necessitated the expenditure of a large amount of ingenuity by those who aim at making a shutter to work between their lenses. The inner surfaces of the front and back combinations are so near one another, that it is astonishing to the non-mechanical mind that not only an iris diaphragm, but an instantaneous shutter, can be constructed to work between them.

Here, too, we were shown hand cameras to take the new Satz anastigmats, each of which means practically three distinct lenses of different foci; and, when we say that the longest of the three is, for a quarter-plate size, a shade over eleven inches, it will be seen that the camera is required to rack out to a considerable length. Still a design has been brought out which accomplishes this without any undue increase in bulk or weight, and the remarkable capabilities of the lens are so placed at the disposal of the hand-camera worker.

A reference to the clock informs us that we have already trespassed on Mr. Newman's valuable time, for a period which, were we ourselves the sufferers, we should, probably, bitterly resent, but a movement of departure brings forth the remark that "there is one point in all our designs I have not referred to. You will notice here, and here, and here" (suiting the action to the word and pointing out his meaning on a hand camera lying near), "we always endeavour to arrange things so that every working part can, if necessary, be readily got at from the outside, without pulling the camera to pieces." Seeing that we cast envious glances at the instrument in his hands, he incidentally remarks that its price is about eighteen pounds.

"An N. & G. camera is a luxury indeed," say we.

"We hold that for the best possible work it is a necessity," replies Mr. Newman. "That" (pointing to an oubliette-like gap by the side of the staircase, intended one day to accommodate a lift), "that is the shortest way down. Good-bye."

We preferred the longer route by the stairs.

THE PERFECTED PHOTO-CHROMOSCOPE.

At the Camera Club, on Thursday evening last week, Mr. Frederick E. Ives read a paper on the above instrument, upon which he has been working for the last two years. He met with a most hearty welcome from the members, who mustered in such numbers that the large room at the Club was crammed to suffocation, so much so that the electric fan had to be kept at work almost constantly to clear the air. Mr. Ives illustrated his paper with lantern slides, and he also called in to his aid the spectroscope, and the polariscope. And here let it be noted that his experiments were carried out with a neatness and entire absence of mishap, which is far from common even when an expert lecturer is addressing an audience. This perfection of results was, in great measure, due to the form of lantern adopted by Mr. Ives. It is not patented, and the lecturer expressly mentioned this circumstance, telling his audience that any one was at liberty to copy its design. It is a small lantern, employing the electric arc light, with a sliding front, so that the ordinary lantern nozzle, the polariscope, and, say, a projection microscope, can at will, and with only a second's pause, be brought in front of the light. As an example of what can be done by the instrument, we may mention that he showed the spectrum, and at the same time exhibited a piece of coloured glass, in order to illustrate what particular parts of the band of colour were absorbed by the medium. Captain Abney, who occupied the chair, made some exceedingly complimentary remarks concerning this lantern, and indicated that it was the best apparatus of the kind which had yet come under his notice. We will now give a *resumé* of Mr. Ives's paper.

He first of all alluded to a paper which, in 1893, he had read before the Camera Club, in which he described his original photo-chromoscope, an instrument which, while giving fine results, had complications of construction which seriously interfered with its practical use, the necessary cleansing of the mirrors and lenses causing fresh adjustments which could not readily be performed by an unskilled hand. The old instrument, at the same time, compared unfavourably with the one which he had now perfected, for it was monocular, the new one showing a stereoscopic image. The old instrument, he admitted, presented an advance upon previous efforts in the same direction; but the defects to which he had alluded had to be overcome, and the result of his labours was the perfected photo-chromoscope, which would presently be submitted to consideration. The new instrument, he might mention, was so simple that a child could adjust it. The image was viewed by both eyes,

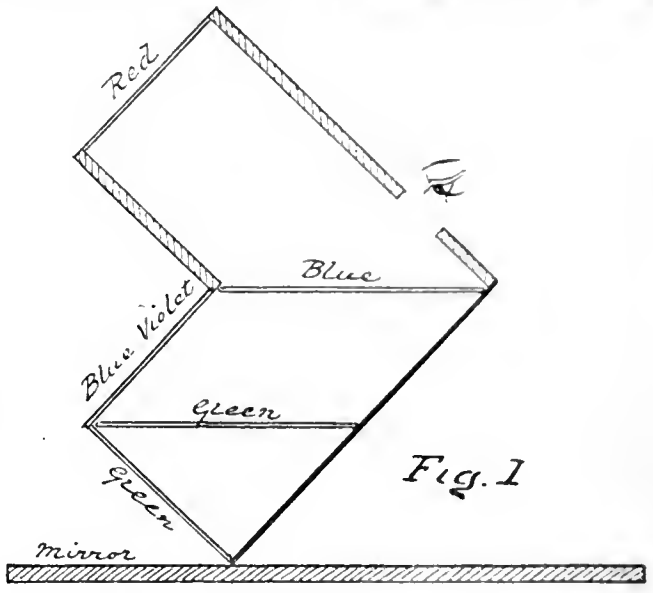

Fig. 1

and it compared very favourably with its prototype, both in simplicity and also in price. It might be described as a box furnished with five pieces of coloured glass, a reflecting mirror, and a pair of lenses (see fig 1)

In his former paper he had described to the Camera Club the principles upon which the instrument was constructed, and it would be futile before such an audience to talk generally upon the phenomena of light; but, in case there should be present any who were absent on the occasion of his last lecture, he would enter into a few details, and would illustrate his remarks, as far as possible, by lantern slides. Another object which he had in view was to show them some new apparatus which he had devised to illustrate the science of colour, and he thought that this apparatus would be a subject of interest to his auditors.

After alluding to the importance of light as a form of energy upon which all life is dependent, and to the wave motion which is characteristic of it, he showed how white light could be split up into its constituent coloured rays by means of a grating, or by a prism. It was only by experimenting with the spectrum, and by submitting a sensitive plate to the influence of different parts of that spectrum, that we can arrive at the solution of many photographic problems.

After throwing an image of the spectrum upon the lantern screen, the lecturer showed why, in white light, most objects exhibit colour. a red glass showing red because it absorbed, or stopped, nearly all the rays except the red, the same result for green or any other colour being brought about by using glasses of each specific tint. But most of the colours of nature are not so simple as these, pink, for instance, as he would demonstrate, being a mixture of all the colours of the spectrum except the yellow-green. Yellow is another colour which is usually very impure, and, although it was at one time regarded as a primary, the simple experiment he now showed would prove that it is made up of green, orange, yellow, and red. A combination of didymium glass and aniline yellow, which he now placed in the lantern, would prove that it was not

even necessary to have any spectrum yellow present for this particular combination, which was brilliant enough to the eye when analysed by the spectrum, is seen to be made up of red, orange, and green.

Although the colours of nature are due to the specific absorption of part of the spectrum tints, many objects, which, like window glass, will transmit all the spectrum rays, will give exquisite colours when exhibited in thin films, or by means of the polariscope. A ray of light passing through a crystal of Iceland spar becomes divided into two rays, a fact which Mr. Ives illustrated in a beautiful and novel manner by holding such a crystal in front of a lantern slide of a statue, the image on the screen being immediately doubled. He then showed how, by cutting the spar and cementing it together in a particular way, it became a polarising prism, passing only one of the polarised rays. Here, again, came another very neat illustration, a verbal one only, it is true, but so ingenious as to call forth a little murmur of approval. Mr. Ives said that the relation which a ray coming through a polarising prism bears to another polarising prism is like that which exists between a paling and a flat board; turned on edge, the board will pass through easily, but, turn it half way round, and it will be refused admission. By means of two prisms, the passage and stoppage of the light was shown on the screen, and it was also shown that, when some other double refracting substance was introduced between the prisms, the ray is broken up and twisted, so that it will once more find passage.

The light ray having been analysed, the next thing to consider is its photographic action. The older theory was to split up the spectrum into three divisions—heat, light, and actinism—the heat rays mingling with the light rays at the red end, and the actinic rays overlapping the blue and violet at the other end. A great improvement in photography was indicated by the introduction of isochromatic plates, by which the reproach of dark colours being rendered light, and *vice versâ*, which had always attached to photographic pictures, had at last been removed. He now showed a series of pictures which exhibited the colour-sensitising action of certain dyes, the plates having been made some time ago with collodio-bromide emulsion, and he would in each case compare a picture on the dyed plate with one taken on the same description of plate undyed. We thus learn that all the light rays, notwithstanding their colour, possess the property of actinism, and we also see how we can, by the use of specific dyes, suppress the action of any ray not wanted by the interposition of a colour filter. When one has mastered the subject, it becomes a comparatively easy matter to translate all colours into substantially correct monochrome.

It must be remembered, as a most important point, that colour does not depend upon wave-length only, and, although the hues of different parts of the spectrum have their fixed wave-lengths, some of the brightest can be reproduced to the eye by the mixture of other spectrum colours, as already shown in the case of the didydium glass. Indeed, experiment shows that all the colours of the spectrum can be reproduced, as well as white light, by definite mixtures of deep red, green, and blue-violet. The Young-Helmholtz theory assumes that there are three colour sensations in the brain, each being associated with one of these colours, all other colours being the result of compound sensations. Clerk Maxwell made measurements and plotted curves to show in what proportions these fundamental colours were mixed to produce the other tints of the spectrum. Upon these observations and experiments is based the photo-chromoscope.

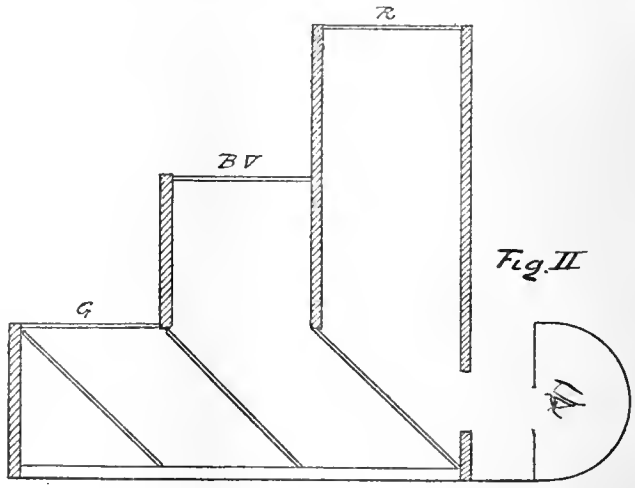
An object having been chosen for representation in the instrument, three photographs are made of it, each being produced by the joint action of the respective fundamental colour, in its due proportions, and all other hues into which it must enter in the reproduction. The resulting positive image must, however, be viewed by the light of the fundamental colour only. In other words the three necessary photographic negatives are made by mixtures of spectrum colours, but the positives taken from them are associated with approximately pure red, green, and blue-violet screens, and mingled into one image which is projected upon the retina. By this means a true colour record of any object can be obtained, and such records can, at will, be translated into colours in the photo-chromoscope or can be utilised for triple lantern projection.

Mr. Ives then pointed out that for his purpose Maxwell's colour curves required certain modifications, a matter to which he had referred in detail in an article published in the *Photographic Times Annual* for 1885. He had therefore, and at Captain Abney's suggestion, he might say, slightly modified Maxwell's curves for his own use, and some pretty severe tests have shown these modifications to have been justified. To obtain absolute perfect results, from a theoretical point of view, four reproduction colours, violet, blue-green, green, and red are necessary, and when three colours only are used there must be a slight degradation, but he had succeeded in distributing this until it appeared only as a trace of atmosphere, a fault that in London at least could hardly be considered as unnatural.

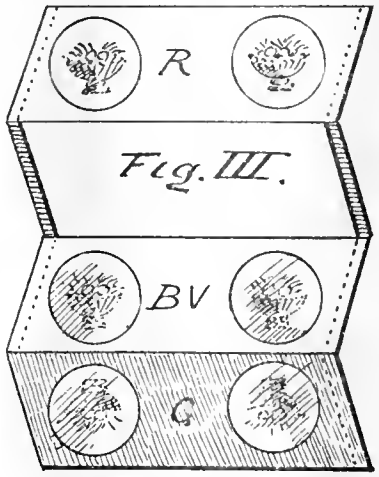
By lantern projection the results obtained are not so good as by his photo-chromoscope, but, as a means of demonstrating the principles upon which the instrument is based, it is valuable. (The lecturer here showed on the screen three separate chromograms, each covered with its suitable coloured glass. By rotating in turn the prism fixed in each of the three lenses which had now for the purpose been attached to the lantern front, the three images were superposed, with the result that the colours blended in the most beautiful and natural manner to form a perfect picture.) He explained that, in order to show such projections on a large scale, it would be necessary not only to employ three lantern objectives, but an arc light for each; and, that as this arrangement was almost prohibitive on account of its inconvenience and expense, he preferred to limit himself to lantern pictures produced in a way he had shown at the Camera Club two years ago. These were made by combining on one glass three films of different colours. Several of these pictures he now exhibited.

Composite colour photography could have very few practical applications so long as it was necessary to take separate negatives by separate exposures, and to project separate positives on a screen by means of a triple lantern. But he had now designed a camera which is as simple as a Kodak for taking the necessary negatives by one operation, and, when positives were made from such negatives and placed in the photo-chromoscope, the result was wholly satisfying to the eye. Moreover, the work will be well within the powers of the ordinary amateur photographer, and even those who do not care to meddle with camera or lens can have an instrument with chromograms supplied, which will be an endless source of delight to them. It is true that this process does not give a fixed coloured image, such as the world has been looking for so long, but he had indicated by his compound lantern slides how, at least, very satisfactory coloured images could be produced from the photo-chromoscope negatives. For his part, he considered that an image, showing colours and stereoscopic relief, was a far more satisfactory thing to achieve, although the obligation to view the picture in special apparatus might limit its applications.

The photo-chromoscope suggested in its form a flight of steps. In its



first model it had three steps as shown in fig. 2, and at the top of each step a chromogram (the three pictures being placed in a hinged frame, see fig. 3, so as to fold over) was placed in association with its proper colour screen. Now, the instrument is made as shown in fig. 1, having



only two steps, the lowermost image being viewed directly, not by reflection, as in the case of the other two images.

He must protest against the fact that the three-step arrangement has been credited by some of the journals to a German. But he could show that his drawing of this construction appeared as part of his complete patent specification, which he filed in the United States Patent Office,

several months before the German inventor made his claim. Claims have been made by others, but the instruments with which they are credited are incapable, either in fact or theory, of performing the functions of a true photo-chromoscope.

THE PHOTOGRAPHIC COPYRIGHT UNION.

"When last I wrote, congratulating the Photographic Copyright Union on the good work it had already accomplished," writes "An Unionist," in the *Photographer's Record*, "and on its sound and satisfactory position, I had no idea that in another short three months it would have made such rapid strides as it has done; for not only has it increased in popularity, in wealth, and in the number of its members, but it has evinced to the world a liberal and far-seeing policy.

"The Annual General Meeting, held at St. James's Hall on November 22, was well attended, and a great success. Several important modifications were made in the rules, to wit, (*a*) All photographers, whether professional or amateur, who would care to join, are invited to do so; (*b*) the annual subscription of 10s. 6*d.* is abolished, and membership now costs absolutely nothing.

"Through the instrumentality of the Union, kindred societies have been established in France and the United States, whilst another one is in course of formation in Germany, so that it may safely be predicted that the Photographic Copyright Union will be an international affair.

"With regard to the correspondence which appeared in the *Times* a few weeks ago, but one opinion can be formed. A certain section of the illustrated press showed its annoyance at having to pay a moderate fee for what, before the formation of the Union, it was in the habit of obtaining for nothing; and its intention was to endeavour to dissuade celebrities from giving free sittings, by which the photographer would be deprived of the copyright therein, and the journalist would accordingly have the benefit, free of cost, of the photographer's skill, labour, and outlay. The movement, however, has missed its purpose; for I am assured by several of the leading men in the photographic world that the intemperate correspondence referred to has not had the slightest influence upon their business. Nay, more, I have no hesitation in asserting that, had these letters had their desired effect, in six months' time not only their inspirers, but also the *respectable* portion of the illustrated press, would have nothing to fill the papers with. And why? Because not one celebrity in fifty would think of sitting for his photograph *unless asked!*

"The future policy of journalists and photographers is to work amicably together to their mutual advantage. Let the journalist submit with a good grace to the inevitable, and pay a small fee for the use of the photographer's productions, which are as much his legal property as anything else can be. But, at the same time, it is to be hoped that no photographer will charge a copyright fee for the use of a photograph which is *not* copyright.

"Before closing this short article, I should like to say a word or two with regard to registering copyright photographs. It has been suggested that I am altogether wrong in the assertions I made in my last article with regard to the existing law; but perhaps I did not explain myself with sufficient clearness. I again affirm that, if a photographer takes a photograph of any person on his own behalf, and without payment from the sitter, from the moment the negative is taken the copyright is the photographer's. Registration or non-registration does not affect the copyright in the least. The photographer may register whenever he pleases, though he cannot avail himself of any statutory remedies until it is registered; but, if a copyright picture is pirated *before* registration, he can subsequently register, when he is entitled to avail himself of all statutory remedies against the reproducer for all copies sold *after* registration.

"In conclusion, I would earnestly urge journalists and photographers to meet each other on honourable, straightforward, and business terms, when I feel sure that there will be an end to grumbling on either side."

THE TRAILL TAYLOR MEMORIAL.

The Executive Committee, appointed at the meeting held on December 20 last, met for the first time on Wednesday, January 8, at the rooms of the Royal Photographic Society. Their first act was to exercise the power given them of adding to their number by inviting Mr. R. Child Bayley to join in their deliberations. After long and careful consideration of the various suggestions that have been made with regard to the form the memorial should take, it was decided unanimously that it should take the form of a lectureship in connexion with photography, and that the lectures should be delivered in London, or in the provinces, according to circumstances, and as the controlling body for the time being might decide.

It was further resolved that the fund should be administered by a Committee to be elected triennially, and to consist of an equal number of London and of country members; the first Committee to be appointed by the General Committee of the fund.

The strongest desire was expressed by the Committee that it should be understood that it was their intention, as far as possible, to provide that the benefits of the fund should be made available for country photographers as well as London ones, and that country photographers should be fairly represented on the governing body.

Until some idea could be formed of the amount of money likely to be subscribed, it was, of course, impossible to discuss details of the application of the funds, but a hope and belief were expressed that the Committee would have a sum of not less than 500*l.* to deal with.

PROCESS ENGRAVING AND ITS REMUNERATION.

The Directors of the Electrotypers, Stereotypers, Process and General Engravers' Association, which is registered for the protection and advancement of the interests of the trades embodied in its title, have given much consideration to the serious question of the low prices now ruling for process engraving, both line and half-tone, and, being convinced that unless some united action be taken to check that depreciation the industry will be practically ruined by being rendered unremunerative, they convened a meeting of the trade representatives on Monday afternoon at Anderton's Hotel for the purpose of endeavouring to fix a standard rate, at least as regards minimum prices.

Mr. W. Boutall presided, and pointed out that the meeting had been convened for the purpose of considering any practical scheme for the improvement of the present condition of the process and engraving business, a trade, he observed, which had almost sprung up during the last quarter of a century, and had now assumed considerable magnitude, and had almost become one of the staple trades of the country. It was, however, only in the beginning of last year that they had obtained an organization. The present deplorable condition of the industry was mainly due to the fact that every man had been doing what seemed right in his own eyes, and paying little regard to the surrounding conditions of the industry taken as a whole. The matter of price, however, had been the result, to a large extent, of accidental circumstances, such as the cost of production, wages, materials, and the different charges which went to make up the aggregate of the cost of the work. Many other considerations were also involved which did not apply in the case of an ordinary manufacturing industry. Mr. Boutall pointed out that the process-engraving trade was rather of the nature of an artistic industry, and he considered artistic merit of itself ought to have a very considerable influence not merely upon the result which they produced, but upon the price obtained for it. The industry having advanced very considerably, it had been perfectly legitimate that a certain proportion of the benefit which arose from its importance should have been given to the customer; but it had been represented to them that a very much larger proportion of the benefit had been given to the customer than was ever called for by the circumstances of the case. The Directors, Mr. Boutall observed, had given very careful consideration to the question, and had resolved that the better course was to ask for an expression of outside opinions, so as to obtain some common basis which would afford ground for future operations, and hence the convening of that meeting, which he hoped would result in something practicable being resolved upon.

A spirited discussion then ensued, it being eventually resolved that a ballot should be taken to fix the net minimum prices which should

prevail in the trade as the current prices for line and half-tone proce engraving work, both as to the rate per square inch and also as to the minimum for single blocks. It was further resolved that the meeting should be adjourned, and that the result of the ballot should be made known by the Secretary, Mr. George Holloway, and that the opinions of absent representative firms should be obtained.

The Inquirer.

*** *In this column we shall, from time to time, print questions that may be addressed to individual contributors to our pages, or such as are sent to us with the view of eliciting information from a variety of sources. We invite the co-operation of our readers in rendering this feature of the* JOURNAL *useful and instructive.*

PYRO FORMULA (to Mr. E. Dunmore).—E. A. GOWARD says: "In the *Photographers' Companion*, on p. 126, under the heading of Formulæ, the following is given:—

Carbonate of Soda Developers.

A.—Pure carbonate of soda	6 ounces.
Water	80 „
B.—Pyrogallic acid	1 ounce.
Sulphite of soda	6 ounces.
Sulphuric acid	1 drachm.
Water	1 ounce.

For use, equal parts of each.

The bulk of water for the B solution seems entirely out of proportion to A, taking into consideration the fact that equal parts of A and B are to be used. Is there not an error somewhere?"—In reply: The quantity of water in B should, we believe, be 80 ounces.

DEVELOPER FOR MICROPHOTOGRAPHS.—PLATO says: "1. I have been reducing some quarter-plate portraits, and employ an inch power of my microscope, and have got on fairly well, but I find I want a particular developer for the purpose. The one I use is:—

Iron	1 drachm.
Acetic acid	2 drachms.
Spirit	2 „
Water	12 ounces.

When I put these under the microscope, some are very good and sharp, that is, if the developer is stopped at the right moment; if left on a little too long, it appears a little out of focus, but I find it is owing to a slight deposit that takes place, and show it very much with a higher power. Now, can any one tell me of a developer that will be an improvement? I may say that I have tried a pyro developer and find it the same. 2. Will some one please give the formulæ suited for the albumen plates prepared by Dr. Ryley, as mentioned in the ALMANAC? There is no formula for developing given."

ACETYLENE (to Mr. Edwin Banks).—W. THOMPSON writes: "I have for a long time used the Welsbach incandescent light for enlarging, and also two of them in a reducing camera. My gas supply has, however, totally failed me, and I am in a dilemma. Your article on acetylene, of January 3, has made me wonder whether I can instal this as a new source of light; but I would like a sketch of the generator and sizes given. Could you favour me with this or refer me to any source from which I could get it? I am afraid I cannot afford to buy any commercial plant, but am in a position to have anything made. I gather from your article that the light is safe, and the burner you recommend is suited to projection. I would esteem any information as to the form of generator as a very great favour, and it would be of great aid to me."

DYES FOR MORDANTS.—J. C. W. says: "In reference to the article (in December 27 number) on photographic mordants, I should be much obliged if you could give me, in your correspondence column, a few hints as to suitable dyes to use. I have tried some of Judson's dyes which are not supposed to dye cotton, and while some—as for example, the green—leave the cotton white, they do not dye the (chromic) mordant sufficiently, others stain both cotton and image. Either a list of a few dyes or a few general hints would be useful. I cannot find any particulars as to the properties of dyes and mordants in any of the books of reference on which I can lay hand."

News and Notes.

ROYAL PHOTOGRAPHIC SOCIETY.—Photo-mechanical Meeting, Tuesday, January 21, at eight p.m., at 12, Hanover-square, W. *On Irregular-grained Screens*, by Mr. E. Sanger Shepherd.

THE Borough Polytechnic Photographic Society, 103, Borough-road, of which Mr. Alfred Bedding is chairman, only started in November, and now numbers thirty members. An attractive programme for the session has been issued.

IN connexion with the Seventh Annual Eisteddfod, to be held at the Tolmer's Institute, Drummond-street, N.W., on Monday evening, February 3, there will be a photographic competition. Mr. H. Dixon has been chosen as Judge. The competition is open. Particulars may be obtained of Messrs. Gall & Swain, 171, Tufnell Park-road, N.W.

LEICESTER AND LEICESTERSHIRE PHOTOGRAPHIC SOCIETY.—The following officers for 1896 were elected at the Annual Meeting held January 9:—*President:* Mr. G. Bankart.—*Vice-President:* Mr. T. W. Gamble.—*Committee:* Messrs. W. J. Coates, W. Murray, J. Porritt, S. Squire.—*Treasurer:* Mr. J. Toone.—*Secretary:* Mr. T. Brown, 68, Church-gate.

GLASGOW "EVENING TIMES" CAMERA CLUB.—The winter Exhibition of this Club will be held in the rooms at 46, Gordon-street, Glasgow. The Exhibition will open on Monday, February 3, and remain open until Saturday, February 29, 1896. The Open Class is: H, Landscape, Seascape, Architecture, set of three, one silver and one bronze medal. In this class there will be an entry fee of 2*s.* 6*d.* for each set of three. Communications respecting the Exhibition should be addressed to the Secretary, Mr. H. C. Shelley, *Evening Times* Camera Club, 46, Gordon-street, Glasgow.

PHOTOGRAPHIC CLUB.—The next weekly meeting of the Club will be held in the Club-room at Anderton's Hotel, Fleet-street, E.C., at eight o'clock on Wednesday evening, January 22. The meeting will be devoted to *Further Tests with Limelight Jets*, under the direction of Messrs. C. E. Hearson and Andrew Pringle. All jets for trial must be delivered at the Club room by seven o'clock on the 22nd, and must be ticketed with exhibitor's *nom-de-plume* or number, A sealed envelope, containing the exhibitor's name, should accompany the jets. The name of the maker of the successful jet will not be published in the Club report.

WE are glad to hear that no further action has been taken in the matter of the alleged infringement of Dr. Albert's patent, to which we referred last month. The inference is either that the patent is hardly considered of sufficient validity, or the crossing of the lines in the alleged infringing prints was not at the angles claimed by the patent. This latter was the case, but the patent is so wide in claiming for crossings "about 60 or 30 degrees," that, if worth anything at all, it could surely have been made to cover the case in point. The more probable reason is that the plaintiffs in the action did not think it worth while risking a heavy lawsuit.—*Process Work.*

Patent News.

THE following applications for Patents were made between January 1 and 11, 1896:—

PLATE HOLDER.—No. 67. "An Improved Plate-holder or Carrier for Detective and other Photographic Cameras." R. KRÜGENER.

MOUNTING TRANSPARENCIES.—No. 93. "Method of Mounting and Storing Transparent Photographs." J. JOLY.

DEVELOPING BATH AND DIPPER.—No. 150. "An Improved Form of Bath and Dippers for Fixing Photographic Plates." W. TYLAR.

HAND CAMERA.—No. 231. "A Magazine Hand Camera." H. PRADEAU.

PRINTING.—No. 352. "An Improvement in Photographic Printing." E. D. PERCIVAL.

DEVELOPERS.—No. 371. "Improvements in Photographic Developers." Communicated by Lembach & Schleicher. A. M. CLARK.

IMPROVED "METHOD."—No. 450. "An Improved Method in Photography." G. J. BULL and B. F. C. COSTELLOE.

SCREENS.—No. 507. "Improved Screens for use in Photo-mechanical Process Work, and in the Three-colour Process of Photography." J. B. FINDLAY.

CHANGING BACK.—No. 681. "Improvements in Photographic Apparatus for Changing Sensitive Surfaces Arranged as a Pack." J. D. LYSAGHT.

PHOTOGRAPH STAND.—No. 688. "An Improved Stand or Rack for displaying Cards, Photographs, and other Articles." H. C. HALL.

STEREOSCOPES.—No. 700. "An Improvement in Stereoscopes." J. CARPENTER and L. GAUMONT.

CAMERAS.—No. 789. "Improvements in Photographic Cameras." L. HOLMES, L. E. HOLMES, and H. HOLMES.

THE ROYAL PHOTOGRAPHIC SOCIETY'S PROGRESS MEDAL.

We are informed that, at their last meeting, the Council of the Royal Photographic Society unanimously awarded Mr. Thomas R. Dallmeyer the progress medal of the Society in recognition of his work in connexion with the tele-photographic lens. We congratulate Mr. Dallmeyer on the distinction of which he has been made the recipient, and are sure it will be universally regarded as having been well deserved and well bestowed.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK

January.	Name of Society.	Subject
20	Camera Club	*Exposure and Development.* Captain W. de W. Abney, C.B., R.E.
20	Richmond	*Shutters.* C. W. Harris.
20	South London	Lantern Evening. Prize Slides.
20	Walthamstow	*Lantern Manipulation.* A. Rose.
21	Brixton and Clapham	*Printing Processes of To-day.*—IV. Photogravure. A. E. Smith.
21	Gospel Oak	*Lantern-slide Making.* C. Morris
21	Royal Photographic Society	*On Irregular-grained Screens.* E. Sanger Shepherd
22	Ashton-under-Lyne	Exhibition of Members' Lantern Slides from Views taken on Ramble to Shrewsbury. John Wilson, J.P.
22	Borough Polytechnic	Members' Open Night.
22	Camera Club	Demonstration of the Photo-Autocopyist by the Autocopyist Company.
22	Croydon Camera Club	Practice in Flashlight Work
22	Leytonstone	*My Favourite Developer, and How Used.* A. E. Bailey.
22	Photographic Club	Further Tests with Limelight Jets, under the direction of C. E. Hearson and Andrew Pringle, F.R.M.S.
22	Putney	*Perspective and Composition in Pictures —Photographic or otherwise.* W. R. Stretton.
22	Southport	Silver Printing.
23	Bradford	*The Utility of Photography.* Percy Lund.
23	Camera Club	Lantern Evening. Major Lysaght and Mr. Davis.
23	Ireland	*Convention of 1895.* Messrs. Ruthven and Werner.
23	Liverpool Amateur	Lantern in Use.
23	Oldham	*How to Make a Lantern Slide.* W. A. Nash.
23	Woolwich Photo. Society	*The Preparation of Gelatino-chloride and Plain Salted Papers.* G. H. Mess.
24	Birkenhead Photo. Asso.	*Photo-micrography.* The President.
24	Croydon Microscopical	Demonstration of Toning the Venus Printing-out Papers by Various Methods. C. H. Burnaby Sparrow.

ROYAL PHOTOGRAPHIC SOCIETY.

JANUARY 14,—Ordinary Meeting.—Mr. John Spiller, F.I.C., F.C.S., in the chair.

Six applications for membership were received, and thirteen new members were elected.

Mr. H. L. ALDIS, B.A. (Cantab.) read a paper entitled

ASTIGMATISM AND A NEW "STIGMATIC LENS."

The paper commenced with a sketch of the nature of pencils of light showing astigmatism and other aberrations, without special reference to any particular forms of optical systems, and proceeded to deal with the effect in a small incident pencil of the refractions it undergoes in passing through an optical system. Both the primary and secondary curvatures depend in general on the position of the stop, on the distance of the object from the lens, and on the nature of the optical system; but there was this relation between the primary and secondary curvatures of the image that, if from the curvature in the primary plane there were subtracted three times the curvature in the secondary plane, there would be obtained a quantity independent: (1) of the position of the stop; (2) of the distance of the object; and (3) of the thicknesses of the component lenses of the system and of their separations. Sir George Airy, the late Astronomer Royal, proved this result for an optical system, in which the component lenses were indefinitely thin, but apparently did not see that it applied to a system of thick lenses. In consequence of this law, the labour of the construction of lenses on a purely theoretical basis was much lightened, it being only necessary to consider the action of the optical system on the rays of pencils which lie in the primary plane; for instance, in constructing an optical system giving zero curvature in the primary plane, the curvature of the secondary plane could be deduced from the knowledge of the astigmatic constant of the system, and it was one condition of an optical system with a flat field free from astigmatism that the astigmatic constant must vanish. The simplest form of a stigmat lens consisted of a glass plate with parallel plane sides; but, as such a lens had an infinite focal length, it was necessary to modify it in such a way as to obtain a positive focus without altering the astigmatic constant, and the paper then dealt with some lenses exhibiting the principal methods by which the requisite correction was obtained. The question of spherical aberration was next dealt with, and Mr. Aldis concluded by showing a diagram of the first lens he had worked out, and which resembled in general form the type of portrait lens introduced by the late J. H. Dallmeyer in 1866, the chief points of difference being (1) that the back combination was a weak negative lens instead of a positive lens; (2) the refractive indices of the cemented lenses forming the front combination were all high and nearly equal; the back combination was formed of crown-shaped lenses of high refractive index and flint-shaped lenses of low refractive index; and (3) the front lens was an unusually deep meniscus. A diagram and description of the lens is given on page 807 of last year's volume of THE BRITISH JOURNAL OF PHOTOGRAPHY.

A short discussion followed, in which Mr. BECK and Mr. DALLMEYER took part.

Mr. BIRT ACRES then demonstrated an apparatus which he had invented, and to which he had given the name of

THE KINETIC LANTERN,

the object of which was to throw upon the screen a series of photographs in such rapid succession as to convey the idea of natural motion. The photographs shown were taken at the rate of about forty per second, and were projected at the rate of about fifteen per second, the result being similar to that of Edison's kinetoscope. The examples shown included boxers, a review at Kiel by the German Emperor, Epsom Downs and the Derby, serpentine dancing, and breaking waves, and the opinion of the meeting was unmistakably evidenced by the loud applause which greeted the various effects, the sea series in particular being enthusiastically received. Mr. Acres referred to experiments made some time ago in the same direction by Mr Friese Greene, but stated that his own apparatus was of a different nature to Mr. Greene's, and was the outcome of many years' work.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

JANUARY 9,—Mr. J. J. Briginshaw in the chair.

Mr. Percy C. Fox was unanimously elected a member of the Association.

DARK-ROOM ILLUMINATION.

Mr. Bayston passed round two negatives, exposed in three portions, for five, ten, and fifteen minutes respectively, one to a dark-room lamp (having a yellow glass and a thickness of orange paper) at twelve inches distance, and the other to a candle at twelve feet distance, having a piece of card interposed to cut off the direct rays, the reflected light only reaching the plate. The results showed that more fog was present in that exposed to the lamp than that exposed to the candle.

The CHAIRMAN remarked that it had been proved before that one could develop by the light reflected from a wall quite safely. He was in the habit of sheltering the candle with a square sheet of yellow paper when away.

Mr. R. BECKETT, when absent from home, always utilised a candle for changing, placing it in the extreme corner of the room, and in this way had used some of the fastest plates on the market.

BACKING PLATES.

Mr. R. P. DRAGE thought it was high time that plate manufacturers issued them ready backed. It would be a great convenience.

Mr. J. E. HODD said that they were obtainable now. Messrs. B. J. Edwards & Co., and, he thought, Mawson & Swan, issued backed plates, but he did not know the constitution of the backing.

The HON. SECRETARY had used one recommended by Mr. Alexander Cowan, consisting of aurantia in collodion, which was coated in the usual way on the back of the plate. He asked if much expense was attached to the grinding of glass by the sand-blast process commercially, so as to cause a much higher price for plates with a ground-back surface. He referred to the advantages to be obtained in working up a negative. It was suggested that it could be done by hydrofluoric acid, but

Mr. TEAPE thought the action of the acid was uneven, unless the glass was scrupulously clean.

ELEMENTARY EVENINGS.

Mr. J. E. HODD, referring to the scarcity of definite subjects for the meetings, proposed, "That one night a month should be set aside for practical demonstrations on matters concerning photographic practice, embracing more or less elementary matters." He thought it would prove some encouragement for the younger members, who would not get much benefit from the scientific discussions.

Mr. TEAPE was opposed to the idea of setting apart definite evenings for elementary subjects. The shilling handbook supplied all necessaries in this respect.

Mr. R. CHILD BAYLEY thought open evenings were the best, and that a Society like the London and Provincial should not go in for subjects which were amply provided for by the local Societies, of which nearly every member of the London and Provincial were members also.

The HON. SECRETARY thought that the treatment of the subject, even though elementary, greatly affected the question. If treated in the proper way, elementary subjects should not be derogatory to the Association.

Mr. R. BECKETT agreed with Mr. Bayley *re* open evenings, but considered one could have too many of them.

Various amendments were proposed, but, on proceeding to vote, both the proposition and amendment were lost. The immediate result was that some dozen promises of papers or demonstrations were secured by the Secretary.

THE TRAILL TAYLOR MEMORIAL.

The HON. SECRETARY stated that, having failed in obtaining further portraits of the late Mr. Traill Taylor to select from than those already submitted, he proposed that that sent by Mr. Hay Taylor should be accepted. This was agreed to, and a carbon print decided upon by show of hands.

Mr. A. MACKIE drew attention to the fact that, through the death of Mr. Traill Taylor, the Association had lost one of its trustees, and urged that the vacant office be filled at once.

It was proposed by Mr. DRAGE, seconded by Mr. FRESHWATER, and carried, that Mr. A. Haddon be appointed the second Trustee; and, in order to fill the vacancy so formed in the curatorship, Mr. MACKIE proposed, and the HON. SECRETARY seconded, that Mr. Grundy be entrusted with this office. This was carried.

Messrs. HADDON and GRUNDY briefly replied.

It was announced that the Committee appointed to arrange for a suitable memorial to the late Mr. Traill Taylor had decided to institute a lectureship to commemorate his name. The lectures would be delivered either in London or in the provinces, as decided by the management, which would be composed half of London men and half of provincial men. Subscriptions are to be sent to the Hon. Secretary of the Committee, Mr. A. Mackie, 3, Upper Baker-street, N.W.; but the Hon. Secretary of the London and Provincial would collect the subscriptions of its members.

PHOTOGRAPHIC CLUB.

THE weekly meeting of the above Club was held at Anderton's Hotel, on Wednesday, January 8, Mr. Frank Haes in the chair. The Judges in

THE WATKINS' DEVELOPING COMPETITION

(Messrs. F. A. Bridge and J. B. B. Wellington) reported that they had awarded the first prize of four guineas to Mr. B. J. Edwards, and the second prize of two guineas to Mr. Ben Edwards for their respective entries. Although upwards of 100 entry forms had been applied for in this competition, the actual competitors amounted to seventeen only. Of this number some had not adhered to the rigid conditions laid down, and many of the competitors had adopted the method of cutting a plate, exposed upon an ordinary landscape subject, in half, and developing the separate moieties. The Judges were of opinion that no fair conclusion could be arrived at from this latter method. The successful entries appear to support the oft-reiterated statement made by practical photographers that an alteration in relative gradation can be effected in the course of development.

Since the last meeting of the Club, Mr. COWAN had measured Messrs. Edwards's negatives in the photometer, and had charted his results. He stated, as the conclusion which he drew from these measurements, that the portion of the plate which had received normal development might be called a perfect negative, that is to say, that the gradations represented the light values as given by exposure. On the other hand, the half of that plate which had been abnormally developed did not appear to be a true negative at all, and he suggested that, owing to the presence of a very large amount of alkali in the developer, there had been a solvent or reducing action upon the sensitive film. That portion of the plate normally developed represented an exceedingly good scale of gradation, and showed that the plate employed had a long period of correct representation. On the other hand, the curve in the abnormally developed plate possessed no portion which could be said to have a period of correct gradation.

Mr. EDWARDS, in the course of some remarks, expressed his opinion that, if the very rigid conditions laid down by Mr. Watkins had been somewhat modified, he would have been able to demonstrate still better than he had done that gradation could be controlled and altered by development, and he said that he had made exposures varying as much as twenty-four to one, and had from these very widely different exposures produced negatives which he himself could not tell apart, and the prints from which could not be distinguished from one another.

Mr. ALFRED WATKINS said that the question was so large that no single competition could be expected to produce a conclusive result. His idea had been to compare different developers on fixed lines, and this accounted for what Mr. Edwards had described as "rigid" conditions. His object was to compare one factor at a time, and so he endeavoured to eliminate all considerations of fog and time of development. He hoped that some endeavour would be made to follow up and utilise the information which could be gained by analysing the results of the competition. Were, he asked, the variations which Mr. Edwards had produced due to modification in the use of pyro, bromide, or alkali? His own experiments tended to show that the only factor with which he could produce modifications was the use of bromide. It was with him a question of some bromide or none. He should also like to know if any of the competitors had relied upon tentative development—by which he meant, the adding of further supplies of alkali from time to time during development?

Mr. SINCLAIR said that the suggestion of a solvent or reducing action of a highly restrained developer, whether due to the presence of a large quantity of bromide or alkali, seemed to him to be a new feature, and to present a field for careful investigation.

Mr. FRY expressed a hope that the Judges would make a written report of the facts as they had found them; he could understand and appreciate the objection to make a statement upon so highly controversial a subject, but he thought that a brief statement of the facts as they found them would be of value.

Mr. SINCLAIR advocated the point, and the Judges agreed to make a written report.

Mr. HAES said that the photographic world was indebted to Mr. Watkins for his efforts to elucidate the question, and, at his suggestion, the members passed him a very hearty vote of thanks; a similar vote was also passed to the Judges.

Mr. Foxlee showed a model of a camera front, which had been made by Mr. Hare for the late Mr. T. R. Williams. The model, which was perhaps thirty years old, included all the salient features of a new patent camera which had been recently exhibited at the Club, and illustrated the adage that there is nothing new under the sun.

THE INFALLIBLE HAND CAMERA.

A member showed McKellen's Infallible hand camera. He explained, by means of a working model of the camera, from which one side of the case had been removed so as to expose the working parts, the simple process by which the plates or films (for either can be used, independently or together) are changed. The act of changing consists in turning a thumb key forward about one full revolution, and then turning the key back to its original position, and until a click can be distinctly heard. The plates or films, which are fitted into sheaths, are made to fall forward by a mechanical device which does not depend upon gravity, and by part of the same device the plates are firmly gripped in position after they have been pushed forward, so that they cannot shake or rattle. An ingenious self-locking door at the bottom of the camera is the means by which the exposed plates can be removed, and an automatic indicator can be fitted to show how many plates have passed. The exposing shutter is of a simple character, and, being made of metal, principally aluminium, appears to be fitted to stand considerable wear and tear. A self-closing shutter is fitted to the lens, which automatically closes when the front of the camera is opened, so that it is impossible to fog or spoil a plate by accident. The Heywood finder, although not an integral part of the camera, can be fitted to it, and is a simple mechanical device without optical complications, by which the precise amount of the view falling upon the plate can be readily ascertained. As the camera has to be raised to the level of the eye to use this finder, photographs taken by its aid represent more truly the actual perspective than do others taken at a lower level altogether. The Infallible hand camera appeared to create a favourable impression upon those who saw it.

MANCHESTER PHOTOGRAPHIC SOCIETY.

JANUARY 9,—The President (Mr. H. M. Whitefield) in the chair.

Mr. BROTHERS drew attention to the recent

REMARKABLE DEVELOPMENT OF PHOTOGRAPHY

in connexion with the discovery of a German professor in photographing by the aid of the light force obtained from an electric current passed through a vacuum tube, whereby certain substances, ordinarily opaque, are rendered practically transparent to the actinic rays, as when overlapping strips of tinfoil were photographed on to a dry plate as if they had been semi-transparent. In another instance, a photograph of a human hand exhibited the actinically opaque skeleton, which was photographed through the flesh of the hand, the flesh only presenting an appearance similar to halation. This discovery is still in an early stage, and much is expected of it when further investigated.

Mr. H. SMITH gave a description of his process of

PHOTO-CRAYON

for positive prints. He first prepares a gelatino-chloride print by stripping from finely ground glass, which gives a slightly rough surface, and then retouching the print thus obtained as he would retouch a negative, only using coloured crayons kept very sharp. Faber's or Hardtmuth's pencils in cedar were found the best, and can be had in almost any colour. The colouring should be done very lightly with a slight circular motion, being careful not to block the detail, so that the work will form a delicate stipple. A jug is then filled with hot water, and the print is held face downwards over the steam, which will soften the gelatine and make the colours fast, being careful not to steam too much, or it will approach in character to an enamelled print, which is not desirable. The print can be left as it is, or stripped from plain or ground glass or flashed opal by the aid of sheet (bon-bon) gelatine, which is cut a little smaller than the print, soaked in water, and laid on the plate; the print is then placed in contact, and all air bubbles forced out; it is backed with stiff paper, and, when quite dry, stripped and mounted in any suitable manner. Mr. Smith showed some flower studies by this method, the prints having the appearance of delicate water-colour drawings.

Mr. F. EDWARDS read a paper on his method of

INTENSIFYING GELATINE DRY PLATES.

Many photographers have an aversion to intensifying their negatives when too thin to give satisfactory prints, and they try to get over the difficulty by printing in a weak light or through coloured glass. He (Mr. Edwards) never scrupled to strengthen his negatives when necessary, and by these formulæ never had a case of fading, or the negatives altering at all by keeping:—

A.

Perchloride of mercury	50 grains.
Potassium bromide	50 ,,
Water	10 ounces.

B.

Nitrate of silver	50 grains.
Potassium cyanide (pure crys.)	50 ,,
Water	10 ounces.

After the negative has been well washed to free it from hypo, bleach in A, and, after another good washing, proceed to darken in B. Mr. Edwards thought that this bleaching gave a purer white than the plain mercury solution, and solution B gave a good blue-black. In many cases the negative only requires slight intensification, in which case the bleaching need not be carried to any extent; and Mr. Edwards's method is to bleach the negative in the proportion of density required, it being a fallacy to always whiten through to the back of the negative.

Mr. Edwards then gave a practical demonstration of the process, cutting a stereoscopic negative in two, and intensifying one half, when the two were compared; the one treated was greatly improved.

Mr. A. E. CASSON gave a demonstration of

COLLODIO-CHLORIDE PRINTING,

introducing the subject with a few remarks. The process was invented in the year 1865 by Mr. Wharton Simpson, and for some years secured a good deal of attention; but, owing to various practical difficulties in making the paper on a small scale, combined with the high cost of production, it gradually fell into disuse. Collodio-chloride emulsion consists of silver chloride in collodion in a very fine state of division, and the excellence of the paper lies in the definite and stable character of the silver salts and the thinness and non-absorbent character of the film. The chief characteristics of the paper are: Purity of the whites, ease of toning, absence of double tones, evenness of toning, and quick drying. The paper which Mr. Casson put before the meeting was the Paget C.C. paper, both smooth and matt surface, and in his hands it had acted most satisfactorily, and left nothing to be desired, in his first four dozen not having one failure, either by cracking, curling, or blistering. A great deal depends on observing the instructions laid down for this paper; for instance, by keeping the paper between weighted boards in a cool place (or alum before toning) does away with all cracking and peeling, while blistering is generally caused by an over-strong hypo bath.

Mr. Casson then proceeded to tone prints in the Paget platinum bath, any tone being obtained at will, from a rich sepia to a perfect platinum black, and, by the interest evinced by the members, and the packets of paper distributed, there should be a fresh impetus given to this the most promising of photographic printing processes.

Brixton and Clapham Camera Club.—The Seventh Annual General Meeting took place at Brixton Hall on the 7th inst., Mr. J. W. Coade (President) in the chair.

THE REPORT OF THE COUNCIL

was read, from which it was evident that great progress had been made during

the past year, no fewer than thirty-two new members having been elected, the effective numerical strength of the Club being eighty. The Council noticed with regret the resignation of the Presidency in June last by Dr. J. Reynolds, who, owing to professional engagements, had been compelled to relinquish this office, which he had held for three or four years, during which he had spared no efforts to promote the interests of the Club, of which he still remains a member. Mr. W. H. Harrison, a gentleman well known in the photographic world, who joined the Club in April, 1892, and had always placed his valuable and extensive technical knowledge at the disposal of the members, had also been compelled, through continued ill health, to resign his office as a Vice-President. The report stated that the fifth Annual Exhibition in March last was the most successful hitherto held by the Club, the Members' Class showing a large increase in the number of exhibits and quality of the work, and the Open Class (the first in connexion with the Club's Exhibitions) obtaining entries from many of the most successful photographers of the day. The autumn session was opened with a *conversazione* on October 11 last, when about 250 members and friends attended. A number of interesting papers and demonstrations, covering a wide range of photographic subjects, have been given at the ordinary meetings of the Club throughout the year, and the appreciation of them was shown by the good attendance of the members on these occasions. The report concluded by drawing attention to the improved financial position of the Club, and urged upon the members the importance of their individual efforts to ensure its future prosperity. The report was unanimously adopted, and a cordial vote of thanks passed to the President, Council, and other officers for the manner in which they had performed their duties during the past year. The meeting also passed a unanimous vote of thanks to the photographic press for their notices and reports of meetings during the year. The following were elected as officers for 1896:—*President:* Mr. J. W. Coade.—*Vice-Presidents:* Messrs. W. Fraser, Horsley Hinton, W. Thomas.—*Council:* Messrs. C. F. Archer, M. Atkinson, J. Gunston, J. Price, R. G. F. Kidson, and G. W. Welham.—*Delegates to Affiliation of Photographic Societies:* Messrs. E. Dockree, W. Thomas.—*Auditors:* Messrs. F. P. Knights, T. F. Osborn.—*Lanternist:* Mr. R. G. Mason.—*Librarian and Curator:* Mr. W. H. Stoneman.—*Recorder:* Mr. A. Whittaker.—*Secretary:* Mr. F. W. Levett, 11, Corrance-road, Brixton, S.W.—*Assistant Secretary:* Mr. W. G. Dean.

Croydon Camera Club.—The meeting on Wednesday, January 8, was devoted to the consideration of the practical value of

ISOCHROMATIC PLATES.

The subject was handled by Mr. G. R. WHITE in an able and exhaustive manner, and thoroughly appreciated by the crowded gathering of members assembled. By means of a long series of experiments, the main results of which were shown upon the lantern screen, Mr. White, amongst other things, established to the satisfaction of his audience that ordinary plates will, providing a full exposure be given, yield results in colour-rendering not inferior to those of isochromatic ones; further, that the improvement in colour-rendering possible with an isochromatic plate is not exhibited unless a prodigiously dark screen be used, and exposure be given several thousand times longer than is needful with an ordinary plate used without a screen. The colour modifications produced by interposing screens of yellow, orange, green, and blue were contrasted, and the curious fact brought out that the relative values of coloured discs are strikingly changed according to whether the discs are photographed against a white or a black background. At the conclusion of a lecture which was followed with close attention, the President called upon Mr. SANDELL, who maintained that in practice the ordinary was as good as an isochromatic plate, except that, used with a screen, the ordinary required a much longer exposure. He also showed three prints of the stained-glass windows in the Livery Hall of the Goldsmiths' Company, which appear to have their colours rendered with accurate tonality. These were taken upon a double-coated Sandell plate, a screen being used equivalent to a No. 3 Ilford screen, exposure being one hour, *f*-22, mid-day in May. Others joining in an animated discussion were Messrs. S. H. Wratten, A. W. Hirst, J. Smith, A. E. Isaac, Watson, and Rogers. In moving a vote of thanks to Mr. White, the PRESIDENT referred to the extensive utilisation by a well-known French firm of photographers of isochromatic collodion plates, which they found to give far better results than the gelatine plate. Mr. SANDELL, in seconding the vote, stated that his experiments pointed to the fact that the most effective of all-colour sensitive plates was a slow lantern plate, dipped in erythrosine. Mr. WHITE, in acknowledging the thanks, explained that the superiority of collodion did not so much lie in being more amenable to colour-rendering, but that its grain was finer, and that it lent itself to a much greater degree of intensification than does a gelatine negative. Messrs. Waghorn and F. W. Kent were elected members.

Hackney Photographic Society.—January 7,—The President (Mr. E. J. Wall) in the chair.—After the preliminary business a very lucid lecture and demonstration on the

SPEED OF A PLATE

was given by Mr. R. CHILD BAYLEY. The lecturer traced the progress of the attempts made to get at some reliable method of measuring plate speeds from Hunt's book, which appeared early in the fifties, down to the investigations of Messrs. Hurter & Driffield only recently. The instruments of Warnerke and Spurge respectively were described, and finally Messrs. Hurter & Driffield's methods, Mr. Bayley giving a very complete account of their experiments and results.

Putney Photographic Society.—At the meeting on the 7th inst. Mr. JOHN A. HODGES gave a paper on

ENLARGING.

After referring to the principles on which all enlargements were made, Mr Hodges raised the question as to whether results could be produced by enlarging equal in quality to direct work, and answered it in the affirmative if artistic results were considered, and, in a more limited sense, said the answer would be the same from a technical point of view. Hard, wiry, biting definition in pictures of large size was to be avoided. There was something, difficult to define in words, which often stamps an enlargement as such. This is more evident when an enlarged negative has been made and a print taken from it on the glossy surface papers so much in vogue. The different lights available for enlarging were described by the lecturer, and the incandescent gaslight strongly recommended. A good portrait lens or a lens of the Euryscope pattern were stated to be the best when using condensers. The most suitable negatives for enlargement are those inclined to thinness, free from fog, and having a full range of gradation; such negatives are obtained by giving generous exposure and using well-diluted developer. If pyro is employed, one grain to the ounce will be ample. In regard to the developer for bromide paper, Mr. Hodges has a decided preference for ferrous oxalate; next to this he recommends amidol. For the former, this is the formula:—Saturated solutions of sulphate of iron and oxalate of potassium; the iron to be slightly acidified with sulphuric acid, the oxalate with oxalic acid; ten per cent. solutions of bromide of potassium also required; solutions should be filtered. Procedure is as follows: Give a full exposure, and use weak developer, viz: Saturated solution of oxalate of potassium, 3 ounces; saturated solution of sulphate of iron, ½ ounce; ten per cent. solution of bromide of potassium, 2 or 3 drops; make the bulk up to 6 ounces with distilled water. The picture will be a little longer than usual in appearing, but, if properly exposed, will come up and attain density in great regularity, the operation being quite under control. Develop the picture a little darker than desired, as there is a slight loss in the fixing. When the picture is sufficiently dense, place in clearing bath of acetic acid, 1 drachm to 20 ounces of water. Drain off, and apply second quantity of same solution. This is done to get rid of the iron, which would otherwise degrade the high lights. After second acid bath, well wash print before fixing in freshly made hypo bath (hypo, 4 ounces; water, 20 ounces). After fixing, the prints should be well washed in running water. If development in amidol is preferred, the following is the formula used:—Sulphite soda, 1 ounce; water to 20 ounces; to each ounce add 4 to 6 grains of amidol in powder, and 5 to 10 drops of ten per cent. solution of bromide of potassium. The exposure must be more accurately timed than for the weak oxalate developer, and less exposure is needed. The bromide paper must always be soaked in water before applying the developer. The image will appear more quickly in amidol than in ferrous oxalate. It will be found easier, in case of error, to modify exposure rather than alter the strength of the developer. Hints on mounting, and framing, and preparing enlarged negatives concluded a most interesting paper. A short discussion followed, during which Mr. Hodges made still more contributions to the many valuable hints contained in his paper.

South London Photographic Society.—January 6,—Mr. Maurice Howell (Vice-President) in the chair.—Mr. HOWARD ESLER showed and described a very interesting set of 120 slides illustrating the scenery of county Antrim, Ireland, including views of Belfast, Larne, Portrush, the Giant's Causeway, Glenariff, &c. Slides were afterwards shown by Messrs. French, Gardner, Pickering, and others.

Woolwich Photographic Society.—January 9, Mr. W. H. Dawson in the chair.—After the election of four new members, the Society's new lantern, which has been built expressly by Messrs. Noakes, of Greenwich, was inspected and criticised. Several members had brought slides to be tested, this being a preliminary trial before the Exhibition (which takes place on February 27, 28, and 29) of both slides and lantern. The light given was pronounced excellent, a ten-inch focus lens being used, and some good slides were exhibited. A set of about fifty by Mr. J. H. Thompson, illustrating camp life at Aldershot, were well received.

Bath Photographic Society.—Under the auspices of the Literary and Philosophical Association, a *conversazione* took place on Friday, the 3rd inst., at the Royal Literary and Scientific Institution. The company was numerous, and included many leading citizens. The Bath Photographic Society filled the programme, the principal feature of which was an illustrated lecture on

"PHOTOGRAPHING INSECT LIFE,"

given in a popular style by Colonel Linlay Blathwayt. Some very perfect illustrations were given by the aid of the lantern. Numerous photographs, direct and of large size, as well as bromide enlargements, were displayed about the hall, all of which had been prepared by Colonel Blathwayt for this lecture. Seldom has such painstaking and skilful work in this branch of photography been shown. In addition to the foregoing there was a general display of members' work on the walls and tables. The President of the Photographic Society (Mr. Perren) showed enlargements in carbon and a fine series of Scotch views. Mr. George F. Powell sent enlargements and some fifty prints in various styles, illustrative of last season's work, mostly film work. Mr. E. J. Appleby's exhibit was the most prolific. Frenagraph and pocket Kodak sizes were chosen, and these were illustrated by all-round printing methods. This gentleman also sent a frame of transparencies showing variety of treatment, and lantern slides printed by contact from pocket Kodak films. Colonel Sealey exhibited a frame of transparencies, also an enlargement, and contact prints. Mr. Ernest Lambert showed framed specimens of portraits, large heads direct, also Frenagraphs. Rev. E. A. Purvis sent several enlargements from quarter-plate snap-shots. Dr. Norman contributed enlargements, and direct prints of antiquarian interest from film negatives. Mr. Austin J. King showed Frenagraphs and stereographs. Monsignor Williams gave illustrations of snap-shot work with the stereographs from cut films. The Hon. Sec. (Mr. Middleton Ashmau) showed examples of interior and exterior work done at the excursions. After tea there was an exhibition of lantern slides, nearly all of the foregoing members contributing. Mr. Perren presided, and Mr. Appleby conducted the lantern arrangements. At the close Mr. T. F. Plowman, Chairman of the Literary Association, cordially thanked the members of the Photographic Society, and expressed a hope that there would be at least one evening of the kind each year the Societies existed, the very large attendance indicating unmistakably the popularity of these evenings. The lecture was illustrated by fifty

LANTERN SLIDES MADE FROM PHOTO-MICROGRAPHS.

After giving a definition of an insect, the lecturer explained that its body forms a kind of long sac or tube, in which there are a series of constrictions dividing it into a number of apparent segments, and that the portions between

these conatrictions are more or less thickened and hardened, giving support to the muscles, so that, while we have our skeleton inside our body, the insect has its body inside its skeleton. Photographs of the mouth organs of a beetle, fly, flea, plant bug, and other insects showed the very different forms the mouth organs assumed, according to the different purposes they had to serve. A number of photographs illnstrated the structure of the eye. Among Invertebrates are two types of eye, simple and compound. Simple eyes may consiat of a mere pigment spot, or may increase in complexity to something approaching the structure of the human eye, which was described somewhat fully, and it was explained how the simple eyes of insects perceive objects much as we do; that is to say, a reversed picture is thrown on the expansion of the nerve endings. In the compound eyes the whole principle is different; here the surface of each eye is divided into a number of facets, the article of each forming a minute lens, the number of facets varying from a very few in some species of the ant to four thousand in the house fly, and twenty-five thousand in some beetles. A section was shown through the compound eye of a fly. In this case each facet was an outer cover like a watch glass, forming the cornea, beneath which came a lens, and then a crystalline cone, the point of junction of lens and cone surrounded by pigment cells as an iris, the cone connected with the retina by a transparent rod. In the case of the compound eye, the insect sees the actual object, and not its reversed image. Several photographs were shown of portiona of eyes with facets, both hexagonal and square, one showing the image of the lamp flame in each facet. An account was given of the structure of a fly's foot, also of the spiracles and air tubes. Several slides were devoted to insect parasites, acari from the house fly, &c., and also of double parasites, such as a mite parasitic on a beetle, with a small acarus parasitic on itself, showing that there is at least a foundation for the well-known lines:—

"E'en little fleas have other fleas
Upon their backs to bite 'em;
And these, again, have smaller fleas,
And so *ad infinitum*."

Some examples were shown of objects taken by reflected light—eggs of butterflies, and some of the eggs of the stone mite, which sometimes appear in immense numbers in a single night in places where they have not been seen before for years. The lecturer ended by saying that photo-micrography was a pursuit that could be taken up by any one possessing a microscope and a camera, requiring no special apparatus, so long, at least, as only simple low-power work, such as had been shown that evening, was aimed at; but that here both original and useful work might be done by any one. One was independent both of season, time, or place; if you could not go out of doors, objects might be found in the house from which faithful pictures might be made of that on which, very likely, no human eye had ever gazed before, or, if it had, of which no record had been left.

Bradford Photographic Society.—January 9, Mr. R. J. Appleton in the chair.—Mr. W. Harmsworth, of Bradford, gave his very interesting lantern lecture, entitled

A Tour to the Isle of Wight, London, and the South Coast.

A number of very good slides illustrating the journey were thrown on the screen, and the lecture was greatly enjoyed by a large number of members. The Society's own lantern was used for the first time, and was manipulated by Mr. E. Harmsworth. The lantern was presented to the Society by Mr. F. J. R. Sutcliffe, and the nine-foot square Crystal Palace opaque screen by Mr. Percy Lund, two of the Vice-Presidents of the Society. To both of these gentlemen the Society tenders its sincere thanks for their kindness in presenting these two most useful and essential articles.

Liverpool Amateur Photographic Association.—January 9.—Mr. R. Talbot Kelly, R.B.A., gave a lecture on

Egypt and the Arabs.

The lecturer, passing quickly over the ground traversed by the ordinary tourist, dealt chiefly with the lesser-known parts of Egypt, and described the habitations, customs, and manners of the native population in parts removed from European influences. He also gave a realistic account of his visit to the Bedouins or Arab tribes of the desert, with whom he remained some time, making innumerable sketches of these picturesque, roving people, to be worked up into pictures upon his return to England. The lecture, which throughout was of a highly interesting nature, was illustrated by a number of lantern slides, some of which were direct photographs, others being photographic reproductions of paintings by the lecturer.

Sheffield Photographic Society.—January 6.—The chair was occupied by Mr. Tomlinson, and a new member elected. A set of slides, illustrating the Rivers and Broads of Norfolk and Suffolk, lent by the Great Eastern Railway Company, were thrown on the screen, the lantern being ably manipulated by Mr. J. W. Charlesworth, the descriptive portion being given by Mr. S. Camp, to each of whom a hearty vote of thanks was accorded, as also to the Manager of the Great Eastern Railway Company for loan of the slides.

FORTHCOMING EXHIBITIONS.

1896.	
February 27-29	Woolwich Photographic Society.
March 2-6	*South London Photographic Society. Hon. Secretary, Charles H. Oakden, 30, Henslowe-road, East Dulwich, S.E.
3-6	*Cheltenham Amateur Photographic Society. Philip Thomas, College Pharmacy, Cheltenham.

* Signifies that there are Open Classes.

Correspondence.

PAPER NEGATIVES.

To the Editors.

Gentlemen,—Will you allow me to add some words to the letters published in The British Journal of Photography, on December 13 and 27, about paper negatives. I did not read the discussion published before, but I adhere absolutely to the opinions of the two letter-writers. The spools of paper coated with negative emulsion are the best things for photography at home and abroad. Since I got acquainted with the negative paper of the firm Morgan, at Richmond, I have employed it in several roll-holders, and even cut in sheets in ordinary dark slides, up to the size of 18×24 c.m. (the French whole-plate). The emulsion keeps perfectly on the support paper, before, or after exposure, the development is quite easy, and one gets excellent negatives without a trace of halo, be it from a window in an interior or from the sun-lighted sky in a landscape, where the tops of the trees show often traces of halo on a glass negative.

I generally develop twenty-four negatives of drawings or printing types (which are my *spécialité*) at once in an old hydroquinone bath, and they are very good, quite black and white. For portrait or landscape I prefer our old friend pyro-soda, which gives detail and intensity at will. After washing, I squeeze the negatives on metal plates (ferrotype), and the surface of the negative is as even as a glass plate, and gives excellent prints without the grain of the paper. The only drawback of this excellent method is the want of transparency of the paper, which lengthens the printing, and renders it difficult in winter. But still I prefer it to glass plates, both for its lightness and its cheapness, notwithstanding its excellent results. In latter times I sometimes, for cut sheets, use celluloid films, which are better than glass plates, but are still inferior to paper.

If several of the good firms would make proper spools I am sure the amateurs would be tempted to try and then to adopt them. Perhaps some chemists would then try to find a method for rendering the paper translucid, and there is no doubt they would find it if they willed it.

Paris, le 8 Janvier, 1896, 30 *rue Blanche*. Marie Pellechet.

P.S.—Without mentioning the landscape architecture negatives, I have made about 2000 paper negatives, 13+18 c.m. of drawings, so you can see that I have a certain experience of the paper.

USE OF THE SWING BACK.

To the Editors.

Gentlemen,—I returned last week from a southern tour, and on reading the back numbers of your Journal, to which I have been subscriber for the last ten years, I find in your No. 1850, of October 18 last, an article on the use of swing back. This article is based upon a process which I originated last autumn, and which I published in the *Bulletin* of the *Association Belge de Photographie*, Nos. 8 and 9, August and September, my article is dated September 9, entitled "le Redressement des Lignes," and this number of the *Bulletin* was posted on September 15 and you received on the 16th as usual in exchange with your good paper.

My above article, with specimen and diagrams, has been reproduced or resumed by a great number of the photographic journals, for instance, *Photographisches Central Blatt*, No. 3; *Photographische Mittheilungen*, No. 16; *St. Petersburg Photographic Journal*, No. 10; *Photo Gazette Paris*, No. 12; *Bulletin de la Société Photographique*, No. 9, all dated October, and they all mentioned my name and the origin, in connexion with the process, your Journal being the only exception.

It is true, your article extends beyond the particulars given by myself in the articles, but your second paragraph of second column shows clearly that the base of process is the one given by me, namely, the combined inclinations of the negative and the positive sensitive tissue. It is not a considerable matter to find this, but something new always takes a considerable trouble to be found out, and, when publishing the result, it is but a small compensation if our name be published in connexion with same.

I feel certain it is also generally your habit to name in your Journal the origin of the articles or processes you publish, and that it was on this occasion an oversight if it was not done.

I should be glad to learn if this is so, the more as I have other novelties relating to stereoscopic photography which I might shortly bring under notice.—I am, yours, &c., Victor Selb.

45, *Avenue Moretus, Anvers, January* 6, 1896.

The above letter has been forwarded to the writer of the article in question, who replies as follows:—

"This is a very curious instance of two writers travelling almost simultaneously over the same lines, but you can assure M. Victor Selb that the article he refers to was not inspired in any way by his communications to the Belgian journal, as neither at the time it was written nor up to the present have I seen his article nor any of the re-

productions or references to it. What I wrote was purely from work actually in hand at the time, and was scarcely put forward as presenting any novelty to ordinary photographers except in as far as I wished to demonstrate that for enlarging purposes, in order to secure the very highest class of results, it is better to avoid the use of the swing back *in taking the negative*. I do not know, of course, the general tenour of Mr. Selb's article, but I judge from the reference he makes to mine that he attaches importance to the swinging the negative and sensitive plate in contrary directions so far as swinging the negative or proof to be copied is concerned; it has, of course, been known to every one that sloping perpendiculars can be corrected by this means, and, in order to secure sharpness in the copy, it is such an obvious and necessary corollary that the sensitive plate or surface be swung in the contrary direction, that I really cannot say whether or not it is a matter that was or was not known generally. I merely mentioned these two points as being absolutely necessary to perfection in result, and, if there was anything "novel" at all in the article, it was the formula for calculating the position in which the negative must be placed in order to secure at once accuracy of lines as well as absolute sharpness. It may also be new to many that an absolutely better result can be secured under such circumstances by tilting the camera as much as may be necessary, and letting the swing back and sliding front alone when the negative is taken, and doing what is required to secure perpendicular lines when the enlargement is made."

STEREOSCOPY ON THE SCREEN.

To the EDITORS.

GENTLEMEN,—In the paper by Mr. Freshwater, given before the London and Provincial Photographic Association, and published in the JOURNAL last week, he commences by claiming that his method of obtaining a stereoscopic effect on the screen has not been shown before in this country. If I understand the method correctly, I think that it has. At the Wolverhampton Free Library Science Students' Soirée some years ago, I assisted Mr. W. Whitehouse, F.C.S., to give an entertainment by a similar method. We used an ordinary biunial lantern and limelight.

A square of specially selected red glass was placed behind the slide in one lantern and a specially selected green behind the other. A slide from one half of the stereoscopic negative was placed in one lantern (illuminated by red), and a slide from the other half of the same negative in the other lantern (illuminated by green), the two pictures being thrown nearly coincident on the screen. They were viewed through a pair of spectacles prepared with similar red and green glass to that used in the lantern, an audience of about a dozen being accommodated at once, as we only had that number of spectacles.

There was a little difficulty in getting the "effect," and I discovered afterwards it was due to the two objectives being of slightly different focus.

The exact date I cannot give from memory, and I have not the programme up here (I can obtain one), but it is at least four or five years ago, I should say.—I am, yours, &c., T. W. DERRINGTON.

12, *Guildford-road, S.W., January* 13, 1896.

DR. EMERSON AS A NOVELIST.

To the EDITORS.

GENTLEMEN,—In your kind and prominent comments upon Dr. Emerson's latest book, *Marsh Leaves*, your critic suggests that, were Dr. Emerson to devote himself to fiction, he might do for East Anglia what Mr. Hardy has done for Wessex, and Mr. Blackmore for the west.

May I point out that Dr. Emerson has already produced several works of fiction, notably, *A Son of the Fens*, *English Idyls*, *East Coast Yarns*, *Tales from Welsh Wales*, and *Signor Lippo*, all of these works having received the best of notice from the best literary papers, *e.g.*, *Saturday Review*, *National Observer*, *Athenæum*, &c., and some of the very best and most distinguished men claim that some of them 'belong to literature!' Further praise is not needed.

I assume your critic is not a student of general literature, and, as such works as the above are not sent to the photographic press for review, he has missed them. Trusting that this may lead him and others to the books themselves, books that are caviare to the public and people of school-board education.—I am, yours, &c., LITERATURE.

THE PHARMACEUTICAL SOCIETY.

To the EDITORS.

GENTLEMEN,—As one of those who, by agitation in the trade press (three or four years ago), did something to stir up the Pharmaceutical Society to take action against unqualified tradesmen, I may be allowed to say that I never imagined that Mr. Hume would find himself in the position of "defendant." For my part I always conceived him to be "one of the fraternity," at the same time I knew (and know still) of similar illegalities in high places.

I certainly consider all the sympathy expressed for Mr. Hume *ill-considered*, except, of course, from a personal point of view.

Mr. Hume says, I think, that he has been in the trade thirty years. What trade—that of an optician? I have been in Mr. Hume's shop some years ago, and it certainly looked to me uncommonly like that of a chemist and druggist. Be that as it may, he must have been perfectly well known the powers conferred upon the Pharmaceutical Society, and the exceptions allowed, which might possibly have brought Mr. Hume into line with the great body of pharmacists, had he cared to entertain the idea.

I entered the trade twenty-seven years ago, and, as my certificate is dated 1873, it will be seen that the examination was no stiffer than a person of average intellect could pass. Why could not Mr. Hume have done the same, knowing, as he must have done, of the existence of the Pharmacy Act of 1868?

My recollection is that the trade in photo-chemicals was at the time (1868) of a very limited character. In the town where I was apprenticed, *an optician* certainly did something in it. I knew him quite well, but I knew also that one of the chemists (and druggists) also made a speciality of photo-chemicals, and such pure reagents, &c., as are required by analysts, &c.

In another large town in the West of England, I know for a fact that one of the chemists there did the bulk of the trade in the apparatus and chemicals, &c., then used by the old wet-collodion workers. I was an assistant there, and saw and heard many indications and reminiscences of those old days. Going north, we know that Mawson & Swan have been from the first connected with pharmacy. Many similar cases could, no doubt, be found, proving that, *all along*, the sale of these goods has been for the most part in the hands of chemists and druggists, or men who were at some period of their lives connected with the drug trade.

Many of the statements made in the letters of your correspondents are, on the face of them, exaggerations, to say the least. It is inconceivable that a person who has had to pass a stiff examination in chemistry (see the present minor syllabus), including analysis, and who must have spent some months at least in a properly qualified laboratory (where the necessity for purity, and so on, of all reagents used would be impressed upon him), should, when in business for himself, deliberately supply any article for analytical purposes *impure* and *unfit* for such use. It is a well-known fact, that in most towns of any size there is *one* chemist and druggist who appears to be *the* man who lays himself out for the supply of chemicals and reagents, and to whom doctors, and chemists, &c., go when they want such goods. Run over a few towns, and the names of these men come naturally to the lips: Newcastle-on-Tyne, Mawson & Swan, or Brady & Martin; Leeds, Reynolds & Branson; Cheltenham, Thomas or Beetham; Leicester, Joseph Young; Great Yarmouth, Wm. S. Poll, and so on.

Many of your readers may have an idea that the profits of the druggist are *enormous*. Tell them that we pay 9*s.* 3*d.* per dozen for Beecham's, and sell at 9½*d.*; 11*s.* 6*d.* per dozen for Seigel's, and sell at 1*s.*, to take two of the best known; and that stamped medicines—even the rarer sort—are all similarly "cut," and they won't believe you. Drugs and chemicals are all "cut" in the same way, and some amateurs expect even their developers at the bare cost of the contents. *Dispensing* charges are at least fifty per cent. lower than when I was an apprentice.

All that is conserved to us is the "poison schedule," and this is, as a rule, more trouble than it is worth. For my part, I don't keep half those on the list, and rarely supply the other half. It is not worth the risk, for the fact that due precaution has been taken doesn't prevent a man poisoning himself, and also is no safeguard against uncalled-for strictures (you have only to read some reports of inquests of late years) on the part of *coroners*, who *ought to be*, but are not, better informed.

The fact is, the agitation *in re* Mr. Hume, is little more than sympathy with an undoubtedly clever and (morally) qualified, *but unregistered*, man. But who's to blame for that? I know several clever and good fellows who are much in the same boat; one of them is as good as a full-blown M.D., but, somehow, he can't get through, and another has passed *at various times* all the subjects in the minor, but has never been able to do them all at the same sitting!

For my own part I practise dentistry, surgical and mechanical; but I should not do so, nor expect to be allowed to call myself a dentist, were I not qualified and *registered*.

It is quite true that things are very different to what they were twenty-five years ago. Various new industries have grown up, but it cannot be denied that the Pharmaceutical Society has, in the matter of *education*, kept *in the front*. Pharmacists or chemists and druggists are an educated body of men, and can do all that is required of them, with, of course, the usual exceptions, as in all trades and professions.

Alter the law if you like, and if it be necessary. Many chemists will support reform. But don't run away with the idea that there are heaps of "*fat*" in pharmacy.

I was once managing a business for a gentleman whose name stands exceedingly high in the estimation of photographers. He told me that he wished "me to have all I could make there in the way of profit, he was quite satisfied if he got enough out of it to pay for his gloves;" but I could only make 3*l.* or so per week, so hampered were we by unqualified grabbers.

However, I must bring this to a close, and, with apologies for the length of this letter,—I am, yours, &c.,

D. D.

ILLINGWORTH *VERSUS* DRAYCOTT.

To the EDITORS.

GENTLEMEN,—Kindly allow me, through the medium of your valuable paper, to tender my sincere thanks to the profession for their letters of sympathy in the loss of my recent action. It is something to know that there are others who have had precisely the same experience. I much appreciate the sympathy extended towards me.—I am, yours, &c.,

J. A. DRAYCOTT.

66 *and* 67, *New-street, Birmingham; Leicester-square, Walsall; and* 11, *Gold-street, Northampton, January* 14, 1896.

SOCIETY OF LADY ARTISTS' PHOTOGRAPHIC EXHIBITION.

To the EDITORS.

GENTLEMEN,—I enclose you a prospectus of the Exhibition of the Society of Lady Artists for 1896. As art photography forms one of the classes of exhibits, it may be of interest to your readers.

I may mention that George Davison, Esq., late Secretary of the Camera Club, and Lyonel Clark, Esq., are the Judges in the photographic section; and their names are a sufficient guarantee of the class of work which will be admitted.—I am, yours, &c.,

FANNY E. PARTRIDGE, *Sec.*

9, *Nottingham-place, W., January* 13, 1896.

[Particulars of the photographic section may be obtained of Miss Partridge at the address given.—EDS.]

Answers to Correspondents.

*** *All matters intended for the text portion of this* JOURNAL, *including queries, must be addressed to* "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 2, *York-street, Covent Garden, London. Inattention to this ensures delay.*

*** *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

*** *Communications relating to Advertisements and general business affairs should be addressed to Messrs.* HENRY GREENWOOD & CO., 2, *York-street, Covent Garden, London.*

*** *It would be convenient if friends desiring advice respecting apparatus, failures in practice, or other information, would call at the Editorial Office on Thursdays from* 9 *to* 12 *noon.*

LANTERN.—W. V. MORRIS.—If the figures be cut out and mounted on glass as a lantern slide, and used as such, they will be perfectly sharp when projected on the screen.

VEILING OF NEGATIVES.—BRAMDEAN. The veiling, when some of the negatives are treated with acid, is because, in the instances when it occurs, the negatives are not sufficiently washed.

PATENTS; CALCIUM CARBIDE.—GEO. PITCHER says: 1. "Can I make a patent for my own use in trade, not to sell? 2. Where can calcium carbide be procured."—In reply: 1. We presume you mean a "patented article." No. 2. Harrington & Co., 53, City-road, E.C.

AGREEMENT.—PRINTER. We cannot say if the agreement is a legal document or not from the data given. If it is, you can, of course, claim your salary, according to the terms of it, to the end of the term. You had better submit it to a solicitor if there is any dispute in the matter.

FACTORY ACTS.—UNCERTAIN and BRAMDEAN. We should opine that neither case comes under the Factory Acts; but the abstracts and notices supplied, of course, give the necessary information if carefully read. If there is any further doubt on the subject, apply to the Factory Inspector of the district.

PROCESS SCREEN.—L. E. N. S. Wire gauze, however fine, will not do in place of a properly ruled screen. Even for experimental work you should have the right thing, or you will not be able to judge how far your failures may be due to your manipulations, or to the make-shift appliances. Small screens are not so very expensive, after all.

STUDIO.—R. HOW.—The sketch shows a very good form of studio for all-round work, and the proportions are also good, except the length. If you can get another three or four feet, you will find it a great convenience at times. Twenty-three feet is a little too short for standing figures, full length, as it necessitates the use of lenses of shorter focus than is desirable.

SCRATCHED LENS.—S. CRESSY.—The only way to remove the scratch on the lens is to regrind and polish the surface. But there is really no reason to do this, as the scratch will do no harm at all in practice. The only thing is there is a *very* slight loss of light from the scratch, and nothing more. If you try the lens, you will discern no difference in its working.

OIL STOVE.—SEPTIMUS. The fumes from this will do no harm in the dark room. There should be no smell if the wicks are kept in good trim and the stove itself is kept clean. More smell arises from the oil outside the stove than from the wick. If the stove is wiped scrupulously clean in all parts, and the wick is in good order before it is lighted, there will be no smell from it, supposing, of course, that good oil is used.

DISTILLED WATER.—LEEDS says: "We have a steam engine always running, and I notice that from the exhaust pipe there is always a small stream, or series of drops of water. Is this not distilled water, the same as sold by chemists?"—It is distilled water, but highly impure, as it is contaminated with greasy matter from the engine. Such water would not do at all for photographic purposes. Tap water, however bad, would be better.

TONING DISCOLOURED PAPER.—R. W. C. If the paper is all discoloured to the extent of the sample sent, it will be quite impossible, with any toning bath, to get pure whites. Of course, there is always a risk in buying "job lots" at miscellaneous dealers'; moreover, you say that you have had it by you some months, hence it must be in a worse condition than when you first bought it. The only suggestion we can make is to throw the stuff into the waste basket.

VARNISH.—W. PAGE asks for a varnish that can be applied to the negative cold and will dry quickly. Such a varnish is made by dissolving dammar resin in benzole. No very definite proportions can be given, as different samples of dammar make a more viscous solution than others. Better make a solution of about thirty grains to the ounce, and then dilute it if too thick. Dammar varnish is not so durable, or will bear the same rough usage as a spirit varnish, with shellac as a base.

WOODBURYTYPE.—R. W. (Glasgow) writes: "Can you tell me where I can get Woodburytype blocks made from my negatives, and if a licence is required to print photographs by the Woodburytype process?"—We are not aware that any one supplies Woodburytype blocks to the trade. You might apply, however, to those who do Woodburytype printing, and ascertain if they do—the Woodburytype Company, or Waterlow & Sons, for example. No licence is required to do Woodburytype printing.

RESIDUES.—AGENT says: "I shall be much obliged if you will give me the best means of saving gold and silver residues."—To the washing waters of the prints add common salt or hydrochloric acid. The silver will then be thrown down as chloride. To the fixing baths add sulphide of potassium, which will throw down the silver as sulphide. To the toning bath add a solution of sulphate of iron. Collect the precipitates, dry, and send to the refiner. Keep the gold and silver residues separate.

WASHING PRINTS.—E. MITCHELL writes as follows: "In the directions sent out with the new printing papers we are told to wash the prints, after fixing, one or two hours, and not longer. Is that long enough? With albumen paper many do not consider the prints are sufficiently washed unless they have been in running water all night"—The time mentioned is long enough if the prints are attended to all the time; but, if they are merely left soaking in water, they will be insufficiently washed. Albumen prints can be as well freed from the hypo salts in a couple of hours as by an all-night's washing, that, is if the work is properly done.

STAINED BACKGROUND.—Y. Z. X. says "the rain got through the roof of the studio on to the background, and has made a stain right down the middle of it. Can you tell me of any means of removing it? It is done in distemper colour."—We are afraid we cannot say how the stain is to be got rid of except by recolouring it. If, at the time the water got upon it, the background had been made evenly wet all over, it would have dried without showing a mark. Sometimes thoroughly wetting a distemper background will remove old stains, but not always, though the treatment will do no harm, if it does no good, if the dust be carefully removed before the water is applied.

UNDER-EXPOSED NEGATIVE.—F. DUNSTER says: "I send you by this same post a roll, containing the 12×10 photograph of a landslip. The photo has been printed from my negative by one of the best photographic companies in the kingdom. Will you oblige by telling me wherein the fault of its extreme darkness lies? Can anything be done to the negative, or will it print better as a platinotype or bromide than as silver? I am not a photographer, but I bought last year a very fine series of negatives, all 12×10 and, with exception of this and interior of church, they have printed off beautifully."—In reply: Judging from the print sent, the negative sent is very much under-exposed. Possibly a better result could be obtained on gelatino-chloride or collodio-chloride.

TONING AND FIXING.—E. C. PEALL writes: "I have a question which I have been troubling myself very much about. I wish you to tell me if the prints toned and fixed in one solution have the same keeping quality as those done in the sulpho-cyan-toning and fixing bath in two solutions? I find it very easy to do my prints in the toning and fixing; would it be more permanent if I transfer them from the F. and T. into a solution of hypo?"—If the toning and fixing bath is used with judgments it is said to give stable results. But there is no question that toning and fixing in separate solutions gives much greater promise of permanence. It is for this reason that is generally preferred. There would be no harm done in using a fresh solution of hypo after the combined bath, even if it did no good. If two baths be used, why not tone in one—sulphocyanide and gold—and fix in the other?

*** Several answers to correspondents, Our Editorial Table, and many other communications are held over through extreme pressure on our space.

No. 1864. Vol. XLIII.—JANUARY 24, 1896.

Contents.

EX CATHEDRÂ.

The election of the Council and officers of the Royal Photographic Society, which takes place next month, is exciting great interest among the members of the Society. There are rumours of a contest for the Presidency, although what possible chance against Captain Abney most opponents could have it is difficult to discover. A self-elected caucus, however, has taken upon itself not only to run a candidate for the Chair, but also in the cause of "progress" is trying to exclude from the Council a few of the older members who have been re-elected for a good many years, but whose further presence on that body is supposed in some mysterious way to interfere with the progress of the Society—and photography.

* * *

The agitation for sending the old members of the Council to the right-about was certainly not organized with any appropriateness as regards time or opportunity, and, although the Special General Meeting at which the matter was discussed was, with the exception of two gentlemen, unanimously in favour of some inchoate plan for providing a free flow of new blood, it is possible that nothing further will be done in the matter for some considerable time to come. Some of the older members of the Council are said to make no secret of their determination not to stand for re-election; so that, if this should prove to be the case, there can be no great hurry to proceed with any ill-considered "new blood" scheme. Besides, there are many members of the Royal Photographic Society who are of opinion that in very recent years the enormous amount of time which the Society has passed in discussing questions of internal policy and detail has been, if not altogether unnecessary, at any rate largely in excess of the requirements of the case.

* * *

But why specially legislate for the introduction of "new blood" when, by the system of free election which the members still enjoy, the matter, as it always is and should be in self-governing corporations, rests entirely in the hands of the electorate, who have perfect freedom of choice—the ideal and only proper system of exercising the franchise? Time and nature are the surest agents of transfusion, as any one interested in this particular instance, may learn for himself by comparing the *personnel* of the present Council of the Royal Photographic Society with that, say, of 1890. Again, what changes and improvements have been effected in the Society during those years, all, be it noted, with the countenance and presence on the Council of this objectionable "anti-progressive" old blood! We venture to express the hope, as we expressed it last year in reference to an attempt to force gilt-edged men into the Council, that "members will vote solid for the old Council." A Society that has been governed as the Royal Photographic Society has during the last few years has nothing to complain of against its governors.

* * *

We are asked by Mr. W. I. Chadwick, of 2, St. Mary's-street, Manchester, to state that, at the request of honorary secretaries and members of photographic societies, he has arranged to attend their meetings and lecture on stereoscopy or the modern magic lantern. Of both subjects Mr. Chadwick has had many years' practical experience, and, in return for his services, he modestly asks that his out-of-pocket expenses only should be paid.

* * *

Messrs. Cadett & Neall, Ashtead, Surrey, forward us the latest price-list of their plates and other productions, with which some useful hints regarding development are given

They make the interesting statement that, since the introduction of their plates in 1892, "the sensitiveness of the gelatine dry plate has been increased six or seven times." An automatic exposure indicator, working with the dark slide, is also a recent introduction of Messrs. Cadett.

* * *

We are sorry to read in a French contemporary that M. Attout-Tailfer, whose name was associated with the introduction of orthochromatic plates as articles of commerce, died recently in Paris. The deceased gentleman, it was said, was a painter of great ability.

* * *

Professor Hubert Herkomer is a man of such marked energy and power that it would be running a serious risk to cast doubts on the probability of his being able to carry into execution all that he professed himself competent to do; nevertheless, we confess to entertaining a feeling of scepticism as to the literal feasibility of the *tour de force* in reproduction processes which, according to the *St. James's Gazette*, the Professor claims to have accomplished.

* * *

"If the reception," says our contemporary, "accorded on the Continent to Professor Herkomer's new invention is any criterion of what will happen when it is seen at the Fine Art Society's at the end of January, we may expect a cordial welcome to a process which plays so admirably into the hands of the artist. Professor Herkomer claims that he can convert a painted surface into a plate suitable for printing without the intervention of photography, or even of those preliminaries of biting, rocking, and other technicalities which have for so long deterred the painter from taking to etching or mezzotint engraving. He will now be able to be his own interpreter in black and white, with the full assurance that his direct touch and original idiosyncrasy will now, for the first time, reach the public. The Exhibition at the Fine Art Society's will consist of some forty plates, many of considerable importance, from Professor Herkomer's hand; and, as he has consented to have a demonstration of the whole process during the course of the Exhibition, those interested in this autographic art will be able, not only to see the result, but how it is arrived at." We await particulars of this process with much eagerness.

* * *

At Scarborough, during the months from May to October next, there is to be a Sports, Games, and Industrial Exhibition on a somewhat extensive scale. A class will be set aside for photography and the appliances connected therewith. Mr. Joseph Davis, Exhibition-buildings, Scarborough, is the General Manager, and all particulars may be obtained of him.

* * *

"Ignoramus," under which pseudonym an esteemed correspondent, who is a professional photographer, conceals his proper name, draws our attention to a newspaper paragraph which alludes to Mr. W. Ingles Rogers' recently recorded experiments in the development of images impressed in plates simply by the alleged persistent action of the eye. Our correspondent says: "I should like to hear what make of plate will give an image *without receiving any actinic rays*. It does not transpire at what distance the operator 'stared' at this wonderful plate, neither does it account for the fact that only an image of the coin, and *nothing else*, was developed. One is never too old to learn, so I await your reply with interest."

On the assumption that both Mr. Ingles Rogers' experiments with the retinal projections of coins and postage stamps were really performed as described, and that Professor Röntgen's remarkable results, due to the passage of the electric current through a vacuum tube and the opaque object to be reproduced, have been duplicated in this country (as is the case), the answer to our friend's question would appear to be that probably all commercial plates are sensitive to these "non-actinic" impressions. Doubtless, if Mr. Ingles Rogers sees "Ignoramus's" other questions, he will kindly answer them.

OPERATORS AND EMPLOYERS UNDER AGREEMENTS.

The lawsuit—Illingworth *versus* Draycott—tried at the recent Birmingham Assizes, before Mr. Justice Cave (see page 26, *ante*), is one of more than passing interest, as it illustrates several points in connexion with the photographic profession, such as we frequently have to deal with in the "Answers" column. Briefly, the facts of the case are these. The plaintiff, Mr. W. Illingworth, had been for some years in the employment of Mr. J. A. Draycott, as manager of a branch establishment of his. Then an agreement was entered into for the plaintiff to take the management of the Birmingham house, for a term of years, at a salary commencing at five, and rising to six, guineas a week. Under this agreement, the plaintiff undertook not to practise photography within a radius of eight miles of the defendant's establishments for five years after the expiration of the term. There was a clause, usual in such agreements, that the plaintiff could be dismissed with a month's notice for such things as gross mismanagement or neglect, insobriety, want of skill, misconduct, &c. After a few months the plaintiff was dismissed. It was on the ground of want of skill that he was dismissed.

The action was brought for damages for wrongful dismissal. Beyond the question of damages, there was another important point involved. If it was proved that the plaintiff was wrongfully dismissed, the learned Judge would hold that the agreement not to practise photography within the right eight mile for the stipulated time became void, and he could then practise the art wherever he might choose. This he can now do, as the jury found a verdict for the plaintiff with 200*l.* damages. That is but equity, as an agreement is binding on all the parties to it.

During the hearing of the case some interesting items in the internal working of studios came out. One was this: the plaintiff, it was stated, had taked 800 portraits, and out of that number there had been 153 resittings and twenty-five had second resittings, and the question arose as to whether that was an undue proportion. On this point the witnesses called for the defendant—and the learned Judge ruled, early in the case, that the onus of proof of incompetence rested with the defence—would not give any definite opinion. It was stated by one gentleman that some photographers almost courted resittings, while others would only give them with reluctance. With reference to some of the photographs called into question the Judge, in his summing up to the jury, said the defendant's order was, "Get their money and do something; and, if it is not liked, they can sit again." One of the witnesses, from London, said with regard to a group of four ladies, one of whom was going abroad, that in such a case he, to ensure a good result, would expose six plates—the plaintiff had only exposed three. This illustrates how so many plates are consumed by

some houses, and the cost at which some portraits are obtained. Six plates for one photograph would certainly be looked upon as an unnecessary expense by some employers. Those who are familiar with studio work will readily understand that out of eight hundred sitters, taken by any one, there would be some inartistic portraits, particularly with infants and young children, and the question before the Court was, under the circumstances, whether what was less than twenty per cent. was an excessively large number, and, as we have just said, none of the witnesses would say that it was. It is well known by portraitists that it often happens that a person will have several resittings, where they are given freely, and, after all, fall back on the first portrait taken.

An operator always labours under certain disadvantages in the studio, particularly if it has been worked previously by the proprietor; sitters, as a rule, prefer to be taken by the principal, although the operator may be the cleverer artist of the two. If a portrait does not please, it is no uncommon thing for complaint to be made, to the principal, of incompetence, or other fault, on the part of the operator. Out of the 800 sitters, thirty-eight letters of complaint had been received. On this point the Judge, in his summing up, said: "It was not within human possibility to please all, and, naturally enough, some complaints had been made. But were they excessive? No witnesses had said they were." Sitters will often have their own way with an operator, although he knows quite well the result will be unsatisfactory, while the principal would decline to let them have it, and with him they would acquiesce without demur.

Some parents will insist on having their infants photographed in a state of nudity, and it is frequently impossible for an artist to obtain an artistic pose, and at the same time a pleasing expression, and the results often turn out similar to some of the photographs referred to in the trial, and which might well be considered indecent by some. On the subject of photographs of nude children, Mr. Justice Cave said: "Although he should never desire such things, if parents come and say, 'I want them,' then he thought that the operator was only exhibiting that forbearance and effort to please expected from him if he endeavoured to grant their request." The learned Judge took a thoroughly practical view of the case throughout.

THE INTENSIFICATION OF NEGATIVES AFTER DRYING.

II.

Turning to collodion plates, we have, of course, entirely different conditions to meet, as the collodion itself, unlike gelatine, is impervious to water, though in most cases, at any rate of wet plates, the physical character of the film is such as to permit the water to penetrate it with considerable freedom. In many dry plates, more especially washed emulsion, however, the film is of so close and horny a nature after drying as to be absolutely impervious to aqueous solutions, and it is seldom that any satisfactory action can be obtained without proper preparation. Again, the difference between a bath plate or one on which the image has been produced by silver development must be taken into consideration as against those in which alkaline pyro or one of its congeners has been employed. In the one case the image consists of a more or less granular metallic deposit outside the film, while in the other it is embedded in the aforesaid horny layer of collodion. Wet-plate films consequently present comparatively little, if any, difficulty, while those on which chemical development has been used are always more or less troublesome to manipulate after once drying.

To prepare these films for subsequent treatment, they should be immersed, for a minute or two, in tolerably strong alcohol, and then laid in a dish of water until the spirit contained in the film has been replaced by water. When the latter is found to flow evenly over the surface, it should be poured away and a fresh lot added, which will cause a reappearance of the "greasiness," showing that all the alcohol has not yet been removed by diffusion; this must be allowed to remain until smoothness prevails, and the operation repeated, if necessary, until that end is attained. Not until the change of water ceases to produce "greasiness" should the tap or jug be resorted to, or unevenness in the after-process will be the result.

In very bad cases—where the collodion has become very horny and impervious—we have found considerable benefit from the addition of glycerine to the alcohol, in the proportion of one part of glycerine to seven of alcohol, which, in this case, may be of much lower "grade," "proof" spirit being quite strong enough. A few drops—a very few only can be safely used—of sulphuric ether may also be added, but this is an addition that must be resorted to with the greatest caution, and only in extreme cases. Wood naphtha or pyroxylic spirit also answers well, better indeed than ordinary alcohol, as it appears to open up the pores of the collodion more effectively. In using any of these latter solutions or mixtures of them, the same precautions must be observed as in the case of alcohol, namely, the water must be allowed to displace them as gradually as possible, and, this attended to, the final state of those films will differ little, if at all, from such as have not been dried.

As a matter of course, if the films have been varnished, the removal of the varnish is the first necessity; and, if this be properly effected, it follows that the film will be restored to a sufficiently porous condition, whatever its original character. The alcoholic varnish penetrates more or less into the "horniest" collodion film, consequently it acts directly in keeping it "open."

If any doubt exists as to whether a collodion negative will require subsequent treatment, it is advisable, before trying it, to flow it over with a weak aqueous solution of some substance soluble in water, that can afterwards be dissolved out. Very weak gum water, or albumen, or a five-grain solution of tannin, answers well; failing anything else at hand, a solution of loaf sugar may be used, but, owing to its hygroscopic nature, this should always be removed before finally varnishing the negative.

Pyro and Ammonia.—The cause of what might be termed the differential action of the various alkalies when added to solutions of pyro is still an undetermined problem. As a contribution to its solution there may be noted an extract from a paper, "Experiments in the formation of the so-called ammonium amalgam," communicated to the last meeting of the Chemical Society by Messrs. James Proud and W. H. Wood, F.I.C. They have found that sodium amalgam does not form the so-called ammonium amalgam when added to an aqueous solution of ammonia, and hence it can be used as a test for ammonium salts, even in the presence of free ammonia. They were able to show by these means that solutions of pyro and aqueous ammonia contained a compound in the nature of an ammonium salt. The amount of ammonia so taken up is, however, not stated.

Photography at the North Pole.—Our readers are, doubtless, familiar with the project of the Norwegian aeronaut, M. Andrée, who intends to try to reach the North Pole in a balloon. The project is only so far advanced as the final choosing of the material the balloon is to be composed of. This, however, is settled, and, at the same time, general arrangements have been planned. The Swedish physician who is to accompany the expedition will have charge of the photographic department, some idea of the expectations with regard to which may be formed when we state that it is said that 20,000 plates are to be taken. Films, we presume, will be used; but whether we are likely to see any views of the region so enveloped in mystery and speculation is very problematical.

Panoramic Projection.—A novelty in lantern projection has been devised by an American, Mr. Charr, and is fully described and illustrated in a recent number of *La Nature*, which acknowledges its indebtedness to the *Western Electrician* of Chicago. Briefly, the apparatus consists of a huge lantern installation, suspended from the ceiling like a chandelier. This contrivance holds the operator and eight lanterns, each lighted by an electric arc, and throwing a combined picture on a screen of cylindrical section, ninety metres in circumference and ten high. Extremely accurate registration is required, that in the junction of the views no awkward overlapping takes place. This is brought about by the accurate placing of the chandelier-like lanterns and lanternist stand. The pictures once arranged and planned for continuing in series, a further improvement is carried out by introducing kinetoscope pictures in motion, thrown upon the screen in the usual manner from a second lantern system. The apparatus is as ingenious as it must be costly, but we much doubt the commercial success of the scheme, especially at the present time, when, judging from provincial and other accounts, the public seem to be surfeited with lantern shows.

The Solar Eclipse.—The advertising columns of the scientific papers seem to be leading to lively incidents. The Orient Steam Navigation Company advertise the dispatch of two steamers Cook & Son personally conduct. Messrs. Gaze & Son send the *Norse King* to Vadsoe. *Nature* writes last week: "We notice with some astonishment, in a circular issued by Messrs. Gaze & Son, the statement that an official party of observers, arranged by a joint committee of the Royal Society and of the Astronomical Society, are proceeding to Norway, and will travel by the ss. *Norse King*. We can hardly think," continues *Nature*, "that this statement is authoritative, for scientific committeea are not in the habit of advertising their intention to patronise any particular line of steamers; and, further, astronomers usually require more than five days to adjust and set up their instruments, if any work of real use to science is to be done." Then comes a sneer at photography which much surprises us in the pages of this esteemed journal. "Of course, those photographers who merely wish to take snap-shots at the corona do not need to make any elaborate preparations, and, if the steamship they travel by carries them into harbour two or three days before August 9, they will have ample time to point their cameras properly."

Liquid Air.—We have already drawn attention to the fact that the production of liquid air is now a realised commercial project. Whether the consequent expected separation of a portion of the nitrogen from air at one stage of the process will be of any value as a practical supply of gas for lantern purposes remains to be seen. Meanwhile the processes of Dr. Dewar for the liquefaction and solidification of atmospheric air continue to excite great interest, and, incidentally we may state, acrimonious discussion, and at a recent meeting Dr. Dewar read a paper of absorbing interest on the subject.

He stated that when a litre of liquid air is placed in a globular silver vacuum vessel, and subjected to exhaustion, as much as half a litre of solid air can be obtained and maintained in this condition for half an hour. The solid state is comparable to a jelly, which, when examined in a magnetic field, has the liquid oxygen drawn out of it to the poles. The jelly is clear and transparent, but is milky if the carbonic acid be not removed. Of course this would be no commercial mode of obtaining oxygen and air, but the large apparatus he describes "can be arranged to deliver liquid air containing forty-nine per cent. of oxygen, which gives off gas containing twenty per cent. of oxygen, rising, after six hours, to 72·6 per cent. The percentage of oxygen can be increased by a slight change in the manner of working." By Linde's process, the plans of which are not yet published, liquid air containing seventy per cent. of oxygen in fifteen hours is obtained.

Dark-room Windows.—Now is the time to examine dark-room windows, especially those in which paper or "fabric" is used, in order to see that they are safe. Such materiala, we may say, invariably fade, or become lighter with time, and especially if subjected to damp or moisture. During the past month or two this condition has prevailed naturally, but at the same time the light has been so feeble that any fading of the window colour may have escaped detection—indeed, it is not by any means improbable that many of our readers may have been forced to intentionally "lighten their darkness" during the winter months, in order to be able to see at all. Now, however, the light is increasing in photographic value daily by leaps and bounds, and a window that may have been "safe" last week will, perhaps, be far from it next. This fact was forcibly impressed on us one bright day last week, in the case of a ruby glass window, over which, during the summer, we had stretched a sheet of yellow paper, which, however, has been removed during the winter. The bare glass alone has proved quite safe until an unusually bright and improving light, in conjunction with a fairly rapid plate, aroused us to the fact that it was becoming dangerous.

We may remark that it is a good plan, when paper or fabric is used, to employ a thin coloured glass also as a sort of protection to the paper. Coloured (yellow, or so-called "ruby") glass may be obtained cheaply enough that is quite unsuited for dark-room purposes, but a long price must be paid for such as is really fit to use; hence the general employment of such cheaper makeshifts as the paper and fabrics so widely used, which, however, suffer from want of permanence. But the cheap coloured glass, if not fit for use alone, suffices to protect the paper or fabric, and prevent its bleaching by the light; so a combination of the two affords a chesp, and at the same time efficient, substitute for the more expensive glass. For this purpose cheap pot-orange or yellow is dark enough to prevent the paper fading, and at the same time is light enough to admit of the use of a "safe" fabric.

SOLUBILITY OF SILVER IN HYPOSULPHITE OF SODA.*

From this experiment it seemed clear to us that access of air had something to do with the reduction of the density of the image, and in order to test this the following experiments were made:—

A glass tube, about eight inches long, was closed at one end and a strip of graduated paper introduced; the open end was then drawn out, and, when cold, a twenty-five per cent. solution of pure hypo introduced by means of a funnel. The tube was filled as full as possible and then sealed. It was not until a week had elapsed that the image turned somewhat yellow, and, though a reduction in density took place, it was not carried as far as in the case of the paper which was freely exposed, nor yet did it become as yellow, the gradations being plainly visible. The absence of air, therefore, considerably retarded the action of the hypo on the silver image.

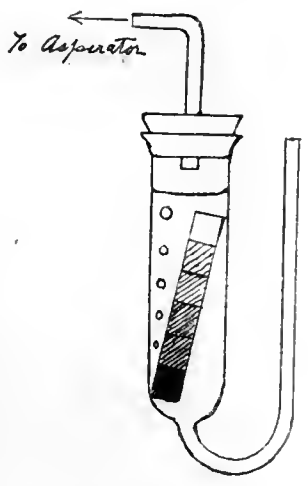
A piece of gelatino-bromide paper was then exposed to light, developed, fixed, and washed; it was then subdivided, one piece was placed in a glass tube, and the remainder in a beaker. A saturated solution of hypo was then prepared, and made faintly alkaline with a few drops of dilute ammonia; the water, previous to dissolving the hypo, was boiled so aa to expel dissolved air. The glass tube was then drawn out and by means of a small funnel filled with the hypo solution as soon

* Concluded from page 9.

as it was cold, the remainder being transferred to a beaker, in which were placed the other pieces of paper. The printed paper placed in the beaker was, at the end of four days, completely changed in colour, the greater portion of the density was gone, and, though the paper has now been in the same solution for twenty-five days, no further change has taken place. The discolouration of the paper commenced at the water line in the case of a piece which had a corner projecting above the solution of the hypo; the paper sealed in the tube so as to exclude air is, to all appearances, still of the same density and colour as when originally placed in the solution. In the case of the paper immersed in hypo in the beaker and exposed to air, the bulk of the silver seems to be in the hypo, as, on testing with ammonium sulphide, distinct evidence of the presence of silver was found. It is not possible to determine the quantity that is left in the paper and that which goes into solution, as the quantity of silver on a half-plate sheet of paper is too small for an accurate analysis. From this experiment we conclude that access of air is a necessary condition for the change of colour of the silver image and its solution in hypo-sulphite of soda.

The next point we endeavoured to clear up was whether, by bubbling air through hypo pure and simple, and then immersing a silver image in it, the action would go on at the same rate, or whether it was necessary for the silver to be present at the same time as the air was bubbled through.

For this purpose air was passed through a solution of hypo, nearly saturated, for twenty hours; then (1) a strip of a graduated lantern plate was placed in it, and the tube sealed: another portion of the original hypo was placed in a glass tube of the accompanying shape,



Method of bubbling air through hypo solution containing silver image.

together with (2) a strip of the same lantern plate, and air bubbled through for twenty hours; a third strip was sealed in a tube, air having been previously driven out of the water by boiling. The original lantern plate was exposed, so that there were six tints on it, each succeeding tint in the direction of increased opacity being exposed twice as long as the one preceding.

In the case of (1), at the end of nine days, tint No. 5 was as dense as tint No. 4 on the original plate, a slight change in colour accompanying the reduction in density, thus showing that the dissolved air had produced a certain effect in reducing the density and altering the colour.

(2)—In this case, at the end of four hours, tint No. 6 corresponded in density to tint No. 3, at the end of eight hours it equalled No. 1, and at the end of the period above stated, twenty hours, the density was completely gone, and only a yellow stain left in the gelatine, the different gradations being still visible on the plate when placed on a sheet of white paper.

(3)—This portion of the plate, though sealed in the same strength of hypo for the same time as in the previous experiments, viz., nine days, has not altered in the least; the only difference, in this case, being that the solution of hypo was, as nearly as possible, air free. These experiments point conclusively to the necessity of air being present, in order to bring about a rapid change in density and solution of the silver.

The above experiments show that a silver image may or may not be attacked when left in hypo of any strength, depending upon the circumstances at and during the time of immersion. In the experiments made by Mr. T. C. White, his films and silver were contained, respectively, in microscopic cells, and a test tube; in neither case had air free access, and it was in consequence of this that he noticed no change in the density of the film, and but little loss in the quantity of silver contained in the test tube.

In the experiments carried out by Mr. Sexton, though it is not stated, yet one may assume that the strips of paper were immersed in a horizontal dish containing hypo, to which air had free access; under these circumstances we should now expect a tolerably rapid change in colour and solution of the silver image.

With regard to Mr. Albert Levy's conclusion, we must say, from what we now know, that a photographic image cannot be appreciably reduced in the short time that it is immersed in hypo in order to ensure complete fixation. The experiment made with the mixture of metallic silver and silver bromide tends to prove this; also the experiment made with a developed plate, which was immersed for twenty minutes, being tested photometrically both before and after treatment, and which showed no difference in density. It is a fact well known to photographers that, if, after a plate has been developed and fixed, it is exposed to the air for a short time, instead of being washed, that the density becomes less; and that, if the image on removal from the hypo bath was black, after exposure it changes to a yellowish brown, which colour no after treatment with ordinary clearing solutions will remove. Here we have just those conditions which are best suited for attacking and dissolving the silver image. If the plate had been left in the hypo for the same length of time that it was exposed to the air after it had been fixed, no such reduction would have taken place. In the first case the hypo is exposed to the air in a thin stratum and in contact with the silver, and thus the air is able to act with much greater rapidity than when it has to penetrate a thick layer of hypo solution.

In examining the silver deposits on the gelatino-bromide plates which had been acted on by air and hypo, we were struck by the deep yellowish brown colour of the remaining silver, which was very different to its original black colour, and it appeared probable that as the hypo required the aid of air to effect the solution of the silver, this yellowish deposit was not metallic silver, but either a mixture of silver and silver sulphide or an oxysulphur compound: and, in order to investigate this point, we prepared some pure metallic silver and subjected this to the action of the hypo and air. Pure silver nitrate was taken, precipitated by means of ferrous sulphate, and the reduced silver boiled half a dozen times with dilute sulphuric acid, then with distilled water, and then treated with moderately strong ammonia to dissolve any soluble silver compounds, and finally washed six or seven times with distilled water, dried at 100° C., and placed in a stoppered bottle.

A portion of this was placed in the apparatus already described (fig. 2) and subjected to the action of hyposulphite of soda and air. At the end of two hours a slight change was visible in the colour of the metal, and at the end of fifty-seven hours it had changed to a dark reddish-brown. The action was then stopped, and the altered silver filtered off from the hyposulphite of soda solution, washed, and dried. The filtrate and washings were then treated with sulphide of ammonium in order to estimate the amount of silver that had gone into solution. This was found to amount to ·0420 grammes of silver. The reddish-brown body, which was found to weigh 1·7895 grammes, was then dissolved in dilute nitric acid and the silver precipitated with hydrochloric acid, filtered off, washed, and dried. On weighing this it was found to equal 1·7527 grammes of silver. The filtrate from the silver chloride was then taken down to dryness, with the addition of a little sodium carbonate on a water bath, hydrochloric acid added, and again taken down to dryness in order to get rid of the nitric acid. It was then taken up with water acidulated with hydrochloric acid, and, after being heated to the boiling point, precipitated with barium chloride, and the barium sulphate formed estimated in the usual way. This was found on

weighing to be equal to ·003 grammes of sulphur. Calculating from these figures the composition of the original compound, we get—

Silver	99·58	per cent.
Sulphur	·17	,,
Oxygen (by difference)	·25	,,
	100·00	

The amount of silver in solution was equal to 2·33 per cent. of the original silver taken.

The fact that silver is soluble in hypo in the presence of air has not been, we believe, observed previously, and we have made a few experiments in order to ascertain, if possible, the reason.

It is well known that, if a silver salt be dissolved, even in a large excess of hypo, it will after a time deposit silver sulphide in the form of a deep black precipitate, and it seemed probable that, if we heated together metallic silver with pure hyposulphite of soda, we should obtain silver sulphide and sodium sulphite. This was carried out by sealing in a glass tube some pure metallic silver and pure hypo, and heating the whole in a water bath to 100° C. When the tube was opened after boiling for five hours, the silver was quite black, and, on testing, was found to have become partly converted into silver sulphide, and the solution, which was kindly examined for us by W. P. Bloxam, B.Sc., by the method he recently published in the *Chemical News* for the detection of sulphides, polysulphides, sulphites, thiosulphates, and sulphates in the presence of each other, was found to contain sodium sulphite. On testing the solution for silver, only the merest trace was detected.

What happens in a solution of hypo through which air is bubbled in the presence of metallic silver is that the metal attracts sulphur from the sodium hyposulphite and forms silver sulphide, and the presence of dissolved air oxidises the silver sulphide to silver sulphate, which goes into solution in the excess of hypo.

We offer this as a possible explanation, subject to the correction of further experiments which we are now proceeding with, and we hope at some future date to communicate the results in a second paper.

F. B. Grundy.

THE SWELLING OF PHOTOGRAPHIC GELATINES.

It is known that a piece of gelatine soaked in water will take up a certain quantity and swell, says R. Ed. Liesegang, in the *Photographisches Archiv*. The so-called "hard" gelatines absorb less proportionately, and the "soft" more. Alum and other tanning substances bring gelatines into the harder condition.

These substances are therefore used to give photographic films sufficient capacity for resistance. The following also happens, to a certain extent. Let, for example, a commercial dry plate be soaked in water, it will take up much less than will a piece of pure gelatine of the same size, in the same time. More especially is this observable if we wish to remove the films from spoilt plates.

If, however, the same dry plate had been first developed and fixed, the swelling in the washing water would have been much greater. The susceptibility to mechanical pressure is increased. The film eventually becomes detached at the edges, &c. This can be referred partly to the influence of the developer, which, if strongly alkaline, has a softening effect. But the greater swelling capacity is also present, if development be effected with amidol or ferrous oxalate, which contain no alkali. Moreover, the swelling does not generally appear in development, but ultimately in the washing after fixing. This points to the fact, that the swelling of the film may be caused by other means than the softening compounds of the developer. Whilst the plate remains in the fixing bath, the effect does not appear. Usually the relief first becomes visible in pyro-developed negatives after they have been fixed and washed.

My researches respecting the formation of blisters on dry plates (vid *Photographisches Archiv*, 1895, p. 321) led me to make an experiment, which elucidates these peculiar phenomena of swelling.

Soak one corner of a bromide plate in a twenty per cent. solution of hyposulphite of soda, and another corner of the same for an equal time in pure water, and it will be observed that both parts have swollen equally. Now soak the entire plate in pure water, and the whole surface will become equally swollen, excepting the corner that has been treated with hyposulphite of soda, which is in much greater relief. The greater absorption of water at this spot is, moreover, very noticeable if, after thorough removal of the salt by washing, the plate is dried. The corner remains damp twice as long as the rest of the plate.

This peculiarity is not confined exclusively to hyposulphite of soda. If a portion of the plate is first treated with chloride of sodium or bromide of potassium, those parts swell more, similarly. Even treated with a powerful tanning substance—chrome alum—the parts appeared first in greater relief than where they had been simply washed; but, after prolonged action, the tanning effect asserted itself, and those parts again contracted.

Salts in solution therefore play an important part in the greater swelling of gelatine. But how? A direct softening does not occur. The modern physicist will fly to the theory of osmose, and explain that salts diffuse themselves through the film of gelatine, and pass into the water more slowly than the pure water penetrates the film. I prefer, myself, another explanation, which I should also like to apply to many other so-called osmotic processes.

It is not only the difference in rapidity of diffusion which brings about the pronounced swelling. The attraction of the surrounding water, by the concentrated solution of the salt in the gelatine, has much more effect. As this solution does not diffuse itself outwards with sufficient rapidity, the gelatine must yield. *The salt consequently presses the water into it.* If the gelatine cannot yield because it has been too strongly tanned, blisters arise, as described by me a short time ago.

The following facts are thus explained:—

(*a*) Why a finished negative, which has been once dried, seems to be much harder than one which has just been finished. It no longer contains any salts that could make the film swell more.

(*b*) Why printing-out gelatine papers cannot be hardened as much as development papers.

(*c*) The occurrence of blisters.

The following may also be inferred:—

(*a*) That the gelatine film swells less if weaker fixing solutions are used, or if salts in weak solution are used between fixing and washing.

(*b*) That plates or papers may be freed from hyposulphite of soda rather more quickly by a succession of baths—for instance, by introducing a salt in weak solution, or by using a more dilute fixing bath. The gelatine will then swell less, and consequently retain less of the solution.

(*c*) A few hints for the collotype process, to which I may refer more closely on a future occasion.

(*d*) Besides the interest this may have for photographers, there are the inferences physicists and biologists may draw therefrom in their departments.

ON THE PRINTING OF SINGLE FIGURES IN GROUP NEGATIVES.

I.

Of the many and varied commissions a professional photographer finds himself called upon to execute, perhaps there is none which he undertakes with more reluctance than that of abstracting some particular figure which is contained in a group negative, and which it is desired should be so enlarged as to form a cabinet picture by itself.

An operation of this kind will frequently be found to entail a good deal of careful manipulation, and at the same time take up a good deal of time in accomplishing, when the work necessitates the removal of the original background and the substitution of another and more suitable one for the same.

No doubt, in the majority of cases where groups are being dealt with, it will be found that, in nine cases out of ten, such have been photographed in the open air, and, as a consequence of this, very many of the sitters will be found posed with their hats or bonnets on: others, again, will be found who invariably prefer to remove such, even when being photographed in outside situations. In cases where the figures are found wearing their hats or bonnets, it may

frequently happen that advantage may be taken of the existing background, in which case the operation is performed with much less trouble than in cases where such has to be got rid of and another substituted.

The nature and suitability of the background is undoubtedly the main factor that has to be considered when undertaking work of this kind.

In instances where any figure is so posed that a reasonable amount of space is found to encircle the head and shoulders, and where the next figure in the group does not overlap in such a manner as to obstruct the head of the figure it is desired to operate, upon either in front or behind, the entire operation is easily and rapidly performed by treating that portion of the negative alone which contains the head and shoulders as an ordinary operation of enlarging would be executed on a single head picture. In the one case, however, recourse must be had to some method of blocking out or vignetting off all the surrounding figures, in such a manner that they will be entirely invisible in the resulting photograph. Much will at all times depend upon the space that intervenes between the figures in the original negatives in determining as to whether the operation should be conducted by vignetting or blocking off: the latter is undoubtedly the most easy of accomplishments, although any one who has never had such a job to perform would, no doubt, hardly consider this to be the case.

A very common example of this kind is where, say, a half-inch head, with hat and a fair amount of bust, is free to be worked upon without any objectionable background. In order to enlarge such to a reasonable extent, so as to form a pleasing cabinet picture, the simplest method to follow is to surround the head and shoulders with a small oval mask of a suitable size and shape, and then, by blocking out by means of black paper on the glass side of the negative all the rest of the original, the operation is very easily accomplished by simply enlarging the now masked-out head directly on to any desired sensitive support. To those who may say, "Oh, yes; but how are you to get an oval mask of such small and exactly suitable dimensions to enable this work being performed so easily?" To such, no doubt, this method would seem to offer insuperable difficulties; but, in reality, such is easily provided once any one knows how to set about making it. To cut a small oval mask is not a feat that requires much pains or trouble; but there is another way of making them with the greatest ease, and it is a method quite within the scope of any photographer. Here is how to set about it. Every professional will have beside him a few cut out—whole-plate or other sizes of masks—if not, for a trifling sum he can acquire such from any dealer. Along with these cut-out masks the makers supply the cuts-out or centre discs which correspond to the shape and size of the masks. Let any one desirous of making, say, a small oval-shape mask, of about one inch in size or any other dimensions, take one of these cuts-out, and, by attaching it to a white card or sheet of opal, let him proceed to photograph this black shape to the exact size he wants his little oval to assume. There is certainly no great trouble in doing a job of this kind. In photographing this, sufficient density may be gained by development and after intensification of the negative so produced, provided the operator knows how to make black-and-white negatives; if not, the sooner he learns the better. If it be found that sufficient contrast has not been gained, *i.e.*, the centre does not appear as absolute clear glass and the blacks so dense as a candle flame is hardly perceptible through the opacity at a distance of eighteen inches from the flame, then the operation has not been skilfully performed, and, as I have said, the operator should learn how to do work of this kind, for in these days of line and half-tone process blocks, a thorough knowledge of black-and white working on a photographer's part is an absolute essential to success.

Should it, however, be found that sufficient density has not been gained, then there is no great difficulty in tracing the form of the oval with a good sable or camel's-hair pencil charged with a good black pigment. This will at all times give the desired opacity. Having provided the mask, which is nothing more nor less than a negative image of the block cut out and the white card, let this be placed in position over the head and bust of the figure it is desired to abstract. This is best done on the glass side, by simply attaching it to the desired spot by means of strips of gum paper. One of these cuts-out is a very handy key to keep in stock in the manner I have indicated, and for this reason, that any size of oval, either large or small, is easily produced, by photographing it in the manner I have described.

Should it be desired to print the head by means of one or other of the modern excellent platino-bromide papers which are now so deservedly popular, then a dozen or so copies are easily pulled off by means of placing the negative in the copying box, and making a small enlargement by daylight after any of the approved methods. When the operation is gone about in this manner, very excellent results are rapidly produced. Should it, on the other hand, be desired to print the picture on a less suitable medium, such as albumenised or other printing-out papers, then it becomes a more roundabout operation, and necessitates the making of an enlarged duplicate negative by any of the most convenient methods. These platino-bromide prints, however, are very easily worked up in black-and-white by those having a little experience at this branch of work, and with a reasonable amount of care in exposing and development exactly similar proofs are easily obtained.

It is not in every case, however, that an oval shape will be found to suit the requirements of the particular head being dealt with. Sometimes, owing to the nature of the surroundings in the original negative, other shapes, such as rounds or squares, will be found more suitable to adopt, for the purpose of stopping out those portions not desired. The cutting of a very small round mask is also easily performed, once an operator knows how to do it; but there is also in this case a far simpler way of providing a round aperture to encircle the head, and it is so ridiculously easy to do, that no doubt many will smile when they read the remarks which I now pen.

Suppose any one wants a small round mask of, say, half, three-quarters, or one inch in size: all he has to do is to take for this temporary purpose one of his stops. This is easily gummed on the negative in the same manner as I have described. Necessity is the mother of invention, and I hit on this dodge one day when I needed a three-quarter inch round badly. I can assure the readers of The British Journal of Photography that any of their stops will be found useful for this purpose; in fact, they are the very things required. Squares or oblongs are quite as easily provided, and sometimes such will be found more suitable than either ovals or rounds; all will depend on the nature of the backgrounds and the surroundings of the figure.

In cases where it is desired to furnish a vignetted head, the operation entails considerably more trouble, particulars of which I hope to give in my next article.

T. N. Armstrong.

CLOUD PHOTOGRAPHY.*

[Nature.]

The blue colour of the sky has as much action on an ordinary sensitive plate as the white colour of light clouds (cirrus and cirro-cumulus); it is therefore necessary to diminish the action of the blue background of the sky. For this purpose a yellow screen is placed so as to intercept the rays; the light coming from the sky contains very few yellow and green rays, and is thus extinguished to a great extent; but, on the other hand, the great proportion of yellow and green rays which exists in the white light of the clouds passes the screen and makes an impression on the plate, if it has been made more sensitive to the action of yellow and green rays than the ordinary plates.

There are, therefore, three points to be considered: (1) the coloured screens; (2) the sensitive plate; (3) the method of development of the images.

(1) The Coloured Screens.

Coloured screens formed of films of gelatine or collodion must be rejected, because their tint changes very quickly in the light, and they easily lose their transparency. Either yellow glass must be used, or cells containing a suitable liquid.

Yellow glasses make the most convenient screens of all; but the difficulty is to find suitable glasses which are always the same, and of sufficiently graduated shade. Some are excellent, others not worth anything. Before recommending the use of coloured glasses exclusively, some experiments ought to be made with the help of a glass-maker, in order to ascertain what ought to be the exact composition of the glass so that it may be reproduced with the exact tone at any time. It is unnecessary to add that the glass must be homogeneous and polished with quite parallel surfaces; only glass ought to be used which is coloured in mass, and not white covered with a superficial layer of enamel.

The surest method, in the case of not being able to get glass of which the composition is known, would be to use liquid screens, as I do. They are made with two parallel square glasses cemented together on three sides by square glass rods also with parallel sides, and with a thickness of six or seven millimetres, and length of side seven to eight centimetres, one side remaining open. If one does not wish to go to the trouble of

* Translated from *Cosmos*, November 23, 1895.

making them, these cells can be obtained from instrument-makers. Needless to say that, before cementing, the glasses must be carefully cleaned with a solution of carbonate of soda, then with water, and lastly by being well rubbed with a piece of cotton-wool dipped in alcohol; with these precautions, no air is to be feared along the sides of the cells. Before introducing the liquid, care must be taken to dip the open end of the cell in a bath of resin (a mixture of yellow wax and resin of equal parts). For ultimately closing the cell, it suffices to fasten on the edges, thus covered with resin, a little plate of glass cut to a suitable size, and which must be heated on a plate of copper to prevent its breaking. If found desirable, the aperture may be still more securely closed with sealing-wax. Thus cells are obtained hermetically sealed, which can be used at every inclination without the liquid spilling and without air getting along the joints.

The easiest way of fixing these cells in position is to pierce a circular hole in the centre of a flat piece of cork, the size of the sunshade of the lens of the camera. The plate is fitted into the sunshade and held by indiarubber. The screen is thus in front of the lens, and it can be easily replaced by others more or less dark.

For the liquid I have had to reject all solutions of organic colours, such as aurantia, primuline, chrysoidine, for they alter in the light. The simplest one is to use the bichromate of potash. A saturated solution is prepared at ordinary temperature, to which is added, after straining, a few drops of hydrochloric acid. This saturated solution, introduced into one of the previously described cells, constitutes screen (1), which should be used when the clouds are very light, and the sky of a pale blue. A solution of half the strength forms screen (2), which may be used for well-lighted detached cirrus on a really blue sky; lastly, screen (3), consisting of one part of the saturated solution to three of water, should be reserved for very luminous clouds as cumulus and cumulo-nimbus.

It is certainly more convenient and more simple to use coloured glasses as screens; but, while there is a doubt as to finding suitable glass, we can always be certain when using bichromate cells of straightway obtaining excellent screens, always precisely the same. The ones I possess have been in use two years, and no precautions have been taken to preserve them.

(2) Sensitive Plates.

Special plates must be used for yellow light. The way of preparing these plates by means of ordinary plates is already well known; I did this at first. But I am certain that the necessity of preparing the plates is the principal obstacle which stops people taking photographs of clouds who are really desirous of doing so. However, prepared plates are to be had in the trade, and they serve the purpose admirably.

Among the types of plates called orthochromatic or isochromatic, two have given me excellent results: Lumière's orthochromatic plates, sensitive to yellow and green light, and Edwards's orthochromatic plates.

There is, therefore, no necessity to prepare plates, as they are to be had ready-made, and at least, in most cases, quite as good as those one could prepare personally. It has been said that the sensitiveness of these plates alters very soon, so much so that they are useless at the end of a few months. With regard to this, I can but quote the following fact. In February 1893, I received from the firm of Lumière three boxes of orthochromatic plates, of which the date of manufacture is unknown to me. These three boxes were simply placed in a cupboard of my bureau without any other precautions. The first box of twelve plates was used in the course of 1893, the second only opened at the beginning of 1894, and used between the months of March and November; lastly, the third box was opened only in November 1894, and the two first plates gave negatives which did not differ at all from those obtained from similar plates twenty months before.

Other similar boxes opened, then forgotten for some months in a cupboard, have always given me excellent results.

I intend to continue these studies; but it seems to me now established that, if the sensitiveness of these plates diminishes with time, this diminution is small enough to permit of the plates being used after more than eighteen months. Under these conditions nothing can be said against their use.

Focussing is done without any difficulty on a distant object—for instance, on a house in bright light. If the horizon is not far enough distant, an object can be taken comparatively near (at least twenty-five or thirty metres); then, in order that the position shall correspond with infinity, move the ground glass towards the lens a distance $\frac{f}{k-1}$, f being the focal distance of the lens, and k the number of times that the distance of the object which has been focussed contains the focal length of the lens. For instance, if an object twenty metres distant has been focussed with a lens of which the focal length is twenty-five centimetres, then we get $k = \frac{2000}{25} = 80$. In order that the clouds may be in focus, the ground glass must be brought a distance of $\frac{25}{79} = 0{\cdot}32$ cm., about three millimetres, nearer the lens. Of course, the focus must be got with the coloured screen, and the position thus found must be marked on the base of the camera, in order that the position of the frame may be known.

(3) Development.

No mode of development must be rejected *à priori*; even developers called *automatic*, which can be bought ready-prepared, and which have been very much run down, for they are by far the most convenient, and often give excellent results.

If the negative that we wish to develop contains only clouds of more or less the same intensity, the automatic developers may be used without any risk. I have used baths of hydroquinone, Lumière's developer (of para-amidophenol), &c. with success. It is advantageous to use baths which have already been used, and consequently containing a good proportion of bromide; a greater contrast is then obtained between the clouds and sky, and the development can be carried further without fear of fogging.

If, on the contrary, the negative consists of clouds of very unequal luminous intensity, as, for instance, delicate cirrus and strongly lighted cumulus, the negative would not turn out well with automatic developers containing much bromide; the image of the cumulus would appear, and be over-developed, before that of the cirrus had begun to show itself. In this case either a new bath must be used, very diluted, without bromide, and the development is then very slow, or else (which is preferable) use pyrogallic acid, in employing the method recommended by M. Londe. In this case the development must be commenced with a very small quantity of pyrogallic acid, a little bromide, and relatively enough carbonate of soda, in such a way as to make all the parts of the image appear at first, without much intensity; then the necessary intensity will be obtained, little by little, by the successive additions of pyrogallic acid. It is in this case only, where the intensity of the clouds is very different, that I think it advantageous to recommend progressive development instead of pyrogallic acid. In most ordinary cases, however, the automatic developers, which are more rapid, and more convenient to use, act very well.

In fact, it is always as well to continue the development till the image is sufficiently dense, without intensifying, which is almost always possible. Negatives ought only very exceptionally to be intensified; to my mind, the intensification is always bad, it spoils the detail; a renewed or feeble negative is never worth as much as one that was made sufficiently dense in the first instance.

If I have gone into all these details, it is only to show that photography of clouds is a very easy operation, and within the reach of all amateurs. And let me just add that, with the darkest screen (saturated bichromate) and Prazmowski's lens, with a focus of 160 millimetres, and diaphragm of $\frac{1}{30}$, I obtain negatives with a maximum exposure of six seconds for cirrus, with an ordinary amount of light with a Zeiss object-glass, a diaphragm of $\frac{1}{15}$ and very bright cirrus, having an exposure of $\frac{1}{30}$ of a second, has sometimes been more than sufficient, even too much.

It would be very interesting if amateurs in photography, so numerous at the present time, would try to photograph clouds which strike them as having interesting shapes, noting with care the hour when they were taken, and also the direction in which the clouds appeared.

LANTERN SLIDES AND THEIR MAKING.

At the meeting of the Brixton and Clapham Camera Club, held at Brixton Hall on Tuesday, January 14, the President, Mr. J. W. Coade, in the chair, a large number of the members and friends were in attendance, the fixture being *Lantern Slides and their Making*, by Mr. E. Dookree. The lecturer, in his opening remarks, pointed out the fallacy of attempting to proffer practical information to those present by the development of a lantern slide, as only those near the object itself would be able to gain any knowledge by his manipulations; he therefore proposed to touch as concisely as possible on all the technicalities of making a slide, from the negative to be chosen to the binding of the finished slide, concluding his remarks by projecting on the screen magnificent slides by some of the best-known workers of the day. Continuing, he touched upon the two methods of making a slide, viz., reduction and contact, of which he always preferred the former, averring there was always an indescribable

something about a picture obtained by reduction, not obtained by contact printing. The camera he used was one of Griffiths' fixed focus, fitted with a Taylor, Taylor, & Hobson lens, altering the aperture of the same as circumstances required. The class of negative which gave the finest result in his hands was that of a *soft* but vigorous class, in fact that which would yield a good platinum print, was first class for slides and developed to that end. The lecturer then handed some six half-plate negatives, bound up with ground glass, round for the inspection of those present, touched briefly upon the processes—albumen, collodio-bromide, and chloride, carbon, and gelatino-bromide and chloride, saying he had found it possible to obtain all he required on a gelatino-bromide (slow) plate—giving the preference to Paget's, by reduction. Proceeding to give the formula of the Paget developer and times of exposure according to the light available, he said, after a little experience the tone required by the manipulator was easily obtained, judicious use of bromide of ammonium being a most important point, tones ranging from velvet blacks to purple and red varying according to the exposure and restrained development. The advantage of a slight veiling of the slide was shown, adding a softness to the resulting picture when projected on the screen. Should intensification be deemed necessary, he invariably used that of Mr. Boothroyd's formula, and published by Messrs. Cadett & Neal, in the November 1894 number of their *Dry Plates*. It is possible by this intensifier to build up a ghost of an image into a very fine slide. It is as follows:—

A.

Pyro	6 grains.
Citric acid	15 ,,
Water	1 ounce.

B.

Silver nitrate	30 grains.
Water	1 ounce.

Distilled water should be used, or milkiness of solution will result.

For use, take sufficient of A to cover plate, and add to it two or three drops of B. But the plates must be absolutely freed from all hypo by washing, or stains will result. Before binding up a slide, varnishing is recommended, that composed of amber dissolved in chloroform being the best as it dries immediately, and also forms a very fine tooth should retouching be necessary. As regards masking, he strongly pointed out that as much care is required as would be bestowed on the shaping of a print, square corners, except in portrait, photo-micrographic, or flower studies being essential for a good appearance on the screen. He always made his own masks out of the thin, opaque, black paper in which the lantern plates were wrapped. By making them himself, he obtained "real square corners." Spotting, binding, and titling being unnecessary to go into, Mr. Dockree concluded by mentioning the following points. It was as possible to obtain an artistic result by photography in a lantern slide as on paper, notwithstanding what had been said to the contrary by those who excelled in the one branch and not in the other, as the audience would see by the specimens projected on the screen later on. Let the worker's watchwords be "detail first, density afterwards," which, combined with good technique and an "artistic composition" in the negative, the result would be pleasing to the most critical. After an animated discussion, in which the demonstrator explained points which he had not touched upon, such as brush development and the great advantages obtained by a judicious use of ferridcyanide of potassium, printing in clouds, either on cover glass or subject glass, &c., some magnificent specimens of slide work by such well-known workers as Messrs. J. Hankins, J. H. Gear, Edgar Lee, and E. R. Ashton, were projected on to the screen, and met with the applause they so richly deserved.

THE BIRMINGHAM AND MIDLAND INSTITUTE
CONVERSAZIONE.

This annual *conversazione* is probably one of the most successful held out of London, and is attended by very large numbers of the inhabitants of Birmingham and district, and, besides the attractions held out by numerous scientific exhibits, there is dancing every night, and an opera by some of the principal amateurs of Birmingham, who this year chose the *Pirates of Penzance*.

The photographic exhibits included a very fine series of prints of Warwickshire windmills by Messrs. E. C. Middleton and Harold Baker, which have been made in connexion with the photographic survey of Warwickshire. The diversity of shape of the windmills was extraordinary, and, although they could hardly be said to be artistic, they attracted a good deal of attention and the interest of archæological students.

Mr. Charles Pumphrey showed some stereoscopic slides of compound curved lines, drawn by machines, which were not only pretty, but exceedingly delusive, the lines looking like so many solid wires interwoven in the most intricate patterns.

The tintometer, which was shown by Mr. E. J. Wall, is used for analysing colours of all kinds, and is, we learn, to be applied to the reading of the speed of plates and the printing powers of negatives, some work already having been done on these lines.

The incandescent gaslight has before now been applied to artificial light portraiture, and Mr. J. W. Beaufort, of Colmore-row Birmingham, had one of Best's patent Beaufort lights fitted up on a stand in one of the rooms. This light consists of a cluster of nine incandescent gas lamps, without chimneys, arranged under a parabolic metal reflector, lined inside with white asbestos, the whole being swung on a weighted and pivoted arm, so as to be adjustable in every direction. The consumption of gas is by no means heavy, and complete control of the lighting is obtainable, the exposure for an ordinary bust portrait being about two or three seconds.

Dr. Hall Edwards' exhibit, whilst including some stereo photo-micrographs by Mr. Iles, and some lantern slides chemically coloured by glaucotone, mounted by Mr. Iles, which certainly produces the most wonderful tones on commercial lantern plates, ranging from pale pink through every shade of colour to deep black brown, consisted mainly of some marvellous figures, produced in the form of lantern slides which illustrated the forces of cohesion, adhesion, and diffusion. Every evening too, were projected on a screen, by means of an electric lantern (specially lent by Messrs. W. Watson & Son, of Holborn) the formation of coloured figures by means of various dye solutions.

The Aerograph or Fountain air brush was also shown by Mr. Chas. Burdick, and the results, produced by means of this instrument, in water colours were much admired.

The general exhibits included the application of the Mulver portable batteries to electric lighting and motor carriages. Microscopes with various interesting subjects, under ordinary and polarised light, also drew large numbers, and the sound generators invented by Mr. Gould, of Nottingham, drove many out of the room in which they were exhibited, by the terrible volume of sound they generated. They consist of steel bars of various thicknesses and length, and which were excited by vibrating rubbers on flexible steel rods, producing notes of remarkable purity and volume, and in which the sound waves were distinctly heard and felt by a sensitive ear. One of the most generally attractive exhibits was the living ants shown by Mr. Henry Burns, who, at intervals, gave interesting details of their mode of life, &c., and who excited considerable surprise by making an ant hold a sixpence and rather heavy pencil case with its mandibles.

ALLEGED SHAM PHOTOGRAPHERS.

On Tuesday, January 14, at the Bristol Police-court, Messrs. Alfred Robinson and W. H. Budgett dealt with an adjourned case in which John Saunders, of respectable appearance, and his son, John Saunders, were charged with obtaining various sums of money by false pretences, there being seven charges in all.

Mr. H. H. Gore, who prosecuted, stated that since the end of September or early part of October last the prisoners had been carrying on business as photographers, of 2, Melville-terrace, North-street, Bedminster. They took a number of photographs of houses in different parts of Bristol, including, he believed, that of Mr. Budgett. (Laughter.) Early in November they began a course of systematic frauds. In one case the elder prisoner called at 25, Great George-street, the residence of Archdeacon Robeson, and, having asked permission to photograph the house, he suggested to the servants that they should appear in the view. This was done, and the prisoner, after making a pretence of taking the photograph, induced the servants to pay him 10s. for copies which he promised them. Afterwards the prisoner visited the Deaf and Dumb Institution, and, after taking a photograph of that building, with the children in front, he obtained 6s. from the Superintendent by promising copies. In the same way he obtained small sums of money at Stanhope House Industrial School, at Carlton Industrial School, and at Park-row Industrial School. But the cruellest case of all was at St. Raphael's Almshouse, the inmates of which had no money except trifles given them by visitors. Going there, the elder prisoner induced the poor old folk to borrow 1s. each to pay for copies of a photograph which he promised and pretended to take. In most cases the loss had fallen upon people who could ill afford to be defrauded. Although the prisoner, when making a call, pretended to make an entry of the order, the pages of the book in which he appeared to do so were covered more or less with scribble marks indicating nothing at all, and obviously a mere pretence of writing. Mr. Gore concluded by saying that, if he satisfied the Bench that there was not a *bonâ fide* entry with regard to any one of the seven cases on the charge sheet, he should submit it was evidence that he did not mean to carry the orders into effect.

The evidence given by Elizabeth Mutlow, in the Archdeacon's service, was read over. In reply to further questions, she stated that on Sunday, January 5, the day on which the elder prisoner was arrested, his son came to 25, Great George-street, and wanted to take a photograph, saying the one taken in November had been lost. She paid the elder prisoner 10s. in November. On January 6 she told the younger prisoner he must come next day, and he took a photograph, in which none of the servants appeared as on the former occasion.

Louisa Richards, also in service at 25, Great George-street, gave corroborative evidence.

Catherine Macfarlane, matron at Carlton House School, said the prisoner called there on November 21, and said he had come to take a photograph of the house for an architect's society in London. It was arranged, on the suggestion of the prisoner, that the children should sit

in front, and the prisoner made a pretence of taking a photograph. Afterwards she gave him 1*s.* 6*d.* for a copy, which he promised, but she would not advance 10*s.* or 10*s.* 6*d.*, which he wanted to pay for copies for several of the girls. She never received the photograph.

Annie Williams, laundry mistress at Carlton House School, said she also paid 1*s.* 6*d.* for a photograph, which she never received. The prisoner pretended to write the order in the book produced.

Similar evidence was given by Isabel White, assistant teacher at Carlton House.

William Barnes Smith, master of the Deaf and Dumb Institution, deposed that on November 9 the elder prisoner asked for permission to take a photograph of the building, and it was arranged that the children should be included. Witness thought the man took the photograph in a slipshod way, and suggested that he should take another, but the prisoner replied that it was a very good one. He paid 6*s.* for copies, but never received them. About a week after the prisoner's visit witness received a postcard from him, saying the photograph, which should have been completed by that time, was not satisfactory. Witness asked for his money back, but did not get it.

The elder prisoner said it was true that the negative was not satisfactory. It was taken with real apparatus.

Edwin Chaffey, headmaster of Park-row Industrial School, said the prisoner visited that place as he had called at others, and obtained 4*s.* 3*d.* The prisoner pretended to write something in his book.

Fanny Chandler, matron of Stanhope House School, said she paid the prisoner 10*s.*, and he appeared to enter the order. About a fortnight later the younger prisoner called, and, in connexion with a complaint by her with reference to his father, he stated that the weather had been unfavourable for the printing.

Thomas Chamberlain, an inmate of St. Raphael's Almshouse, said he was induced to borrow 1*s.* to pay to the prisoner. He called at the prisoner's house two or three times, but could not get the photographs

Mary Cogswell, of 25, Somerset street, Kingsdown, said she paid 7*s.* for photographs of the outside and of the inside of her premises.

The prisoner stated that he had a negative of the St. Raphael Almshouse, and it was produced. He added that a photographer could not be held responsible for bad negatives.

Detective Perry said it was the only negative in the case that was produced.

The case was adjourned, the prosecution intimating that other charges would be entered against both prisoners.

PROSECUTION UNDER THE PHARMACY ACT.

THE Pharmaceutical Society, of 67, Lower Mount-street, Dublin, were the complainants, and the defendants were Matthew Ballantine and James C. Carson, proprietors of the firm of, and trading as "J. Lizars," of 73, Victoria-street, Belfast. There were three summonses in the case, in the first of which the defendants were charged with having, on October 7, last, sold a poison—bichloride of mercury—to Andrew Downey, the said Andrew Downey being a person unknown to them, and not having been introduced by a person known to them, contrary to the provisions of the Sale of Poisons (Ireland) Act, 33 and 34 Vic., cap. 26, sec. 2. In the second summons the defendants were charged with keeping open shop for retailing and dispensing poisons, they not being properly qualified under the Pharmacy Act (Ireland), 1875. In a third summons, the defendants were charged with selling and retailing and dispensing a poison on the day named.

Mr. S. Millin, barrister-at-law (instructed by Messrs. Galway & Clark) appeared for the plaintiffs, and Mr. E. J. Shaw (of Dinnen & Shaw, solicitors) appeared for the defendants.

Mr. Millin, in stating the case, said that there were three summonses against the defendants—for keeping open shop for retailing poisons, for selling a certain poison, and also for dispensing poisons, they not being properly qualified to do so. The principal Act was the Act of 1875, but that had been followed by the Amendment Act of 1890. Sections 15 and 17 of the Amendment Act of 1890 really contained the exact words of section 30 of the principal Act of 1875. Then, in 1893, section 30 of the principal Act of 1875 was repealed in part, because it had been already enacted in sections 15 and 17 of the Amendment Act of 1890. He would ask that an addition should be made to the summonses embracing these two sections of the Amendment Act, as he preferred to rely upon them.

Mr. Shaw objected to any amendment of or addition to the summonses. The Society had had three months within which to issue proper summons. He would ask their Worships to refuse to amend, and instead to give him a dismiss.

Mr. Nagle said, as the defendants did not seem to be damnified in any way by it, there was no reason why the addition should not be made.

The Bench then made the addition asked by the complainants.

Andrew Downey deposed that on October 7 last he purchased an ounce of pyrogallic acid, an ounce of sal-ammoniac acid, and an ounce of bichloride of mercury in the defendants' shop from a young man. He gave the bichloride of mercury to Mr. Templeton for analysis.

By Mr. Shaw: He told the young man that he wanted the bichloride of mercury for the purpose of intensifying negatives. He signed his name on the usual book as provided under the Poisons Act. He had a camera at home, and knew a little about photography. He purchased some bromide paper. He was instructed by the Society to purchase these articles.

Samuel Templeton, analytical chemist, said the article submitted to him was a deadly poison, and sufficient to kill the legal fraternity in Belfast. (Laughter.)

Mr. Millin said neither of the defendants were entered on the register of druggists and chemists.

Mr. Shaw submitted that no case had been made out. The defendants employed a registered druggist, and all the chemicals and poisons used for photographic purposes were under the control of Mr. Hogg, who, it was admitted, was a registered druggist. The summons charged them with having sold these articles to a person unknown to them, but, as a matter of fact, they knew he was employed by the Society.

Mr. Nagle: Is it admitted that the assistant is registered?

Mr. Millin: Yes.

Mr. Nagle said he would like to know on what basis Mr. Millin was going with his case.

Mr. Millin said his contention was that, if a person was himself registered, he could employ another, but that a non-registered person could not employ one who was registered.

Mr. Nagle: You have really a case, but the question is, Has the summons been properly framed?

Mr. Millin said the summons was framed under Section 30 of the Act of 1875. The section had been partially repealed, but re-enacted in Sections 15 and 17 of the Amendment Act of 1890.

Mr. Nagle said it was clear that the charge was not framed according to Sections 15 and 17 of the Act 1890.

Mr. Hogg said he was the manager for the defendants. He detailed the facts regarding the sale of the articles to Downey. When he asked for the bichloride of mercury witness said he supposed he was going to intensify negatives, and he said he was. Witness said he would require to be cautious, and he said he had used it dozens of times. He had seen Downey before this date, and knew that he was a servant of the Pharmaceutical Society.

To the Court: He knew that he was a servant of the Society before he wrote his name on the book.

Mr. Nagle said: On the whole evidence, the magistrates considered that the man was not known to the defendants strictly within the meaning of the Act of Parliament. They considered it really only a technical offence. A little more care would have obviated the difficulty. Under the circumstances they would make a nominal penalty in the first summons of 10*s.*

Mr. Milne said, if they considered it necessary to ask to have a case stated, they could apply within the three days allowed.

Mr. Nagle: Certainly.

Mr. Shaw asked to have the other two summonses dismissed with costs.

Mr. Nagle said they would not give costs.

LANTERN SLIDES OF CATHODIC PHOTOGRAPHS.

Last week we referred to the fact that, following on the lines laid down by Professor Röntgen, Mr. A. A. C. Swinton had succeeded in obtaining photographs by the agency of radiations from a Crookes tube through an ordinarily opaque body. These photographs were shown at the Camera Club meeting of Thursday, January 16, and excited much attention. We have since had an opportunity of examining the negatives. In the case of one—a negative of Mr. Swinton's hand—the bone structure is shown with remarkable effect. Other subjects are not less surprising as illustrating this new adaptation of photography.

Messrs. Newton & Co., of Fleet-street, are supplying lantern slides from Mr. Swinton's negatives, and, doubtless, many of our readers will be glad to avail themselves of the opportunity of studying these interesting subjects.

Our Editorial Table.

The Photographer's Miniature Annual.

By T. Bolas, F.I.C. London: Carter & Co., 5, Furnival-street, E.C.

This is a volume measuring 2½ inches by 2 inches, which claims to supply the want of "a book which, while containing varied information, may be of such a size as to be carried in the pocket for handy reference at any time." If we are not misinformed, our own Almanac, in the early stages of its career, was the object of a like aim on the part of its compilers. The *Miniature Annual* contains 58 pp. of ably selected and condensed information, the few formulæ, tables, the calendar, and other information printed being such as one would look for and be glad to find in the book.

The London Photographic Supply Company's Price-list.

The Company, writing from 63, Great Dover-street, Borough, inform us that they send this Catalogue free to the trade. It is a book of about 260 pages, which recapitulates and illustrates the requirements, in great variety, of professional and amateur photographers.

Modern Magic Lanterns and their Management.

By R. Child Bayley. London: L. Upcott Gill, 170, Strand, W.C.

Mr. Child Bayley's little book is a complete and not too diffuse introductory guide to optical lantern work. As regards illuminants, oil and limelight are fully treated of, and the author, while rightly thinking it not worth while to say more of saturators than is demanded by the slight vogue they have obtained in practice, wisely includes chapters on home-made oxygen and the electric light—two subjects that are likely to interest the lanternist for a good while to come. The final chapters of the book are devoted to experimental work with the lantern, projection spectroscopy, polariscopy, and microscopy also coming in for descriptive treatment. This section, appearing in a work issued at the small price of 1s., will therefore be doubly welcome. The book throughout has been carefully and judgmatically compiled, and is calculated to be of great practical use to lanternists—beginners, or otherwise.

Photography and Architecture.

By E. M. Cosgreave. Bradford: Percy Lund & Co.

Mr. Cosgreave is an enthusiast in the photography of ecclesiastical architecture, and his booklet, the sub-title of which is, "How each lends interest to the other," contains forty-three illustrations from his architectural photographs. A few hints to the photographer contemplating this kind of work are given, and the various styles of church architecture are illustrated and described. It is an unpretentious, but, nevertheless, useful little book.

La Photographie durant l'Hiver.

By L. Mathet. Paris: Charles Mendel.

M. Mathet's work is directed to pointing out the great field photography offers for cultivation during the winter months, and incidentally it is a capital guide-book to the main subject, prominence, of course, being given to the influence which a fall in the temperature exercises on photographic economics. Collodion, as well as gelatine, work comes in for treatment.

The Grammar of Photo-engraving.

There is just now much demand for information relating to photo-reproduction processes, and this, no doubt, explains the importation of this work. It is, in fact, an American work, dealing, to quote the title-page, with "drawing, chemistry, and optics as applied to photo-engraving," and claiming to be "a practical treatise on the art of half-tone, zinc etching, swelled gelatine, lithotype, and chalk-plate engraving as practised in the United States." The book is replete with useful, and, so far as we have been able to gather, accurate information relating to photo-engraving, and as such will, doubtless, find its way to the studios of many process workers.

Pictorial Photographs: A Record of the Photographic Salon in Twenty Plates. Reproduced in Photogravure.

By W. L. Colls. London: Walter L. Colls, Castlenau-gardens, Barnes; or Kegan Paul & Co., Charing Cross-road.

This collection of photogravures, the work of Mr. W. L. Colls, has been happily chosen, as it includes examples of the various "schools" that contributed to the last Exhibition of the Salon, although possibly there is an unnecessary preponderance in favour of foreign workers. Among the twenty pictures selected for reproduction may be mentioned Henneberg's *At the Rushy Pool*, H. P. Robinson's *In Kilbrennan Sound*, Sutcliffe's *Fog*, Craig Annan's *A Little Princess*, Horsley Hinton's *Day's Decline*, Striglitz's *Scurrying Home*, Demachy's *Rouen*, &c. It goes without saying that Mr. Colls' photogravures are capitally done, and he has, in most cases, very successfully reproduced the colours of the originals. If we demur to the implied theory of the preface that modern pictorial photography is only to be dated from 1893, we none the less recognise this collection of pictures as one of which not only the Salon and Mr. Colls, but photography itself may be proud.

News and Notes.

Royal Photographic Society.—Technical Meeting, January 28. *Dr. Rudolph's Method of Lens-testing and some of his Results*, by Mr. J. H. Agar Baugh. *Stereo-micrographs with New Colour-tone Effects*, by Mr. Fred Iles.

We have to record the death, at Ilfracombe, of Mr. W. Harding Warner. The name of Mr. Warner will be familiar to many of the readers of this Journal and its Almanac, to both of which he was a frequent contributor. Essentially one of the old school in matters photographic, Mr. Warner was endowed with considerable ability.

Photographic Club.—The next weekly meeting of the Club will be held in the Club-room at Anderton's Hotel, Fleet-street, E.C., at eight o'clock on Wednesday evening January 29. Travellers' Night. The *Avon Valley*, illustrated by lantern slides from negatives taken by the lecturer, Mr. Harold Baker, of Birmingham. Visitors are always welcomed by the members.

Leeds Photographic Society.—The first meeting of the new Committee was held at 12, East Parade, when the officers for the current year were elected as follows:—*President:* Mr. Peter Gilston, J.P., ex-Major.—*Vice-Presidents:* Messrs. John H. Walker and Herbert Denison.—*Hon. Librarian:* Mr. J. C. P. Atkinson.—*Hon. Lanternist:* Mr. A. W. Atkinson.—*Hon. Treasurer:* Mr. Alfred Naylor.—*Hon. Secretaries:* Messrs. Alfred Naylor and Thomas Coombs; these, together with Messrs. Godfrey Bingley, B. A. Bussell, F.I.C., and R. W. Savage forming the Committee for 1896. It was arranged the opening meeting of the session should take the form of a social gathering, members and one friend to be admitted free, the reception to take place in the Board-room of the Leeds Mechanics' Institute at a quarter to eight p.m. Coffee and light refreshments provided. President's address at a quarter past eight in the Society's room, the remainder of the evening to be spent in an exhibition (by limelight) of slides, procured by Mr. J. H. Walker. The Annual Lantern Exhibition is fixed to take place on February 6, in the Albert Hall. In past years these have been much appreciated by local lovers of art and photography, between twelve and thirteen hundred tickets being issued by the members of the Society to their friends. It consists chiefly of the work done during the past year, about 600 slides usually being sent in to the Selection Committee, from which the requisite number are chosen. We have no doubt the programme on the 6th prox. will be a good one, several of the members of the Leeds Photographic Society having taken medals at the photographic Exhibition held last autumn in the Municipal Art Gallery. Some remarks have been applied to this Society suggestive of a petrified condition, but the Committee, while not endorsing any statement to this effect, are earnest in their endeavour to make all connected with it and the Convention meetings in our city this year a success. The Convention Committee has commenced a subscription list in connexion with the local expenses, and have already had several hearty responses. We hope for and will help so fair a start to a good finish.

THE Moonlight Patent Lamp Company, Liverpool, notify us that their telegraphic and cable address has been altered from "Iredale, Liverpool," to "Moonlight, Liverpool."

WE are asked to state that the *Englishwoman* is publishing a series of photographs of beautiful young Englishwomen, and the editor of that magazine will be glad to receive from amateur or professional photographers suitable pictures for reproduction. A fee will be paid for all photographs published. Photographs should be addressed to the editor of the *Englishwoman*, 125, Fleet-street, London, E.C.

BOSTON CAMERA CLUB.—Established January, 1894. Meetings are held at Shodfriar's Hall, Boston. *President:* Rev. W. FitzHarry Curtis.—*Vice-President:* Mr. W. H. J. Wood, M.R.C.S., L.R.C.S.—*Committee:* Rev. H. Curtis, Messrs. J. Best, A. R. Beaumont, G. Warner, and H. Wood.—*Treasurer:* Mr. C. G. W. Phillips.—*Secretary:* Mr. A. Hopewell Smith, M.R.C.S., L.R.C.P., L.D.S., Linden House, Boston, Lincolnshire.

CARDIFF PHOTOGRAPHIC SOCIETY.—An International Photographic Exhibition of photographs, photographic apparatus, and appliances and photographic processes will be held in a specially erected building in Gathays Park, Cardiff, in conjunction with the Cardiff Fine Art, Maritime, and Industrial Exhibition. The Exhibition will open early in May, and continue open for a period of six months or thereabouts. The Honorary Secretary is Mr. T. H. Faulks, 127, Bute-road, Cardiff.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

January.	Name of Society.	Subject.
27	Camera Club	*Photo-micrography.* T. Charters White.
27	Croydon Camera Club	Rehearsal of Members' Slides to be shown on the 29th.
27	Richmond	*My Camera, Hand and Stand, and How I Use it.* The President.
28	Birmingham Photo. Society	Demonstration upon the Manipulation of the New Enlarging Lantern. Messrs. W. Bateman and C. S. Baynton.
28	Brixton and Clapham	*Elementary Photo-micrography.* R. G. Mason.
28	East London	*Composition, and Light and Shade.* E. Atkinson.
28	Hackney	Open Night.
28	Royal Photographic Society	*Dr. Rudolph's Method of Lens-testing and some of his Results.* J. H. Agar Baugh.—*Stereomicrographs with New Colour-tone Effects.* Fred. Iles.
29	Borough Polytechnic	*Photographic Apparatus.* T. F. Bunce.
29	Croydon Camera Club	*In Eastern Lands (Tunis and Egypt).* Ernest R. Ashton.—Members' Slides.
29	Leytonstone	Members' Lantern Evening.
29	Photographic Club	*The Avon Valley.* Harold Baker.
29	Newton Heath	Social Evening and Lantern Exhibition.
30	Ashton-under-Lyne	*What is a Picture?* Charles Taylor.
30	Bradford	Second Annual Social.
30	Camera Club	*Nature's Method of Correcting Astigmatism, &c.* Dr. Lindsay Johnson, M.A.
30	Leeds Camera Club	*Toning of Platinotype Prints.* Rev. J. Beanland.
30	Leigh	Lantern Evening.
30	Liverpool Amateur	*The Golden Valley and the Black Mountains, a Holiday in King Arthur's Country.* Dr. J. W. Ellis.
30	Oldham	*Amongst the Dutch.* S. L. Coulthurst.
31	Birkenhead Photo. Asso.	*The Carbon Process.* Mr. Rae.
31	Bournemouth	*Photo-ceramics.* W. Etheltert Henry, C E.
31	Croydon Microscopical	Conversational Meeting.
31	West London	*Through County Donegal with a Camera.* G. Lamley and H. Selby.

ROYAL PHOTOGRAPHIC SOCIETY.

JANUARY 21,—Photo-mechanical Meeting,—Mr. T. Bolas, F.I.C., F.C.S., in the chair.

Mr. E. SANGER SHEPHERD read a paper on

IRREGULAR GRAINED SCREENS.

He said that, of the methods at present adopted for producing an irregular grain, probably that most used was transferring from a collotype plate to stone; but by this means one was never sure of getting any particular grain, whereas, if the grain was in the screen, one could select a grain suitable for the subject, and, on developing the negative, the result was seen at once. The irregular-grained screen which he recommended was used in much the same manner as a cross-line screen, *i.e.*, placed a short distance in front of the plate in the camera, and he had found that good results might be obtained by either the wet or dry-plate process, but the distance from screen to negative must be less than in the case of the cross-line screen. The screen was made by flowing an aquatint ground over a sheet of glass, etching with hydrofluoric acid, then repolishing the glass, and filling in with printing ink, and such screens were practically permanent, as, in case of damage by access of nitrate of silver, &c., the ink could be removed and the etched parts refilled. These screens could be used in three ways: the etched screen as described might be used, and this was the most useful form; a copy of it on a dry-collodion plate, which was liable to stains, and other disadvantages; or a bitumen grain could be laid on the grain and heated, but this is only useful for photo-lithographic work. Other methods of utilisation were to first expose a dry plate under the screen, afterwards exposing to the subject to be copied; or to print from a negative on autotype tissue, and then expose the tissue in contact with the screen. The screens could be made in large sizes, and were applicable to the poster work; they were also very useful in photogravure. His experience was that "devils" were due to impurities in the copper plate, generally iron. He had found it difficult to obtain samples of hydrofluoric acid suitable for etching, it was not strong enough. He had tried very many forms of resist, but none would stand the action of the acid for more than about three-quarters of a minute.

The ASSISTANT SECRETARY (Mr. Child Bayley) suggested the addition of ammonia to the hydrofluoric acid.

Mr. SHEPHERD said the use of fluoride of ammonium caused a ragged, instead of a clean, line, but with hydrofluoric acid the lines were clear and brilliant. There was, however, considerable difficulty attending the production of irregular-grained screens, more so than with etched line screens. He believed ruled screens would be less expensive.

Mr. LEON WARNERKE referred to the use of the dusting box, but

Mr. SHEPHERD said the dusting box was one of the most aggravating tools it was possible to use.

Some discussion took place with regard to various means of securing a uniform grain by means of dusting asphalt, at the conclusion of which a vote of thanks was passed to Mr. Shepherd, who exhibited a number of screens, negatives, blocks, and prints in illustration of his remarks.

PROFESSOR RÖNTGEN'S DISCOVERY.

Mr. J. W. GIFFORD, of Chard, exhibited some results which he had obtained in photography by the invisible rays of a Crookes radiant-matter tube, upon the lines of Professor Röntgen's recent investigations. He detailed his method of procedure, from which it appeared that, having set up the radiating tube, he placed a very rapid dry plate in a wooden box, situated at a distance of three inches from the source of radiation; a child then held his hand between the box and the tube, and an exposure of five minutes served to impress a very distinct image of the hand, showing indications of the bones and a much clearer representation of the finger nails. A second experiment was then described, similar to the first, except that an ebonite developing dish was interposed between the wooden box, containing the plate, and the child's hand, and it was found that the ebonite offered no obstruction to the radiations, but the ribs at the bottom of the dish appeared to cause a refractive action. The interposition of a thick porcelain dish caused an appreciable obstruction to the rays, and increased the necessary exposure to ten minutes. The next experiment described showed that a somewhat similar effect might be produced without a Crookes tube, the sparking electrodes of a coil apparently emitting similar radiations, by means of which Mr. Gifford obtained an image of a child's hand which was placed outside a wooden box which contained the photographic plate. This looked like an electrical effect, and, although at the present stage of the inquiry he could only speak with the greatest reserve, he thought it might prove that Professor Röntgen's effects were to be explained by electrical induction as set forth in the doctrines of Hertz, as well at least as by regarding them as due to the light and the ultra-violet; perhaps, indeed, we might be on the "No-man's-land" between them. However this might be, the thanks of all photographers were certainly due to Professor Röntgen for having first drawn attention to these effects.

A long discussion ensued with regard to some apparently inexplicable problems with which Mr. Gifford had been confronted in the course of his experiments, and the meeting closed, after a prolonged sitting, with a cordial vote of thanks to him for his most interesting communication. Mr. Gifford's results may be inspected on application to the Assistant Secretary of the Society, at 12, Hanover-square.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

JANUARY 16, 1896.—Mr. Walter D. Welford in the chair.

Mr. H. C. Rapson showed two lenses or combinations of lenses by Ross, both marked No. 2, and wanted to know of what they were parts. It was suggested that they were the back combinations of two portrait lenses for a stereoscopic camera.

Mr. Walker passed round some plates, stripped for examination, and backed with an anti-halation paper, and asked the opinion of the members as to its efficiency.

The question of its perfect optical contact was raised, and it was pointed out that double reflections could be seen through the glass, thereby demonstrating its unsuitableness as a preventive of halation.

COLLOTYPE.

The HON. SECRETARY passed round some collotypes by Mr. Wilkinson, and prints by the photo-autocopyist process, and said that at a previous meeting a question was raised as to the comparative merits of these processes, and he had lent Mr. Wilkinson negatives for this purpose. In the results he noticed there was a certain amount of spottiness in the autocopyist print—not grain, but spots of ink, which he thought an imperfection in the printing method. It was not noticeable in the prints on rough paper, but only on the surface paper. He considered the collotype had the advantage, with which most of the members agreed.

The CHAIRMAN said that, the photo-autocopyist film being so much thicker than that of the collotype, the gelatine might be more liable to attack, and thus cause the defects.

Mr. J. E. HODD did not think that the papers used—one rough and one smooth—conduced to a fair comparison of the merits of the processes. He mentioned a print by the autocopyist of a castle or abbey, which, in his opinion, would take a lot of beating by the collotype process.

The question as to whether rough or smooth paper gave the greater contrast was discussed, but opinions were divided.

The HON. SECRETARY thought the superiority of the collotypes was very largely in the evenness of the prints, and the absence of defects such as spots, &c. One could get a clean print with collotype, but very rarely with the autocopyist.

Mr. J. E. HODD inquired the result of any trials of Cadett's spectrum plate by the members, but nobody seemed to have used them.

STRIPPING NEGATIVES.

The HON. SECRETARY asked for members' experience in stripping negatives

and which was the best process. He had tried one published by Burton, consisting of—

Methylated spirit	2 ounces,
Water	3 drachms,
Hydrochloric acid	1 drachm,

and found that, after an immersion of five or six minutes, the film readily stripped off, remaining almost its original size.

The CHAIRMAN considered that the quality of the water influenced stripping to a large extent. He had noticed that it was most difficult to strip a negative from which a great number of prints had been taken, and inquired the action that rendered the film firmer after excessive printing.

The HON SECRETARY passed round an enlargement of a snap-shot of the late Mr. Traill Taylor, presented by the Chairman, which he considered a very characteristic likeness, and proposed that it be framed with the other decided upon, and hung in the room.

This was seconded by Mr. DRAGE and carried, and a vote of thanks accorded to the donor.

THE WATKINS COMPETITION.

The CHAIRMAN drew attention to the result of the developing competition instituted by Mr. Alfred Watkins, which has been to award the first prize to Mr. B. J. Edwards, who was Watkins's strongest opponent, proving that it is possible to alter the relative gradation of a negative in the development.

Mr. R. BECKETT said he had received two strips from Mr. Cowan, in which he had altered the gradations very much more than a good many had an idea that it could be altered, and without fog.

The HON. SECRETARY said that the experiments, as shown at the Photographic Club, seemed to him a very curious way of arriving at a conclusion. They have judged by the silver print from the negative. He asked whether the scale of gradations in the silver print was the counterpart of the scale of gradations in the negative.

Mr. A. MACKIE pointed out that it was Watkins's own idea to use the print. He agreed with Mr. Edwards that the scale of gradations could be altered.

A long discussion ensued on this point, and on the new discovery by Professor Röntgen.

PHOTOGRAPHIC CLUB.

JANUARY 15,—Mr. E. A. Newell in the chair.

Mr. BIRT ACRES gave a demonstration of his new

KINETOSCOPIC LANTERN.

By means of this instrument, which is Mr. Acres' original invention, he is able to show upon the lantern screen enlarged pictures representing consecutive phases of motion. He showed pictures of the Derby, the course being cleared, the actual race, with the group of horses rushing to the front of the picture and out of it, and the subsequent thronging of the crowd across the course. He also threw upon the screen a series of representations, taken from the life, of three skirt dancers, a boxing match, and a set-to between the boxing kangaroo and its master. In another set of pictures the German Emperor, attended by his little sons, walking up and down the lines of one of the German crack regiments drawn up for review purposes. Mr. Acres' masterpiece, however, is a series representing "breaking" waves on the seashore. The great and striking difference between Mr. Acres' pictures of waves followed by fresh waves, and each breaking with the thousand variations of form which obtain in nature, and the zoetropic semblance of motion followed by identical semblance of motion, is most marked. The Photographic Clubbers present testified to their admiration by round after round of hearty and spontaneous applause. The instruments for showing the pictures and the series of negatives themselves are Mr. Acres' own work. The negative impressions are made at an average rate of thirty to forty per second, on lengths of film of from forty to sixy feet; if necessary, as many as one hundred exposures per second can be made; the size of the original negative is approximately $1 \times \frac{3}{4}$.

Mr. SUNDERLAND then gave an interesting paper upon the subject of the engraving and printing of half-tone blocks, which was followed with interest.

Mr. ISENTHALL showed a camera which he said he believed was the smallest working camera in the world. It was made for taking photographs of the larynx. The lens, which is of a rectilinear form, is by Steinheil, and the plate, which is contained in a minature slide, is one inch square. The camera is fixed and adjusted in the ordinary manner. The pictures, however, are made by reflection from a silvered mirror, the patient's laryax being illuminated by a one-candle power incandescent lamp. The average exposure is about twelve seconds, but some practice on the part of the patient is required to sit for this length of time without movement, as it is said that considerable irritation results from the insertion of the apparatus into the mouth and throat.

Croydon Camera Club.—The meeting on Wednesday, January 15, was a members' Lantern Night, when a large and varied number of slides were shown upon the screen, the best of these being chosen for public exhibition at the Braithwaite Hall on the 29th inst. The following members contributed:—Messrs. Maclean, Watson, James, J. Noakes, A. J. Noakes, Hirst, Rogers, Holland, Myrtle, and Bowen. During the evening the PRESIDENT explained a newly invented automatic photo-printing machine, which prints, develops, and finishes several thousands of prints a day at an estimated cost of about eight half-plate prints for one penny. The image was on silver bromide paper, and he showed a long strip of prints which had been thus printed. Messrs. Gosheron and Morgan were elected members.

Croydon Microscopical and Natural History Club (Photographic Section).—On Wednesday evening, the 15th, twenty-two of the members of this Club availed themselves of the kind invitation of Brin's Oxygen Company to visit their works. Arriving at seven o'clock, they were most courteously received by Mr. K. S. Murray, by whom they were conducted over the whole of the works, and by whom every step in the process of obtaining and

COMPRESSING OXYGEN

was most minutely explained. The process has been so often described, and is so fully dealt with in Mr. Murray's book on *Compressed Oxygen*—a book which, by the way, ought to be in the hands of all users of compressed gases—that it is hardly necessary to recapitulate all the details here. Suffice it to say, that the members saw the working in every stage, from the purification of the air by means of caustic lime and soda, the passing of the dried and purified air into the retorts at a pressure of about ten pounds per square inch, such retorts being charged with masses of porous barium monoxide (obtained by heating barium nitrate), and arranged in a furnace, which is heated to 1300 degrees by means of burning carbon monoxide, a system causing less damage to the retorts and furnaces than direct firing. At the end of five minutes this part of the process stops automatically, and, a series of valves being reversed, the pumps, instead of forcing air into the retorts, create a partial vacuum, and the oxygen which was absorbed by the barium monoxide, converting it into peroxide, is given up, and passes on to the oxygen gas-holder. After another five minutes, this part of the process stops, a reversal of the valves again takes place, and air is once more forced into the retorts, and so on indefinitely. The process of annealing cylinders—*i.e.*, heating them to a dull red heat in furnaces heated also by burning carbon monoxide, and allowing them gradually to cool—was then shown, as also was the testing of them by means of the hydraulic pump, to ascertain that no "permanent stretch" was imparted to the metal. Finally, the filling of cylinders with oxygen at a pressure of 120 atmospheres, or 1800 pounds per square inch, was shown, and, after having spent a most interesting visit of one and a half hour's duration, the members, after according a hearty vote of thanks to Mr. Murray, returned to Croydon.

ON Friday, the 17th, a very crowded audience attended to witness the exhibition on the screen of some 150 lantern slides by Captain ABNEY, who most kindly attended and gave a full explanation of each slide. The views consisted of Alpine scenery in the winter time, and comprised not only such parts of the mountains as are perpetually covered with ice, and the glaciers, but also some remarkably fine effects of snow and hoar frost. Not less remarkable, and certainly not less beautiful, were the cloud effects in these cold and lofty regions. No one who has not visited the Alps, or been fortunate enough to see such a selection of slides as these, can form any clear notion of the splendid, though frigid, scenes there to be met with. A most cordial vote of thanks was proposed, seconded, and carried unanimously to Captain Abney, not only for the use of his slides, but for his kindness in coming down to explain them.

East London Photographic Society.—January 14, Mr. Walter R. Gould presiding.—A lecture and demonstration on

PLATINO-BROMIDE PAPERS

was given by Mr. NAHUM LUBOSHEZ, of the Eastman Company, which was attentively listened to. The examples brought for inspection—some of them measuring about six feet by five feet—were perfect specimens of their kind, and spoke volumes for the capability of the paper. The exposure and development of the paper was thoroughly explained, the lecturer preferring, in place of some of the newer developers, the old-fashioned ferrous oxalate, giving, as his reason for such preference, that, with this developer, the image was more under control, and allowed the operator time to modify the result if necessary, whereas, with the newer kinds, the image flashed up at once, and gave one little or no time to rectify the exposure. The instability of uranium toning for bromide papers was remarked upon, and, for those who were desirous of altering the steely appearance of their prints, he gave the following formula, which would produce a pleasing brown tone:—Hypo, 10 ounces; alum, 1 ounce; water, 80 ounces. To make the bath work quickly, it was advised to heat the solution to almost boiling point, the print first being put in the liquid before the operation commenced, having previously been developed and fixed in the ordinary way. When the toning is accomplished, the solution, with the print still in it, should be allowed to cool, and then the print should be taken out and thoroughly washed. To illustrate his remarks, the lecturer toned a print before the audience, which amply confirmed what he had said. Difficulties which the less experienced photographers are likely to meet with in working these papers were commented upon, and cleared up in a way as to leave no room for future failures.

Hackney Photographic Society.—Mr. E. Puttock in the chair.—A discussion on the question as to

WHETHER NEGATIVES LOST DENSITY

in the fixing bath took place. Mr. HUDSON thought that there was a distinct loss when fixing out negatives which had been developed with eikonogen. Mr. HENSLER thought that the loss in density was more apparent than real, arising from the increase of transparency by the fixing out of the bromide of silver, &c. Mr. GARDNER considered that there was a loss, and more so with rapid plates than with slow. Mr. A. BARKER had noticed it in cases of under-exposure, when forced development gave an image seemingly very dense, but which, on fixing out, became a mere ghost. Mr. R. BECKETT said that the quicker the development the greater the loss in fixing. There was a difference in the respective actions of old and new fixing baths. The latter caused more loss in fixation than the former, particularly with some brands of plates. He advised instead of using entirely fresh baths, to use a mixture of old and new, they would work much more evenly. Mr. BUTCHER, of Blackheath, then showed the capabilities of the firm's incandescent gas lantern. He said that they did not claim that the light was equal to limelight, but was superior to the majority of oil lamps in power, and to all in the qualities of portability, cleanliness, freedom from smell, and comparative coolness. A six-foot disc was illuminated at the meeting, and the light, although by no means comparable with the oxyhydrogen, was considered to fully bear out Mr. Butcher's claims.

North Surrey Photographic Society.—Mr. R. W. Wilson, who has fulfilled the duties of Hon. Secretary for the last four years, has, to the great regret of the members, been obliged to resign, in consequence of increased demands on his private time. Mr. W. H. Baldwin, of 49, Christ Church-road, Streatham Hill, has been appointed his successor, and has arranged an attractive programme of demonstrations, competitions, &c., for the new year. The first demonstration of the season was given on Tuesday, January 7, before a large

gathering of members, when Mr. E. CECIL HERTSLET, after explaining Hübl's method of

TONING PLATINUM PRINTS

with ferridcyanide of iron, toned several prints, and then invited some of the members present to do the same. The operation worked with great rapidity and smoothness, the prints acquiring colours varying, in accordance with the length of their immersion in the toning bath, from a pale slate to a bright sky blue. In order to show how completely the print could be restored to its original black, if so desired, Mr. Hertslet considerably over-toned one specimen, after which he easily removed the whole of the acquired colour by immersing it in a bath made strongly alkaline by carbonate of soda. The print was, when rinsed, placed in an acid bath for a few seconds, and then toned again to the proper colour. At the conclusion of the demonstration Mr. Hertslet passed round for inspection a number of prints which he had previously toned, in order that the members might be able to judge the different shades of colour when dry. He said that, as the tone would yield to alkalies, it was not to be expected that the colour would be permanent, unless the prints were framed and glazed, and mounted with a solution which was strongly acid.

Birmingham Photographic Society.—January 14.—The Annual Meeting of this Society was held at the rooms, Exchange-buildings, Sir J. Benjamin Stone, M.P. (President), in the chair. There were also present Messrs. G. F. Lyndon, J. H. Pickard, C. J. Fowler (Hon. Secretary), T. W. Robinson, W. Jones, A. J. Leeson, W. Bateman, G. Thomason, T. Taylor, Underwood, and W. T. Greatbatch. In their eleventh annual report the Council expressed their pleasure in being able to record the continued success and satisfactory position of the Society. The removal to the new rooms chronicled last year had proved beneficial in every way, and had fully justified the Council in taking the responsibility of the experiment. Many excellent papers and demonstrations of a practical nature had been given, together with an instructive discourse upon the artistic elements of photography, by Mr Charles Morgan, of the Birmingham School of Art. Manufacturers of novelties had also favoured them with interesting descriptions of their appliances. The average attendance at technical meetings had been about thirty-five. Seventeen new members had been added during the year. No further Exhibition had been held at the Crystal Palace, so that the Challenge Cup still remained in the hands of the winners for 1893. To meet a generally expressed desire, the Council had had constructed a thoroughly efficient enlarging lantern, fitted with all modern appliances for use with artificial light. The Exhibition was held on May 6, being opened by the President, in place of Mr. Sam. Timmins, who was unfortunately unable to attend. It was, for the first time, open during the whole of the week, and the numerous attendance, in spite of remarkable summer weather, together with the handsome profit made, would justify the experiment being repeated upon similar lines. The Open Classes included rather more outside entries than last year. The quality of the exhibits was good, and showed a distinct advance in the general evenness of the work. The total number of exhibits was 437, from 45 competitors. There were also many excellent pictures kindly lent for exhibition only. The silver Challenge Cup for the highest number of awards in all classes was won by Mr. W. T. Greatbatch, who gained three firsts and three honourable mentions. The HON. SECRETARY of the Warwickshire Photographic Survey Section reported that progress had been made during the year, in that a number of photographs had been handed in to the Hon. Curator, sufficient to fill the frames belonging to the Survey Council. Arrangements had been made for a third Exhibition of the pictures in the Art Gallery in February next, when they would be presented to the Council of the city of Birmingham. This would bring the number of photographs so presented to over two thousand, mainly the gratuitous work of the Survey Section of the Society. The funds of the Section were well in hand. With regard to the excursions, a slightly lower average attendance was secured than in the previous year. The majority of the excursions were, however, very enjoyable ones, and resulted in some good pictures being obtained. The accounts showed a balance of 79*l.* in hand. The CHAIRMAN, in moving the adoption of the report, alluded to its satisfactory nature. The progress of photography was, he said, so wide that, in order to encourage further development, they, as an association, should hold the very widest views and largest sympathies. In their exhibitions the classes should be as wide as possible. Apart from the fact that the members were competing with each other, the outside world looked upon them as representing the photographic world, and everything which was progressive in the art should be brought before the public through their medium. He hoped, therefore, that the Exhibition would become more popular and illustrative of photographic advancement each year. There had been two or three striking developments in the art during the year, particularly in the direction of colour photography and in photographic illustrations in newspapers. In the latter department he thought such societies as theirs might do much to raise the tone of the illustrations. It was impossible to conceive more wretched work than some of that which was published in this manner. He hoped that public taste would make itself felt with regard to those publications which were merely advertisements of artists, &c., and the artistic merit of which was bad. The paragraph relating to the photographic survey of the county was satisfactory so far as it went, but he hoped they might do still more work in that direction. Warwickshire pictures were by no means exhausted yet. There was a great deal to be done in the way of detail, which he hoped would be accomplished in future. He still hoped that the national scheme to survey the country would be taken up before long. He had had a number of letters from most influential people on the subject, urging him to push forward the movement. Mr. PICKARD seconded the motion, which was adopted unanimously. The retiring officers having been thanked, the following elections were made :—*President :* Sir. J. Benjamin Stone, M.P.—*Vice-Presidents :* Messrs. G. F. Lyndon, W. Jones, J. H. Pickard, and G. A. Thomason.—*Hon. Treasurer :* Mr. F. J. Penn.—*Hon. Librarian :* Mr. W. S. Horton.—*Hon. Secretary :* Mr. C. J. Fowler. The proceedings concluded with a vote of thanks to the Chairman.

Bolton Photographic Society.—January 14.—Mr. J. Boothroyd gave a practical demonstration of the exposure and development of lantern plates. The skate-blade cutting board, manufactured by Messrs. R. & J. Beck, was exhibited, and met with great approval.

Bradford Photographic Society.—January 16, Mr. A. P. Rendell in the chair.—Mr. P. R. SALMON gave a lecture, entitled

"MY AIM IN PHOTOGRAPHY,"

in the course of which he pointed out the desirability of working with a purpose and an end in view. The lecturer who was on the syllabus for that evening had, for some reason or other, withdrawn at the last minute, and Mr. Salmon kindly came forward to fill in the evening. Although the notice was so short, Mr. Salmon managed to prepare no less than ninety slides to illustrate his remarks. Thirty slides were used to point out the various aims that could be taken up, such as landscape, seascape, hand-camera work, astronomical, microscopical, historical work, &c. The remainder illustrated studies of country life of the Robinsonian type, in which branch the lecturer was aiming at perfection, several slides from Mr. Salmon's negatives including Hood's *Song of the Shirt, Cinderella, Red Riding Hood*, &c., were shown. A vote of thanks, proposed by Mr. O. Nicholson and seconded by Mr. W. Booth to Mr. Salmon, and also to Mr. W. Harnsworth, of Appleton & Co., for manipulating the Club's lantern, were passed unanimously.

Darwen Photographic Association.—January 16, the President (Rev. Henry Irving) in the chair.—A number of slides, kindly lent by Messrs. R. W. Thomas & Co., photographic dry-plate manufacturers, were projected on to the screen, comprising many very difficult subjects of Westminster Abbey, exteriors and interiors of all the leading cathedrals, Windsor Castle, St. George's Chapel, and the Albert Memorial Chapel, Windsor; the Royal Mausoleum, Frogmore, and many other places of interest. To photograph the two latter places Messrs. Thomas & Co. have had to obtain special permission from her Majesty, and it is believed that the slides which this firm have in circulation are the only ones extant. The views were taken on Thomas's anti-halation plates, and the beautiful definition obtained in the high lights and also the quality of the lantern slides speak well for the plates on which the photographs were taken.

Dewsbury Photographic Society.—January 14.—The Secretary was kept fairly busy entering new members and taking subscriptions. He announced that the February meeting would be filled by the showing of some prize slides, and the March meeting by other prize slides. The Society's quarterly competitions were eagerly discussed by the members, most of whom said they should compete. The handing round of specimen copies of a paper which was well spoken of by those who already took it, and a discussion on lenses, by the Secretary, Mr. E. Human, and Mr. Earl, brought a very enjoyable evening to a close.

Leeds Camera Club.—The optical lantern, or, to give it its more popular title, the "magic" lantern, possesses such a power of fascination for old and young alike as almost to justify its better-known name. Most particularly amongst photographers is this the case, and the lantern and camera may fairly be looked upon as twin sisters. It will be readily understood, therefore, that Mr. R. BOURKE's demonstration upon

"THE OPTICAL LANTERN AND ITS USE"

on Thursday last had been looked forward to by the members of the Leeds Camera Club with considerable interest Nor were their expectations in any way misplaced, for Mr. Bourke furnished them with a most instructive series of experiments, and his lecture throughout was brimful of useful hints on lantern matters. After describing the construction and optical system of the lantern, the demonstrator dealt fully with the oxy-hydrogen light for the lantern, which he recommends for all purposes in preference to oil. Using both single and biunial lanterns, Mr. Bourke lucidly explained the principles of the light, using oxygen under pressure in cylinders, and hydrogen (coal gas) from the mains; he showed the use of the pressure gauge for ascertaining the contents of a gas cylinder, and also the advantages of employing a suitable regulator for the supply of the gas to the jets. A comparison was made between the light intensity through an ordinary blow-through jet and the Ejector jet, much to the advantage of the latter. The Optimus safety etho-oxygen saturator was also tested, and proved very satisfactory, the light being considered by many lanternists present to be quite equal to that of a oxyhydrogen mixed jet. Experiments were also made with the incandescent gas burner for lantern use, but the results were not very encouraging, the mantles being pronounced too fragile for the purpose. Mr. Bourke exhibited several novelties in lantern accessories, including an improved slide box of his own design, and at a late hour was accorded a hearty vote of thanks for one of the most practical and useful lectures of the session.

Liverpool Amateur Photographic Association.—Owing to ill health, Mr. Anyon was unable to give his demonstration on bromide printing, which had been arranged for Thursday evening, the 16th inst., but his place was taken by Mr. H. W. SEARLE, who gave a demonstration on the

A B C DEVELOPER FOR GELATINO-CHLORIDE PAPER,

by the aid of which prints can be obtained on ordinary printing-out paper after an exposure to a short length of magnesium ribbon. Mr. Searle went through the whole process of printing, developing, toning, and fixing in the presence of the members, the development occupying less than three minutes. Two different samples of paper were used, the results in each case being very satisfactory. All the operations can be conducted by ordinary gaslight, no dark room being necessary.

Edinburgh Photographic Society.—January 8, Mr. J. C. Oliphant, M.A. (President), in the chair.—Thirteen new members were enrolled. A number of slides, kindly sent by R. W. Thomas & Co., illustrating the value of their anti-halation plates, were shown. Mr. PATRICK (Vice-President) spoke of the death of Mr J. Traill Taylor, and it was agreed to notify the reference in the minutes of the Society. The Lothian stereoscope was then shown by Mr. A. H. Baird, the inventor, who is a member of the Society. It was explained that with this form of stereoscope any observer can adjust the centres of the lenses to suit himself, and that the design of the instrument allowed the eyes to come close to the lenses.

FORTHCOMING EXHIBITIONS.

1896.
February 27-29 ..... Woolwich Photographic Society.
March 2-6 ..... *South London Photographic Society. Hon. Secretary, Charles H. Oakden, 30, Henslowe-road, East Dulwich, S.E.
" 3-6 ..... *Cheltenham Amateur Photographic Society. Philip Thomas, College Pharmacy, Cheltenham.

"NEGATIVE PAPER."

To the EDITORS.

GENTLEMEN,—Kindly allow me to add my wishes to the request for a revival of the above. I have a roll-holder, which I have not used lately, but would gladly put it into use again with paper.

I may state that some years ago I used it with Eastman transferotype paper, and found it very convenient for many purposes in landscape and architectural photography. The great fault was its great slowness and the occasional failure in stripping. The Eastman Company withdrew it from the market, but, I understand, have again put it on sale, vastly improved, and I am therefore going to try it once more.

If they would put it in rolls to suit their holders, and quicken the speed, I feel sure there would be a big demand. It gave remarkably fine detail and gradation, and developed clean and without fog, a great boon for lantern and microscopic work. Surely their great enterprise is equal to this.—I am, yours, &c., J. A. C. O.

SAPIENT SUGGESTIONS.

To the EDITORS.

GENTLEMEN,—Many a wise word is spoken in jest. In your last, "Cosmos," who often has an attack of inspiration, and, like Charles II., never spoke a foolish word, suggests "the conferment of the Honorary Fellowship of the Royal Photographic Society on Mr. H. P. Robinson, Mr. A. Maskell, or" (it should be "and") "Mr. G. Davison; the admission of the Linked Ring to Affiliation; the bestowal of the Progress Medal on Dr. Burton Coxe; the increase of the Assistant Secretary's salary to 1000*l.* a year."

It is claimed that the Society has greatly improved since the three gentlemen mentioned retired from it. If the improvement was due to their secession, it was therefore due to them; but they have done more than that—although they left not too amicably, they have been constant objects of admiration and imitation by the Society in all matters, except, perhaps, the mechanical hanging of the Exhibition, of which they do not understand the science, and resort to all sorts of dodges and artful massing of pictures so that they shall be seen.

I don't know about Dr. Burton Coxe. I am afraid he tries to be reasonable, which never succeeds; but the last proposition, I am sure, would meet with the approbation of every member of Council who did not see a better way of disposing of the increased income in other pockets than the genial Secretary's. The money came easy. There was a large profit on the goods for which it was paid, and, if we may judge by the proceedings in the past, there is no better way of disposing of it yet proposed or discovered. There is only one question to consider? Is 1000*l.* enough? Don't let us be mean.—I am, yours, &c., AN OLD MEMBER.

METOL.

To the EDITORS.

GENTLEMEN,—I have been using metol for several months, and shortly before the end of last year my skin began to peel off in scales, and the inflammation going under the finger nails caused great pain, that I got alarmed, and wrote to Mr. J. Hauff as to his advice what would be the best cure.

As I had seen in your paper that others had suffered from the same cause, I think it best in the interests of humanity to send you the letter, and ask you to kindly make it known as being the maker's own views. I feel it would be a great pity if the valuable developer metol were compelled, through its one defect, to take a back seat.—I am, yours, &c.,
Oelsnitz, January 1, 1896. E. S. DOUGHTY.

[TRANSLATION.]

TO MR. E. S. DOUGHTY.

Oelsnitz.

IN reply to your letter of yesterday, I beg to inform you that it is possible that metol may affect very sensitive skins. I am, unfortunately, not in the position to give you an absolutely certain remedy for this trouble, but can only advise you to observe the greatest cleanliness when using it, and to rub the hands well in with vaseline, and then dry them before beginning to develop, and then after finishing to wash the hands immediately.

By observing these precautions I feel sure you will not be troubled with this unpleasantness again. Yours very truly,
(Signed) J. HAUFF.

THE PRODUCTION OF STEREOSCOPIC EFFECTS.

To the EDITORS.

GENTLEMEN,—IN THE BRITISH JOURNAL OF PHOTOGRAPHY, early in the year 1895, the present writer, whilst dealing with a kindred topic—the initial stage of composite portraiture—drew attention to the results produced by the superposition of two similar negatives, slightly differentiated in position. Some details were also given of the mode by which this purpose might be satisfactorily effected. He expressly noted that the resultant appearances were stereoscopic, and the phrase employed was varied, by designating it as presenting a "medallion-like appearance." In his experiments, the writer did not fail to note that, when the interior outline differed in depth of tone from the outer, the effect was enhanced, such variation being in some degree equivalent to a difference of tint.

With a view to secure the more complete results which have been recently aimed at, the writer would here take occasion to point out that the employment of the paraphernalia of coloured spectacles, with eye-glasses tinted differently, and supplied separately to each spectator, is a somewhat burdensome complication, and is not without remedy. The purpose would certainly be better served by the provision of one or two coloured lenses, rotating upon their axes, and at such sufficient speed as should flash the alternate illuminants upon the picture, so as to adapt themselves to the correspondent retaining power of the retina. In this manner the suffused intermittent lights would mask momentarily the medley of colour presented by the picture, whilst the lifelike impression of rotundity which is desired would be duly conferred.—I am, yours, &c., W. MATHEWS.
Clifton, Bristol.

ILLINGWORTH *VERSUS* DRAYCOTT.

To the EDITORS.

GENTLEMEN,—With your kind permission, I take this opportunity of thanking my numerous correspondents for their letters of sympathy and congratulation. As they are from all parts of the kingdom, it almost seems unanimous, and it is gratifying to know that so many of the profession agree with, and confirm, the Judge's summing up and the finding of the jury.—I am, yours, &c., WM. ILLINGWORTH.
Clifton Cottage, 168, *Heathfield-road, Handsworth, Birmingham, January* 21, 1896.

ANNUAL LADIES' NIGHT OF THE PHOTOGRAPHIC CLUB.

To the EDITORS.

GENTLEMEN,—I beg to inform you that the Annual Lantern and Musical Entertainment (Ladies' Night) will take place at Anderton's Hotel, Fleet-street, on Wednesday evening, February 12, 1896, at eight o'clock.

As on previous occasions, in order to ensure the comfort of the visitors, the Committee has decided to issue only a limited number of tickets; also that admission for both members and visitors shall be by ticket only. Tickets will be sent only to those members who apply for them.

It is desirable that as many members as possible should contribute slides on this—the most important lantern meeting of the season; so, if members have any they would like exhibited on the occasion, they are requested to send them to Anderton's Hotel not later than Wednesday, February 5, that a suitable selection may be made.

At the end of the present month, the Club will loss the valuable services of Mr. J. A. Sinclair, as Hon. Sec. and Treasurer, and all communications relating to matters arranged to take place after January 31 should be addressed to yours truly. F. A. BRIDGE.
East Lodge, 55, *Dalston-lane, London, N.E. January* 18, 1896.

CHELTENHAM PHOTOGRAPHIC EXHIBITION.

To the EDITORS.

GENTLEMEN,—I shall be obliged if you will allow me to point out in your columns that entry forms for this Exhibition, to be included in the catalogue, should reach me during the first week in February.—With thanks, I am, yours, &c., PHILIP THOMAS, *Hon. Sec.*
Cheltenham, January 30, 1896.

Answers to Correspondents.

*** *All matters intended for the text portion of this* JOURNAL, *including queries, must be addressed to* "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 2, *York-street, Covent Garden, London. Inattention to this ensures delay.*

*** *Communications relating to Advertisements and general business affairs should be addressed to Messrs.* HENRY GREENWOOD & Co., 2, *York-street, Covent Garden, London.*

PHOTOGRAPH REGISTERED :—

Frederick Argall, High Cross, Truro.—*Photograph of the wreck of the "Cornish Lass" at St. Agnes.*

HISTORICAL.—A. MACDONALD. The best history of the early photographic processes will be found in Hunt's works on photography. They are out of print, but may at times be met with at second-hand bookshops for a small sum.

LANTERN-SLIDE BINDING.—SLIDE. Strips of black paper are sold by all the photographic dealers. They are more neatly cut than you could probably cut them yourself, unless you had proper appliances, and they are inexpensive.

SALARIES.—OPERATOR. It is impossible to answer the query, "What proportion of operators now obtain the salaries referred to last week?" The best houses still pay good salaries for really competent men. They often complain that really first-class operators and artistic posers are not easily obtained even now.

CARBON PRINTING.—T. HILL asks what is the reason that he cannot get the printed tissue to stick to the single transfer paper, if it has been kept a few days before it is used? When first received, there is no trouble if used then.—The reason is that the tissue has become insoluble by the keeping. Insoluble tissue will not adhere.

WOODEN DISHES.—T. BRADY asks: "What is the best thing to coat a wooden tray with that has to be used for the silver bath in the wet-collodion process, something that will not be harmful to the solution?"—There is nothing better for the purpose than paraffin wax. The wood must be perfectly dry and warm at the time it is applied.

METHYLATED SPIRIT.—T. ROMER. There is no way of obtaining methylated spirit free from the mineral spirit, except by getting a licence from the Excise in due form. Wholesale chemists are not allowed to sell it, any more than are the oil shops. Even if the licence is obtained, you will not be able to purchase absolute alcohol methylated.

RIGHT TO PHOTOGRAPH.—T. C. W. The caretaker had no right to prevent you from photographing the Abbey from the public highway; it was simply a bit of "bluff" on his part. You should have been more firm at the time. Be so the next time you go; defy him, and, if he touches you or the apparatus, summon him before the magistrates for assault.

COLLOTYPE.—X. A. B. A properly constructed drying box is absolutely necessary. A very important feature of the successful working of the collotype process is the drying of the plates—the time and the temperature. If you are handy at carpentry, you can construct one for much less than the price quoted. The design given in the book is a very good one.

SOCIETY FOR ASSISTANTS.—PHOTO says: "Will you kindly inform me if there is in existence a Benevolent or Protectiou Society for photographic assistants? if so, where to communicate." In reply: Alas! no, "Photo;" there is no such Society. You are one of scores that have put a similar question to us. Why do not you and they start a society which seems so much needed?

ACETYLENE.—A. B. WILSON says: "I have read the article in SUPPLEMENT of your paper on above, and have tried to get quotation in London for the calcium carbide, but have failed. Would you say where it can be bought and means of getting it? if the railway carrier will only carry it under special conditions? Your kind answer will greatly oblige."—Write Messrs. Harrington & Co., 53, City-road, E.C.

SATZ LENS.—L. MELDON says: 1. "What is the new Satz anastigmat I see mentioned on page 39? and, 2, in what does it differ from the Goerz? 3. Who makes it?"—In reply: 1. The Satz is, briefly, a system for providing a series of lenses of different foci in one sitting. See pages 46–52 of the ALMANAC for 1896. 2. The Goerz is a symmetrical doublet, each combination being composed of three lenses; 3. Messrs. Ross & Co. are the makers in England.

WINNERS OF PHOTOGRAPHIC PRIZES.—W. H. K. says: "Will you kindly inform me if there is a work published which gives the names of the winners, also a description of the titles of the photographs that have been awarded medals at the different photographic exhibitions held in this country?"—In reply: No such work is published. The information you require can only be obtained by diligent searching through the back volumes of the photographic journals.

QUICK LENS.—W. PAGE wishes to know what is the quickest lens made? He says he wants the quickest lens possible for taking street views of small size, about two and a half inches square. The most rapid lenses made are what are known as the baby lenses of the Petzval type. They are not well adapted for the work required. What we should recommend is one of the rapid stereoscopic lenses. They have a ratio of *f*-4, and will cover a small plate with the full aperture.

REMOVING SILVER STAINS.—W. J. HERBERT says: "In looking through your valuable book, THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC, a few weeks back, I came upon a solution for removing silver stains on the negatives, sold by one of your advertisers. This last week I have had two or three negatives spoiled with the paper sticking to negatives. I have looked through the JOURNAL again, and I cannot find the advertisement."—In reply: Messrs. Marion & Co., Soho-square, supply such a solution.

GLASS POSITIVES.—ITINERANT.—Any work on photography of twenty year ago will give you the desired information about glass positives; so will the article on *Wet Collodion* in the ALMANAC for the current year.

LENS.—J. SIMPSON. "1. Would a No. 5D Dallmeyer lens, 12×10, be suitable for general studio work, *carte-de-visite* up to 12×10 groups—studio is twenty-nine feet long—or would I require to have a portrait lens suitable for *cartes-de-visite* and cabinets as well? 2. Would 5D Dallmeyer lens be rapid enough for all-round studio work?"—In reply: 1. The lens would be of too long a focus for *cartes* or cabinets. If a cabinet lens be obtained, that may, in that length of studio, be used for *cartes* as well. 2. Yes.

VARNISHING.—B. writes: "Can you please tell me how to prevent matt varnish, which it is desired to keep on the back of the plate, from running on to the gelatine film. I have tried tallow on edges of plate as well as indarubber solution, but have never succeeded in keeping the film side free from the varnish."—There should be no difficulty in the matter. Simply pour the varnish on, as with collodion, and flow it over the plate, taking care that it does not run over the edges. A little practice (very little) is all that is required.

FACSIMILE.—T. H. says: "I should feel obliged if you could inform me in your 'Answers to Correspondents' whether there is any process for reproducing writing in facsimile—one not taking too much time or requiring a press. The purpose for which it is required is for printing names, &c., on the back of prints."—Photo-lithography would be the most practical way, but that will necessitate a litho press; but they are not expensive, if of small size, and are purchased second hand. A negative could be made of the writing, and printed from, and the print mounted on the back of the photograph.

CLUB RULES.—F. DREW (Sheerness-on-Sea) says: "I am taking the liberty of writing you, asking you to send me a sample card or two of rules and prices of printed matter, &c., connected with a club. We are now trying to form a club; have no rules drawn up yet, and should like to see some rules of other clubs. I have no doubt you have printed some for others."—In reply: Write to the Secretary of the (London) Photographic Club, Mr. J. A. Sinclair, 26, Charing Cross-road, W.C., asking him to oblige you with a copy of the Club's rules. These rules have, we believe, formed the basis of many photographic societies' rules.

SHORT WEIGHT (?).—SALOP writes as follows: "I bought two ounces of silver nitrate at an apparently respectable chemist's. I used it four drachms at a time, and when I got to the last four drachms I found it only weighed a little over two drachms instead of four. Ought not this cheating to be exposed? Here is the label with the address of the chemist."—Our correspondent may subdue his wrath, as there is no fraud in the matter. Nitrate of silver is sold by avoirdupois weight, 437½ grains to the ounce, and he has weighed it out by apothecaries' weight, sixty grains to the drachm; consequently there are but fourteen drachms and thirty-five grains in two ounces of nitrate of silver.

COPYRIGHT.—S. R. M. says: "When I took this business, I, of course, bought all the negatives taken by my predecessor; some few of them he made copyright, but the majority of them he did not. An illustrated paper has pirated one of the latter. I have now registered the copyright at Stationers' Hall, and written to the paper asking for a guinea, and threatening proceedings if it were not sent at once. They coolly write back, some days after, saying they have made inquiries, and find that I have no copyright in the picture, and am attempting to obtain money from them that I am not entitled to. Kindly tell me the quickest way to bring them to book, as I will not be done by them."—What the paper says is perfectly correct. You have no copyright in the picture whatever. You are not the author of the work, as the picture was taken by your predecessor. You have no remedy at all.

PROCESS BLOCKS.—A. HOYLES asks: "Will you be good enough to inform me *re* the following:—1. Would it be worth while for, say, a dozen or so half-tone blocks that I require, to take up the process myself? A block-maker would do the twelve for 6*l*. 2. Can you give me a vague idea as to cost of necessary apparatus? I have ordinary studio and field cameras. I suppose these could be utilised? 3. I have read with interest an article in the ALMANAC this year by W. A. Whiston, F.C.S., entitled *Half-tone Work for Amateurs*. Would you be good enough to give me this gentleman's address, as I should like to correspond with him on the subject?"—Reply: 1. If the blocks can be obtained from a professional block-maker, it would certainly not be worth while to learn the process expressly to make them yourself. It would be false economy. 2. Write to Messrs. Penrose & Co., Upper Baker-street, W.C., for their price-list. 3. If you send the letter to us, we will address it and post it on. We do not give private addresses in this column.

HAND CAMERA.—HUNTSMAN says: "I am in want of a hand camera for the purpose of photographing the hounds and hunters and the various local meets. The lens should be very quick, and give a good definition. Would a ——— lens be the most desirable? I should like to be able to photograph while in the act of leaping. The camera should be small, and give a quarter-plate picture, or nearly so, and would a focal-plane shutter be best? Are you in a position to recommend a special maker by name or the name of his camera? I have not had any experience with a hand camera, and I am not familiar with any of the hand cameras in the market; they are so numerous and confusing that it is difficult to select."—In reply: We do not institute comparisons between the goods of one maker and those of another. For the kind of work our correspondent is about to undertake we should select a magazine focussing hand camera, with a flat field lens working at *f*-7 approximately, and a shutter whose maximum speed was not less than one-one-hundredth of a second. Our correspondent will find several hand cameras answering to the description here given advertised in our last ALMANAC.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 1865. Vol. XLIII.—JANUARY 31, 1896.

Contents.

EX CATHEDRÂ.

One-man shows at the Camera Club were, some years ago, very popular both with exhibitors and visitors. Several good men had opportunities of displaying their work in its progressive stages, and lovers of photography had the exceptional advantage, which is of course denied them at an ordinary photographic exhibition, of studying the entire range of a man's photographic sympathies—and his limitations. We do not know whether these "shows" had to be dropped for lack of available material upon which to draw, or because the executive of the club has not considered it worth while to continue them.

* * *

However, although no public announcement has been made of the fact, there has been on view for some weeks, at the Camera Club, a one-man show by Colonel Gale, who contributes nearly a hundred of his works, so that possibly there is an intention on the part of the Club to resuscitate these happy and pleasant little exhibitions. We think we could supply the Club with the names of at least half a dozen men who, during the last few years, have "come on" sufficiently in their work to deserve the compliment of being invited to contribute.

Of Colonel Gale's work it is not here necessary for us to speak critically or in detail. Who does not know it, and, knowing it, does not recognise it as evincing artistic charm, produced by what is called, now and then, pure photography? Gale is equally at home in a sheep pasture or with a ploughing team, at a cottage doorway, on the Thames, or at a river-side quay. His effects strike one as being obtained without trickery; there is definition and detail present where the impression produced may partake of the nature of "breadth," and equally so where atmosphere has been introduced. Then, the care and attention he gives to the technique of his art, the accurate focussing and definition, the correctness of exposure, and the conscientiousness of his printing—are not these so many object-lessons to the young photographer in danger of being persuaded that the cultivation of photographic art is bound up with diffusion of focus and other fads? Colonel Gale's one-man show is well worth visiting and studying.

* * *

We are indebted to our contemporary *Nature*, of January 23, for Mr. Arthur Stanton's translation of Professor Röntgen's paper descriptive of his experiments with what he calls the X rays. Two of the Professor's photographs referred to in the paper are also reproduced by *Nature*, as well as one by Mr. Campbell Swinton, illustrative of that gentleman's experiments.

* * *

Mr. Alfred Watkins draws our attention to his Relative Speed List, which is published by Messrs. R. Field & Co., of Birmingham. The speeds given, to quote from the card, are "approximate only, for use with the Watkins exposure meter, compiled from actual daylight camera tests (pyro-soda developer)" by Mr. Watkins himself. English and American plates, lantern plates, and bromide papers are here "speeded," and the card, which is sold for twopence, is frequently reprinted so as to keep up with changes.

* * *

Speaking of this card, Mr. Watkins says: "It, of course, only gives the result of individual judgment, but great pains are taken, and I think it is useful to those who do not use meters." Doubtless this is so. Here and there we note that Mr. Watkins's figures quite square with our own experiences with certain brands of plates in the camera, and where we are not in accord with him the differences between us are not fatal. On the whole, this little card is calculated to be distinctly

helpful in enabling one who has to work with a variety of brands of plates to gauge, approximately, the exposures required.

* * *

Albumen paper certainly dies very hard. It might be thought that at such a late period, with gelatine and collodion papers disputing for pride of place, nobody could be found with so much confidence in the successful future of albumen paper as to embark afresh in its preparation and sale. The Electric Photo Company of 30, Fleet-street, however, are so moved and in sending us a sample of a new paper for trial they remark: "Before putting it on the market, we have pleasure in submitting to your notice a sample of our sensitised albumen paper, the qualities of which may, we hope, do something to prevent the use of this hitherto popular class of paper being discarded. The paper itself is the very best Rives, and is doubly coated with egg albumen, so that it is quite free from smell. The sensitising process is conducted with the utmost care in every detail, with the result that a paper is produced which is rich in silver, prints quickly, tones easily and of any desired colour. We claim for it that it is thoroughly reliable and economical both of time and material in working. With it can be produced prints as pleasing and as permanent as it is possible for a silver print to be."

* * *

We hope to take an early opportunity of trying the new paper. Without desiring to institute comparisons between albumen and gelatine or collodion we are, undoubtedly, of opinion that, if up to within four or five years ago the qualities of most of the commerical albumen papers had been what the Electro Photo Company desiderate in their letter, very many photographers would not have given up using it. There are features in good albumen prints which compel admiration for the process and are not always possessed by other methods of printing.

* * *

The Thornton-Pickard Manufacturing Company, Altrincham, send us a book of photographs showing the different departments of their works. The views, which are admirably executed and appear to be collotypes, depict the woodworking machinery shop, the cabinet-makers at work, the metal-workers, the brass finishers, shutter fitters, the examining and finishing room, the general office. Not merely as illustrating, step by step, the evolution of that universally admired specimen of mechanical ingenuity, the Thornton-Pickard shutter, but also as giving evidence of the enterprise and success of the firm, these photographs are interesting to a degree.

* * *

The Company also forward us their latest catalogue, a handsomely printed booklet, in which their specialities are fully described. The Ruby camera has been improved in several details, and is now made so that it can be used either as a hand camera or on a tripod. The camera is so constructed that the half-plate (as well as the larger sizes) can be used for stereoscopic work, in addition to ordinary pictures, if desired.

* * *

The Scovill & Adams Company, New York, write to us: "We regret to announce the death of our late honoured President, Mr. Washington Irving Adams, which occurred at his residence, in Montclair, New Jersey, Thursday, January 2, 1896. We beg, gratefully, to acknowledge the expressions of sympathy and good will which we have already received, and to state that Mr. W. I. Lincoln Adams, who has been our Vice-President, has now succeeded his father in the official position, which he has practically been filling for the past several months, during his father's retirement owing to ill health, so that the management of the business will continue the same as heretofore."—We are sorry to hear of the death of Mr. Irving Adams, whose conduct of the Company, of which he was so long President, was marked by great ability and success. If we mistake not, his son will form a worthy and admirable successor.

THE SULPHOCYANIDES AS FIXING AGENTS.

I.

Sulphocyanide of ammonium has recently being mentioned as a fixing agent for negative purposes in preference to hypo when it is desired to resort to intensification, as is frequently the case after fixing. As the sulphocyanides were tried and found wanting, as applied to positive prints, upwards of twenty years ago, it may be interesting to consider whether the circumstances differ sufficiently to warrant their use for modern negatives. At first sight it would appear, if we look at the relative solubilities of the different silver haloids in hypo and sulphocyanide of ammonium respectively, that the former should be the better agent to employ for proofs in silver chloride, and the latter where negatives or developed bromide prints are in question; but there are other circumstances to consider besides mere solubility.

The great objection to sodium hyposulphite is found in the fact of its being a sulphur compound which very readily decomposes, parting with its sulphur both in the free state as well as in various combinations of more or less doubtful character. The sulphocyanides also are sulphur compounds but it was urged in their favour, when introduced for fixing purposes, that they possess a more stable character than hypo, especially in that they do not part with sulphur in the free state. So far as the last point is concerned the claim is well founded, for, whereas sodium hyposulphite or thiosulphate almost immediately on the addition of an acid, deposits sulphur, this does not occur in the case of the sulphocyanides. But other decompositions occur both spontaneously and under the action of heat or reageuts which scarcely leave the latter salts a better reputation than hypo. For instance, according to Watts the stronger acids decompose the sulphocyanides with elimination of sulphocyanic acid, and this in turn is resolved spontaneously in the cold, and more rapidly at a higher temperature into other compounds including sulphydric acid or sulphuretted hydrogen, as well as carbonic disulphide and ammonia. All the metallic sulphocyanides, we learn from the same source, are decomposed by heat with formation, amongst other compounds, of metallic sulphide.

From this it would appear that the formation of silver sulphide in imperfectly fixed or insufficiently washed films is no less likely to occur when the sulphocyanides are employed than is the case with hypo, at least with the ordinary conditions under which hypo-fixed proofs are found to fade—that is to say, under the influences of time and moisture; although it is only fair to say that, under the action of reagents, the changes that occur are not so rapid nor so apparently injurious in the case of sulphocyanide as of hypo; still the danger lurks about, and should be guarded against.

The real danger seems to us to exist, not so much in the liability of the sulphocyanides to decompose into other and dangerous compounds as to the imperfect way in which they perform the work of fixing. In the course of experiments made upwards of twenty years ago it was found that, although prints fixed with sulphocyanide retained their whiteness—*i.e.*, resisted sulphuration far better and for longer periods than others fixed with hypo, *when preserved in* the dark—yet exposure to light in a very short time caused a degradation of the high lights, showing that the prints had not been perfectly fixed, that is, had not had the whole of the unreduced silver removed from them; and this result was the same, no matter how long the fixing was continued or what strength of solution was employed. It was suggested at the time that this effect was due to the fact that the albumenate of silver, or some other organic compound, formed in the print, was not perfectly soluble in the new fixing agent; but, on the other hand, it was shown, by Mr. John Spiller, amongst others, that in this respect, so far at any rate as concerns the albumenate, that sulphocyanide was superior to hypo; yet the fact of imperfect fixation undoubtedly remains.

The Late Prince Henry of Battenburg.—The death of Prince Henry has caused quite a run on his portraits, and those who are fortunate enough to possess negatives, of recent taking, are doing a good business with them. Apart from being the husband of the Princess Beatrice, he was credited with being a very handsome man, and that, no doubt, has materially increased the demand for his portrait. It may not be generally known that the late Prince was, like some others of the Royal Family, a great lover of photography, and he had a well-appointed dark room at Windsor in which he worked.

The National Portrait Gallery.—It is announced that the First Lord of the Treasury has appointed Mr. Leslie Stephen as a Trustee of the National Portrait Gallery, which is to be opened to the public at Easter, in place of Mr. Gladstone, who resigned the post a few weeks back. It seems a pity that the Trustees cannot be induced to have a department for photographic portraits. As we have said before, in a gallery of national portraits it is the likeness of the illustrious individuals that should be one of the chief considerations, and not whether the portraits be works of art or not. Oil paintings of many who have distinguished themselves in various ways in the arts, &c., are not in existence, yet their portraits would be an acquisition to the Gallery, and photographs might be forthcoming; also, we now have permanent processes for their reproduction.

Photographic Spies.—It would appear that Venezuela is not just now a desirable place for tourist photographers, or, at least, English ones, to visit. A telegram from New York says that a correspondent of the *Herald* was arrested at La Guayra one day last week while taking photographs in the street. He was, however, subsequently released on being identified. The Judge before whom he was taken explained, as the reason for the arrest, that he was informed that many British spies were in the country for the purpose of obtaining photographs of the defences. Had the one arrested been an English traveller, instead of the correspondent of an American newspaper, he would, doubtless, have found himself in an unpleasant position. However, we surmise there are not many English photographic tourists who are likely to visit that district at present. If any do, however, let them beware, for it seems it is an offence even to photograph in the streets.

The Poisons Act Again. — The Pharmaceutical Society (Dublin) at Belfast have been prosecuting the firm of J. Lizars under their vexatious Act for selling an ounce of bichloride of mercury; but here, again, they only succeeded in obtaining nominal damages on one summons, and the two others were dismissed. The magistrates in the sister isle evidently take the same view of the Society's proceedings as do the majority of them in England. One of the features in this case was that the poison was actually sold by a duly registered pharmaceutical chemist; but the prosecution was instituted on the ground that his employers were not pharmaceutical chemists and qualified under the Pharmacy Act (Ireland), and therefore they were said to be liable to penalties for "keeping open shop," &c. Hence it will be seen that, although the chemical branch of a business may be under the management of a duly qualified and registered chemist, that is not sufficient to relieve the employers from persecution. This is strange, because, according to the Act, in the case of the death of a chemist, any executor, or administrator, or trustee of his estate, may continue the business, provided they employ a duly qualified assistant. This is trade unionism with a vengeance. Is it not time that some agitation was instituted to obtain a repeal, or some amendment, of this obnoxious Act and the way it is administered? The thing will have to be done, and the sooner the better.

Trilby.—Visitors to the Haymarket Theatre on Monday night had a pleasant surprise in store for them in the shape of a souvenir, which was presented to every person present, from goda to pittites, to commemorate the one hundredth performance of *Trilby*. This took the form of a small portfolio containing seven beautiful photogravures, with the title, "A Souvenir of *Trilby*, by Paul M. Potter (founded on George du Maurier's novel), produced for the first time in London, at the Theatre Royal, Haymarket, on October 30, by Herbert Beerbohm Tree." Inside the cover is the original cast of *Trilby*, and then follow the photogravures. These are from negatives taken for the purpose by Mr. T. C. Turner (Turner & Drinkwater), of Hull, and that gentleman has every reason to be proud of his work. The pictures comprise a fine study of Mr. Tree as Svengali, which is followed by a most charming photograph of Miss Dorothea Baird as Trilby. The thorough manner in which this young lady looks Trilby and acts up to the character is quite wonderful. From the crown of her head to her pretty bare feet she is Trilby, and no one but Trilby. The other photogravures in this handsome souvenir are of Mr. Edward Maurice, as Taffy; Mr. Lionel Brough, as the Laird; Mr. Esmond, as Little Billee; Miss Fillippi, as Madame Vinard; and Miss Ivor and Mr. Allan, as the mother and uncle of Little Billee. The photogravures are excellently produced, presumably by Messrs. Virtue & Co., whose name is attached to the publication as printers. Should it become the custom to present audiences with such handsome books on the hundredth night of every play, such occasions will assume more importance than first nights, and quite a new opening will arise for the almost ubiquitous photographer.

Iris Diaphragms and Screen Work.—The convenience of the iris diaphragm, now so universally adapted to the better class of lenses, is beyond all question for ordinary purposes; but, when they are required for use in conjunction with the screen for half-tone work, Waterhouse stops, no doubt, offer greater facilities for the employment of openings of other than circular shape. In fact, as a diaphragm, the iris is useless except for circular apertures. But it requires the exercise of very little ingenuity to adapt lenses, so fitted, to the purpose in view with any form of diaphragm, though, perhaps, a little more trouble may be involved in changing the stops when necessary than would be the case if the usual Waterhouse slot were available. All that is necessary is to provide discs of blackened cardboard, or metal, with the desired shape of aperture, and made to fit either into the tube of the lens or its hood, the iris being kept permanently open or at its full aperture.

The best position—of course, theoretically—is in the tube of the lens, where the disc is readily kept in place, close to the iris, by means of a ring of rubber, similar to the adapters for instantaneous

shutters; but this will be found a decidedly inconvenient plan when the system of giving separate exposures with different sized stops is followed. In this case the simpler plan will be to place the diaphragm in the hood of the lens, as was formerly frequently done with portrait lenses; and, though this will necessitate a comparatively longer exposure than would be required if the same stop were fitted centrally, no other practical objection will be found, and the stops will be easily accessible when a change is necessary. With square and oblong-shaped apertures, we have not found any difference in the result produced, whether the stop is used in the body or on the hood of the lens, but we cannot speak to the effect of the more complicated shapes affected by some operators.

In using a diaphragm opening of other than circular shape, perfection of result, of course, depends as much upon the position of the stop in regard to the direction of the lines of the screen as upon anything else; for, clearly, an entirely different shape of dot would be produced when the diagonal of a square stop, or the longer dimension of an oblong one, lies in the same direction as the diagonals of the squares in the screen to what would be obtained if it were rotated through an angle of 45°. The correct position of the stop can readily be secured by carefully rotating the lens in its flange, or, better, if the stop be in the hood, by causing the latter to revolve, while the effect is watched on the focussing glass with a magnifier. If the body of the lens be revolved, it will be necessary to do the fine focussing after the position of the stop is secured.

Important Copyright Case.—Photographers often complain that, after having given permission, for a fee, for a reproduction of a picture in an illustrated paper, the block is used in other papers without permission or further fee being paid. In such cases the law will give redress, as it did one day last week. It appears that *Black and White*, the defendants, wrote to Mr. Reynolds-Stephens, the plaintiff, for permission to have a representation of his Academy picture, *In the Arms of Morpheus*, in their illustrated supplement, and in their hand-book for the Royal Academy and the New Gallery. This he consented to give for the fee of a guinea; but, instead of the picture appearing in the work for which the permission was given, it was, after a time, reproduced in an ordinary number of the paper. The plaintiff then took proceedings for damages for infringement of copyright, and an injunction to prevent any further infringement. It was stated at the trial that, had the picture been reproduced in the work for which consent had been given, it would have been an advantage to the plaintiff, but its appearing the following year in the ordinary newspaper would prejudice the chances of the picture being reproduced as a photogravure. A number of artists and print publishers were called to substantiate the plaintiff's case, and in the result the jury found that there had been an infringement, and awarded the plaintiff 100*l.* as damages.

In the forms issued by the Photographic Copyright Union there is a stipulation that the photograph for which the fee is paid is not to be used for any other purpose than that for which the permission is given and the fee paid. The above case, however, appears to show that this stipulation is really not necessary, although it makes it clearly understood that, if consent is given to reproduce a picture in one publication, it must not be used in another, even if it is not used in the one for which the permission was accorded. Photographers will, however, do well to make the stipulation, as it makes the matter quite clear to the purchaser of the right to reproduce that it is only for the purpose agreed for, and that alone.

RÖNTGEN'S DISCOVERY.

Now that the original paper by Professor Röntgen has reached us in England it is evident that the importance of his discovery cannot be at present gauged, even if we set aside altogether the somewhat curious but interesting experiments of photographing through wood and other substances. In the first place, it is obvious from Röntgen's paper that he has not rediscovered Lenard's cathodic rays, nor has he merely proved that the radiations at the ultra-violet end of the spectrum possess somewhat similar properties to those in the infra-red.

That they are not of the ultra-violet rays is surely proved by the fact that they cannot be refracted or reflected; that they are not cathodic rays is proved by their non-deflection by a magnet, and, according to Röntgen, start from that spot in the wall of the tube where the cathodic rays strike, not from the cathode itself.

A very important paper bearing upon the subject appears in the current issue of *Wiedemann's Annalen*, No. 1., 1896, p. 147, by Herr Jaumann, in which he points out that it is more than probable that the cathodic rays are longitudinal electric oscillations, as they are strongest in the axis of symmetry of the discharge space, and gradually decrease outward. Jaumann points out that the influence of the conducting wire upon cathodic rays proves that their period of vibration is of similar magnitude as the waves in the wires, that is, between 10–8 and 10–9 seconds; therefore, they are not ultra-violet rays, and further, if they were transverse without being ultra-violet, they would be ordinary light or Hertzian-waves. That the vibration of cathodic rays coincides with the direction of propagation, that is, that they are longitudinal, was proved by Lenard's experiments of their discharging influence when falling normally upon the surface of an electrode.

The essential difference between these X rays and ordinary rays will be at once seen if we recall the definition of ordinary light as vibrations of the ether particles in all directions *across* the line of propagation, or, in other words, the vibrations of ordinary light take place in every plane in succession perpendicular to the direction of the wave's motion.

That Röntgen's rays are not light in the ordinary sense of the word is obvious, and, further, his experiments prove that they are absolutely invisible to the eye even when the latter be placed close to their source.

An interesting experiment would be to try the effect of very thin plates of tourmaline on these rays, first with the optic axes of the crystals parallel, secondly with their axes at an angle of 45°, and then at right angles to see whether there is any connexion between polarised light and these new rays. E. J. WALL.

PROFESSOR RÖNTGEN'S DISCOVERY: ON A NEW KIND OF RAYS.*

[Nature.]

(1) A DISCHARGE from a large induction coil is passed through a Hittorf's vacuum tube, or through a well-exhausted Crookes' or Lenard's tube. The tube is surrounded by a fairly close-fitting shield of black paper; it is then possible to see, in a completely darkened room, that paper covered on one side with barium platino-cyanide lights up with brilliant fluorescence when brought into the neighbourhood of the tube, whether the painted side or the other be turned towards the tube. The fluorescence is still visible at two metres distance. It is easy to show that the origin of the fluorescence lies within the vacuum tube.

(2) It is seen, therefore, that some agent is capable of penetrating black cardboard which is quite opaque to ultra-violet light, sunlight, or arc-light. It is, therefore, of interest to investigate how far other bodies can be penetrated by the same agent. It is readily shown that all bodies possess this same transparency, but in very varying degrees. For example, paper is very transparent; the fluorescent screen will light up when placed behind a book of a thousand pages; printer's ink offers no marked resistance. Similarly the fluorescence shows behind two packs of cards; a single card does not visibly diminish the brilliancy of the light. So, again, a single thickness of tinfoil hardly casts a shadow on the screen; several have to be superposed to produce a marked effect. Thick blocks of wood are still transparent. Boards of pine two or three centimetres thick absorb only very little. A piece of sheet aluminium, 15 mm. thick, still allowed the X rays (as I will call the rays, for the sake of brevity) to pass, but greatly reduced the fluorescence. Glass plates of similar thickness behave similarly; lead glass is, however, much more opaque than glass free from lead. Ebonite several centimetres thick is transparent. If the hand be held before the fluorescent screen, the

* Translated by Arthur Stanton from the *Sitzungsberichte der Würzburger Physik-medic. Gesellschaft*, 1895.

shadow shows the bones darkly, with only faint outlines of the surrounding tissues.

Water and several other fluids are very transparent. Hydrogen is not markedly more permeable than air. Plates of copper, silver, lead, gold, and platinum also allow the rays to pass, but only when the metal is thin. Platinum ·2 mm. thick allows some rays to pass; silver and copper are more transparent. Lead 1·5 mm. thick is practically opaque. If a square rod of wood 20 mm. in the side be painted on one face with white lead, it casts little shadow when it is so turned that the painted face is parallel to the X rays, but a strong shadow if the rays have to pass through the painted side. The salts of the metals, either solid or in solution, behave generally as the metals themselves.

(3) The preceding experiments lead to the conclusion that the density of the bodies is the property whose variation mainly affects their permeability. At least no other property seems so marked in this connexion. But that the density alone does not determine the transparency is shown by an experiment wherein plates of similar thickness of Iceland spar, glass, aluminium, and quartz were employed as screens. Then the Iceland spar showed itself much less transparent than the other bodies, though of approximately the same density. I have not remarked any strong fluorescence of Iceland spar compared with glass (see below, No. 4).

(4) Increasing thickness increases the hindrance offered to the rays by all bodies. A picture has been impressed on a photographic plate of a number of superposed layers of tinfoil, like steps, presenting thus a regularly increasing thickness. This is to be submitted to photometric processes when a suitable instrument is available.

(5) Pieces of platinum, lead, zinc, and aluminium foil were so arranged as to produce the same weakening of the effect. The annexed table shows the relative thickness and density of the equivalent sheets of metal:—

	Thickness.	Relative thickness.	Density.
Platinum.....	·018 mm.	1	21·5
Lead.....	·050 ,, ...	3	11·3
Zinc.....	·100 ,, ...	6	7·1
Aluminium	3·500 ,, ...	200	2·6

From these values it is clear that in no case can we obtain the transparency of a body from the product of its density and thickness. The transparency increases much more rapidly than the product decreases.

(6) The fluorescence of barium platinocyanide is not the only noticeable action of the X rays. It is to be observed that other bodies exhibit fluorescence, *e.g.*, calcium sulphide, uranium glass, Iceland spar, rock salt, &c.

Of special interest in this connexion is the fact that photographic dry plates are sensitive to the X rays. It is thus possible to exhibit the phenomena so as to exclude the danger of error. I have thus confirmed many observations, originally made by eye observation with the fluorescent screen. Here the power of the X rays to pass through wood or cardboard becomes useful. The photographic plate can be exposed to the action without removal of the shutter of the dark slide or other protecting case, so that the experiment need not be conducted in darkness.

Manifestly, unexposed plates must not be left in their box near the vacuum tube.

It seems now questionable whether the impression on the plate is a direct effect of the X rays, or a secondary result induced by the fluorescence of the material of the plate. Films can receive the impression as well as ordinary dry plates.

I have not been able to show experimentally that the X rays give rise to any calorific effects. These, however, may be assumed, for the phenomena of fluorescence shows that the X rays are capable of transformation. It is also certain that all the X rays falling on a body do not leave it as such.

The retina of the eye is quite insensitive to these rays; the eye placed close to the apparatus sees nothing. It is clear from the experiments that this is not due to want of permeability on the part of the structures of the eye.

(7) After my experiments on the transparency of increasing thicknesses of different media, I proceeded to investigate whether the X rays could be deflected by a prism. Investigations with water and carbon bisulphide in mica prisms of 30° showed no deviation either on the photographic or the fluorescent plate. For comparison, light rays were allowed to fall on the prism as the apparatus was set up for the experiment. They were deviated 10 mm. and 20 mm. respectively in the case of the two prisms.

With prisms of ebonite and aluminium I have obtained images on the photographic plate which point to a possible deviation. It is, however, uncertain, and at most would point to a refractive index 1·05. No deviation can be observed by means of the fluorescent screen. Investigations with the heavier metals have not as yet led to any result, because of their small transparency and the consequent enfeebling of the transmitted rays.

On account of the importance of the question it is desirable to try in other ways whether the X rays are susceptible of refraction. Finely powdered bodies allow, in thick layers, but little of the incident light to pass through, in consequence of refraction and reflection. In the case of the X rays, however, such layers of powder are for equal masses of substance equally transparent with the coherent solid itself. Hence we cannot conclude any regular reflection or refraction of the X rays. The research was conducted by the aid of finely powdered rock salt, fine electrolytic silver powder, and zinc dust already many times employed in chemical work. In all these cases the result, whether by the fluorescent screen or the photographic method, indicated no difference in transparency between the powder and the coherent solid.

It is, hence, obvious that lenses cannot be looked upon as capable of concentrating the X rays; in effect, both an ebonite and a glass lens of large size proved to be without action. The shadow photograph of a round rod is darker in the middle than at the edge; the image of a cylinder filled with a body more transparent than its walls exhibits the middle brighter than the edge.

(8) The preceding experiments, and others which I pass over, point to the rays being incapable of regular reflection. It is, however, well to detail an observation which at first sight seemed to lead to an opposite conclusion.

I exposed a plate, protected by a black paper sheath, to the X rays, so that the glass side lay next to the vacuum tube. The sensitive film was partly covered with star-shaped pieces of platinum, lead, zinc, and aluminium. On the developed negative the star shaped impression showed dark under platinum, lead, and, more markedly, under zinc; the aluminium gave no image. It seems, therefore, that these three metals can reflect the X rays; as, however, another explanation is possible, I repeated the experiment, with this only difference, that a film of thin aluminium foil was interposed between the sensitive film and the metal stars. Such an aluminium plate is opaque to ultra-violet rays, but transparent to X rays. In the result the images appeared as before, this pointing still to the existence of reflection at metal surfaces.

If one considers this observation in connexion with others, namely, on the transparency of powders, and on the state of the surface not being effective in altering the passage of the X rays through a body, it leads to the probable conclusion that regular reflection does not exist, but that bodies behave to the X rays as turbid media to light.

Since I have obtained no evidence of refraction at the surface of different media, it seems probable that the X rays move with the same velocity in all bodies, and in a medium which penetrates everything, and in which the molecules of bodies are embedded. The molecules obstruct the X rays, the more effectively as the density of the body concerned is greater.

(9) It seemed possible that the geometrical arrangement of the molecules might affect the action of a body upon the X rays, so that, for example, Iceland spar might exhibit different phenomena according to the relation of the surface of the plate to the axis of the crystal. Experiments with quartz and Iceland spar on this point lead to a negative result.

(10) It is known that Lenard, in his investigations on kathode rays, has shown that they belong to the ether, and can pass through all bodies. Concerning the X rays the same may be said.

In his latest work Lenard has investigated the absorption coefficients of various bodies for the cathode rays, including air at atmospheric pressure, which gives 4·10, 3·40, 3·10 for 1 cm., according to the degree of exhaustion of the gas in discharge tube. To judge from the nature of the discharge, I have worked at about the same pressure, but occasionally at greater or smaller pressures. I find, using a Webber's photometer, that the intensity of the fluorescent light varies nearly as the inverse square of the distance between screen and discharge tube. This result is obtained from three very consistent sets of observations at distances of 100 and 200 mm. Hence air absorbs the X rays much less than the cathode rays. This result is in complete agreement with the previously described result, that the fluorescence of the screen can be still observed at 2 metres from the vacuum tube. In general, other bodies behave like air; they are more transparent for the X rays than for the cathode rays.

(11) A further distinction, and a noteworthy one, results from the action of a magnet. I have not succeeded in observing any deviation of the X rays even in very strong magnetic fields.

The deviation of cathode rays by the magnet is one of their peculiar

characteristics; it has been observed by Hertz and Lenard, that several kinds of cathode rays exist, which differ by their power of exciting phosphorescence, their susceptibility of absorption, and their deviation by the magnet; but a notable deviation has been observed in all cases which have yet been investigated, and I think that such deviation affords a characteristic not to be set aside lightly.

(12) As the result of many researches, it appears that the place of most brilliant phosphorescence of the walls of the discharge tube is the chief seat whence the X rays originate and spread in all directions; that is, the X rays proceed from the front where the cathode rays strike the glass. If one deviates the cathode rays within the tube by means of a magnet, it is seen that the X rays proceed from a new point, *i.e.*, again from the end of the cathode rays.

Also for this reason the X rays, which are not deflected by a magnet, cannot be regarded as cathode rays which have passed through the glass, for that passage cannot, according to Lenard, be the cause of the different deflection of the rays. Hence I conclude that the X rays are not identical with the cathode rays, but are produced from the cathode rays at the glass surface of the tube.

(13) The rays are generated not only in glass. I have obtained them in an apparatus closed by an aluminium plate 2 mm. thick. I purpose later to investigate the behaviour of other substances.

(14) The justification of the term "rays," applied to the phenomena, lies partly in the regular shadow pictures produced by the interposition of a more or less permeable body between the source and a photographic plate or fluorescence screen.

I have observed and photographed many such shadow pictures. Thus, I have an outline of part of a door covered with lead paint; the image was produced by placing the discharge tube on one side of the door, and the sensitive plate on the other. I have also a shadow of the bones of the hand, of a wire wound upon a bobbin, of a set of weights in a box, of a compass card and needle completely enclosed in a metal case, of a piece of metal where the X rays show the want of homogeneity and of other things.

For the rectilinear propagation of the rays, I have a pinhole photograph of the discharge apparatus covered with black paper. It is faint, but unmistakable.

(15) I have sought for interference effects of the X rays, but possibly, in consequence of their small intensity, without result.

(16) Researches to investigate whether electrostatic forces act on the X rays are begun, but not yet concluded.

(17) If one asks, What, then, are these X rays; since they are not cathode rays, one might suppose, from their power of exciting fluorescence and chemical action, them to be due to ultra-violet light? In opposition to this view, a weighty set of considerations presents itself. If X rays be indeed ultra-violet light, then that light must possess the following properties:—

(*a*) It is not refracted in passing from air into water, carbon bisulphide, aluminium, rock salt, glass, or zinc.

(*b*) It is incapable of regular reflection at the surfaces of the above bodies.

(*c*) It cannot be polarised by any ordinary polarising media.

(*d*) The absorption by various bodies must depend chiefly on their density.

That is to say, these ultra-violet rays must behave quite differently from the visible, infra-red, and hitherto known ultra-violet rays.

These things appear so unlikely that I have sought for another hypothesis.

A kind of relationship between the new rays and light rays appears to exist; at least the formation of shadows, fluorescence, and the production of chemical action point in this direction. Now, it has been known for a long time that, besides the transverse vibrations which account for the phenomena of light, it is possible that longitudinal vibrations should exist in the ether, and, according to the view of some physicists, must exist. It is granted that their existence has not yet been made clear, and their properties are not experimentally demonstrated. Should not the new rays be ascribed to longitudinal waves in the ether?

I must confess that I have in the course of this research made myself more and more familiar with this thought, and venture to put the opinion forward, while I am quite conscious that the hypothesis advanced still requires a more solid foundation. PROFESSOR W. C RÖNTGEN.

In regard to Professor Röntgen's discovery, Mr. A. A. C. Swinton writes in *Nature*:—

Working upon the lines indicated in the telegrams from Vienna recently published in the daily papers, I have with the assistance of Mr J. C. M. Stanton, repeated many of Professor Röntgen's experiments with entire success. According to one of our first experiments, an ordinary gelatinous bromide dry photographic plate was placed in an ordinary camera back. The wooden shutter of the back was kept closed, and upon it were placed miscellaneous articles, such as coins, pieces of wood, carbon, ebonite, vulcanised fibre, aluminium, &c., all being quite opaque to ordinary light. Above was supported a Crookes tube, which was excited for some minutes. On development, shadows of all the articles placed on the slide were clearly visible, some being more opaque than others. Further experiments were tried with thin plates of aluminium or of black vulcanised fibre interposed between the objects to be photographed and the sensitive surface, this thin plate being used in place of the wood of the camera back. In this manner sharper shadow pictures were obtained. While most thick metal sheets appear to be entirely opaque to the radiations, aluminium appears to be relatively transparent. Ebonite, vulcanised fibre, carbon, wood, cardboard, leather, and slate are all very transparent, while, on the other hand, glass is exceedingly opaque. Thin metal foils are moderately opaque, but not altogether so.

As tending to the view that the radiations are more akin to ultra-violet than to infra-red light, it may be mentioned that a solution of alum in water is distinctly more transparent to them than a solution of iodine in bisulphide of carbon.

So far as our own experiments go, it appears that, at any rate without very long exposures, a sufficiently active excitation of the Crookes tube is not obtained by direct connexion to an ordinary Rhumkorff induction coil, even of a large size. So-called high-frequency currents, however, appear to give good results, and our own experiments have been made with the tube excited by current obtained from the secondary circuit of a Tesla oil coil, through the primary of which were continually discharged twelve half-gallon Leyden jars, charged by an alternating current of about 20,000 volts' pressure, produced by a transformer with a spark gap across its high-pressure terminals.

For obtaining shadow photographs of inanimate objects, and for testing the relative transparency of different substances, the particular form of Crookes tube employed does not appear to greatly signify, though some forms are, we find, better than others. When, however, the human hand is to be photographed, and it is important to obtain sharp shadows of the bones, the particular form of tube used, and its position relative to the hand and sensitive plate, appear to be of great importance. So far, owing to the frequent destruction of the tubes, due to overheating of the terminals, we have not been able to ascertain exactly the best form and arrangement for this purpose, except that it appears desirable that the electrodes in the tube should consist of flat and not curved plates, and that these plates should be of small dimensions.

The accompanying photograph of a living human hand was exposed for twenty minutes through an aluminium sheet ·0075 in thickness, the Crookes tube, which was one of the kind containing some white phosphorescent material (probably sulphide of barium), being held vertically upside down, with its lowest point about two inches above the centre of the hand.

By substituting a thin sheet of black vulcanised fibre for the aluminium plate, we have since been able to reduce the exposure required to four minutes. Indeed, with the aluminium plate the twenty minutes' exposure appears to have been longer than was necessary. Further, having regard to the great opacity of glass, it seems probable that, where ordinary Crookes tubes are employed, a large proportion of the active radiations must be absorbed by the glass of the tube itself. If this is so, by the employment of a tube partly constructed of aluminium, as used by Lenard, the necessary length of exposure could be much reduced.

A. A. C. SWINTON.

ON A NEW METHOD OF PREPARING PLATES SENSITIVE TO THE ULTRA-VIOLET RAYS.*

[Communicated by Colonel J. Waterhouse, I.S.C.]

IT frequently happens that, for various experimental purposes, plates with a sensitive surface of pure silver bromide, or bromo-iodide, are required, and are not always easy to prepare. Some few years ago, Herr V. Schumann reported that he had found a means of preparing plates sensitive to the ultra-violet rays in regions hitherto quite unrecorded by photography. The full details of Herr Schumann's method of preparing these plates have now appeared in the Transactions of the Vienna Academy of Sciences, and present so many points of interest, and shew

* Translated from the *Sitzungsbericht der Kaiserlichen Akademie der Wissenschaften, Math-Naturwiss. Classe.* Band cii. Heft. 8, Wien, October, 1893, pp. 994-1024,

such thorough working out by Herr Schumann, that a translation of the paper seemed desirable. It was intended originally to be merely an abstract for my own use, but it was found very difficult to condense it without loss. The paper forms the sequel of two papers on the "Photography of the Rays of Shortest Wave-length," published in the same volume of the *Sitzungsberichte* (pages 415–475 and 625–694), which deal with the instruments and the necessary optical and electrical arrangements for taking these photographs of the region of the spectrum between w. l. 231·35 and 100·0 $\mu\mu$, and the many difficulties to be surmounted in doing so, especially in the case of the wave-lengths between 182 $\mu\mu$ and 100 $\mu\mu$, for which entirely special arrangements had to be adopted.—J. W.

Introduction.

In my previous papers (noted above), I have followed out the spectrum of electric discharges far beyond the hitherto known limits of the ultra-violet (185·2 $\mu\mu$), up to the neighbourhood of wave-length 100 $\mu\mu$. The observations were carried out by photographic methods as far as w. l. 182 $\mu\mu$ with gelatino-bromide plates, and thence to w. l. 100 $\mu\mu$, with a plate which I prepared specially for this purpose by a new method.

The rays beyond w. l. 182 $\mu\mu$ have remained quite inactive by any method of spectroscopic observation hitherto employed. They are only perceptible with the above-mentioned plates, with lenses and prisms of fluor spar, and with the spectroscopic apparatus in a vacuum.

The method of preparation of these plates is the result of a research not yet finished, which I only noticed briefly in the first part of the papers mentioned. It yields a coating for the plates of the desired fineness and sensitiveness, films which are more sensitive for the new rays than for the remaining part of the spectrum, and which, on this account, as I shall show later on, fulfil their purpose in two ways.

The plates are less satisfactory in other respects; they suffer in time from large and small defects in the surface, which can only be checked by proper exposure and by skilful application of definite precautionary measures for the development of the image. But, as soon as this precaution is put aside, numberless spots appear of different intensity and size which overrun the image and destroy its otherwise so remarkable sharpness. This is the direction in which my process requires improvement, and is, at the same time, the principal reason why I have not published it earlier. I certainly hope still to be able to overcome this defect, as a result of further researches, if more time is available to me for them, as my earlier observations lead me to believe.

Under such circumstances, it might have happened that the free publication of my process, which I had not intended until this improvement had been made, would have been indefinitely postponed; but this would not have agreed with the final object of my investigations, which was to make the spectroscopy of the new region of rays accessible as soon as possible.

The following circumstances have also influenced me:—The above-mentioned account of my researches on the shortest wave-lengths has, since its appearance met with such a friendly reception, that a more active interest in the investigation of the new region of rays seems to have already been secured. This is shown especially by the efforts that are being directed to the problem of extending our knowledge of the molecular theory by means of the spectrum. It may be remarked thereon, that the earlier researches in this direction, which first of all only aimed at the discovery of a regular connexion between the lines of an element and between the spectra of different elements have, up to the present time, given the most favourable results the nearer they have approached the hitherto known boundaries of the ultra-violet region. The shorter the wave-lengths of the region under observation were, so much the more markedly this regularity was disclosed. From this it may be expected that the new region of rays, with its incomparably shorter wave-lengths, will yield rich material for observation towards the completion, as well as for the verification of the results hitherto obtained; and so much the more that the investigation of a whole series of elements, which has hitherto been quite without result in the direction mentioned, is directed on this part of the spectrum alone. For observations of this kind the new plates, even before their improvement, should be a welcome help. It is this especially which has, in the first place, decided me to abandon my original intention and publish my process at once.

The following paper treats of my own personal labours. These include a series of researches which, in consequence of the not inconsiderable difficulties which were caused at first by the necessity for taking these pictures of the spectrum in a vacuum, have occasioned great expenditure of time and trouble. I have, therefore, contented myself with single trials of the respective experiments in cases where the verifying of the first results seemed to me superfluous. These results are naturally of inferior value, and it might, perhaps, have been better if I had passed them over in silence. My paper would then have been so incomplete, that their admission into it seemed to me to be the least of two evils. I shall, however, suitably note them in what follows, so that the possibly doubtful worth of one or the other of them may not influence the principal results of the investigation.

Spectrographic Preparatory Work.

The spectrum in the ultra-violet was already known as far as w. l. 185·2 $\mu\mu$. In 1890 I succeeded in discovering waves of shorter length as far as w. l. 182 $\mu\mu$ by means of photography. Beyond this the photographic plates failed; whether from want of sensitiveness or from the insufficient energy of the source of light, nothing further could be determined. The only possibility of obtaining an elucidation of this point lay in the measurement of the transparency to light of the different components of the sensitive coating of the plates. I used for this purpose gelatine dry plates containing gelatine and silver bromide.

Dry gelatine, as I was the first to show,* absorbs the ultra-violet rays very powerfully, and the more so in proportion to their refrangibility. A film only 0·00004 mm. thick is sufficient to weaken very sensibly rays of about w. l. 185·2 $\mu\mu$.

The coating of a gelatine dry plate is at least 500 times thicker. Consequently, waves of shorter length have not the power of penetrating the sensitive depths of such a film, or of reducing a sufficient quantity of silver haloid, to give a dense image. From this it may be concluded that the gelatine was not without a share in the loss of intensity of my pictures of the spectrum, and that a film of pure silver bromide might have given a better effect.

Pure silver bromide also stops the rays of light energetically; however, according to my photographs, it is rather more transparent for the wave-lengths 210 $\mu\mu$ to 185 $\mu\mu$, than for the rest of the spectrum. This slight difference was practically of little importance. Of much more importance was the extent of the extinction which might result photo-chemically or photo-thermically. The absorption spectrum failed to elucidate this point. The photographic behaviour of pure silver bromide could alone decide it.

With this object I coated a glass plate with a thin film of silver bromide, which had been precipitated with an excess of alkaline bromide, dried it, and with it took a photograph of the spectrum of the spark between two aluminium wires, using a quartz prism and lenses. The plate was developed like a gelatine dry plate, with pyrogallic acid, soda, and potassium bromide. The thickly fogged plate showed a continuous spectrum, which extended as far as wave-length 182 $\mu\mu$ in undiminished intensity, as a deep black band of action, bordered all round by a light edge. The continuity of this band was entirely owing to the spreading of all the lines together, an appearance which also occurs with gelatine plates of much higher sensitiveness.

From this negative I concluded that the modification of silver bromide in gelatine emulsion is not wanting in any way in sensitiveness for the most refrangible rays, nor these in photo-chemical energy, but rather that the want of sensitiveness of silver bromide in gelatine was a consequence of the weakening of the rays which these suffer on their passage to the silver bromide through the gelatine. Hence, it was to be expected that the sensitiveness of silver bromide plates could be increased by diminishing the quantity of gelatine, by substituting some more transparent binding medium for the gelatine, or, finally, by doing away with the binding material. This would only answer for the selected region of observation which ends with wave-length 182 $\mu\mu$. I therefore repeated these experiments for the more strongly refracted region lying near, taking care, however, to reduce the air space between the source of light and the plate, which I had already previously recognised as an important absorbent for short waves of light, to a layer of only a few millimetres thickness. In this way it was proved that a region rich in rays existed beyond 182 $\mu\mu$, and also that, for photographing, this pure silver bromide is sufficiently sensitive.

These photographs on pure silver bromide form the basis for the preparation of my plates sensitive to the ultra-violet rays, which is treated in the following section of this paper.

Preparation of Plates Sensitive to the Ultra-violet Rays.

This was tried in three ways—by coating with emulsion, by bathing in silver nitrate and potassium bromide solutions, and by coating with precipitated silver bromide.

A.—By Coating with Emulsion.

My endeavours to obtain an ultra-violet sensitive plate with emulsions

* See vol. cii. part 2, 1893, pp. 457–464.

of silver bromide have given no practical results. They are only mentioned for the sake of completeness.

I hoped, with a silver bromide emulsion containing two to three times as much silver bromide as usual, to obtain a coating poor in gelatine which would have allowed the rays to penetrate to a greater depth and given a more intense picture than is possible with ordinary silver bromide in gelatine. I obtained, however, the exact reverse of this. The silver bromide settled regularly at the bottom, even before the poured-out emulsion was set, so that the uppermost surface of the coating of the plate, which in this case is alone of service, consisted merely of gelatine. Plates of this kind were, from the reasons already explained, more insensitive for the most refrangible rays than ordinary dry plates.

An attempt to replace gelatine by agar-agar was still more unsuccessful: the coating of the plate separated, as soon as it was set, into particles, of varying sizes, an appearance which had already, some years before, prevented me from using agar-agar for emulsion purposes.

B.—By Immersion in Silver Nitrate and Potassium-bromide Solutions.

If a plate coated with gelatine is dipped in a solution of silver nitrate and then in a solution of potassium bromide, a coating of silver bromide is obtained, of which the outer surface is formed of silver bromide without any gelatine. When such a plate is exposed to light, the rays pass first through the silver bromide free from gelatine, and then through that which is enclosed in gelatine. From this film of silver bromide free of gelatine, I anticipated good results in photographing the smallest wave-lengths.

I coated a levelled glass plate with a three per cent. solution of gelatine, and, as soon as the coating was set, immersed it in a five per cent. solution of silver nitrate, let it drain, cleaned back and sides with blotting-paper, then immersed it again in the dark room in a three per cent. solution of potassium bromide, and washed it, the coated side being downwards and the water changed constantly. After drying, it was exposed to the spectrum of aluminium, and then developed with pyro-soda and potassium bromide.

The dried opaleacent unexposed plates were found to be unevenly transparent, and showed numerous irregular streaks. They fogged completely on development, and could only be kept clear by strongly diluting the developer. However, the lines were in all cases sharply shown, even when the plate fogged, and more intense than with a silver bromide emulsion. The photographic maximum of the plate exposed to aluminium light was about the two lines at 186·0 $\mu\mu$ and 185·2 $\mu\mu$. Both always developed much earlier than the other parts of the spectrum.

Gelatine emulsion plates behaved just the opposite, these lines always appearing last.

Gelatine bath plates consequently have an advantage over emulsion plates for photographing the most refrangible rays.

These photographs ended at wave-length 185·2 $\mu\mu$. The cause of this moderate range must be sought, however, not in the plate, but rather much more in the fact that its exposure was under the influence of an air space intervening in the path of the rays, and this, as before shown, is very slightly transparent to the ultra-violet rays.

The general sensitiveness of the gelatine bath plates was only moderate, and to have increased it, as was desirable, would have been difficult. I therefore contented myself with a single trial of this method, and, without exposing plates to the wave-lengths beyond wave-length 185·2 $\mu\mu$, passed on to the last of the methods given, which, in other respects also, promised better results.

C. By Coating with Precipitated Silver Bromide.

If solutions of silver nitrate and potassium bromide are mixed, a flocculent precipitate of silver bromide is obtained. Very dilute solutions behave otherwise. They give, with an excess of potassium bromide, an extremely fine precipitate, which first remains suspended, and only settles after standing for weeks.

The addition of a few drops of ammonia increases the deposit, and hastens the settling.

If a glass plate be laid at the bottom of the settling vessel, the silver bromide falls on it in a layer of even thickness, and, after the supernatant fluid has been syphoned off, dries in a short time to a dull yellowish coating, consisting of pure silver bromide, with a small mixture of the salts dissolved in the supernatant fluid (KNO_3 and KBr), which can be removed by washing. Such plates stand development, and also, to a certain extent, the fixing, without injury.

The above is a rough outline of the method I have used for years for preparing plates, which have enabled me to find the limits of the spectrum between wave-lengths 182 $\mu\mu$ and 100 $\mu\mu$. V. Schumann.

WINTER PHOTOGRAPHY.

[West London Photographic Society.]

My first duty this evening is to disclaim any pretensions whatever to the qualifications necessary for dealing in an instructive manner with the subject of Winter Photography.

As a matter of fact, not only was our Secretary good enough to allot me a vacant date in the syllabus, but he also kindly supplied me with the title for a paper, and instructions to proceed with the subject. Under the circumstances, the following remarks must not be taken as in any sense authoritative, but merely as a basis for discussion.

Winter photography is so general and comprehensive a term, that one might be expected to have something to say on every branch and phase of photographic work usual or possible during the winter season.

I have, however, found that to deal in a general way with the production by amateur workers of negatives and prints during the winter, and of wintry subjects, would be quite sufficient for one evening.

Obviously, then, the first point to be considered is, What preparations are necessary for outdoor work during the winter. One of the most important is to be sure of a supply of plates or films ready for immediate use, and it will frequently be found desirable to have the plate-holders already filled, so that not a minute may be lost indoors when the time for action comes. This is true even when applied to persons having plenty of leisure, and who are free to seize any opportunity that may present itself; much more so is it important for those whose time is principally occupied by business or professional duties. Perhaps it need hardly be stated that one reason for being constantly ready is, that many of the most beautiful effects of winter weather appear very suddenly in this country, and frequently last a few hours only. This is especially the case with hoar frost or rime, and not infrequently a fall of snow is quickly followed by genial sunshine, which causes the snow to fall from the trees, whilst that covering the ground loses its beautiful fleecy texture.

A precaution said to be especially necessary for securing the best rendering of snow scenes is to have the lens surfaces perfectly free from dust. Mr. F. M. Sutcliffe calls attention to this; he also urges the use of a single lens with a fixed stop in front, or, if using a doublet, that some precaution should be taken to shade the lens on the under side from the glare of a bright snow scene.

Personally, I had noticed that such subjects were more difficult to get clear and sharp than an ordinary landscape, and have been in the habit of using a much smaller stop than at other times. I am not, however, prepared to say that my practice is as effective as that advised by Mr. Sutcliffe—probably it is not.

In working among masses of ice such as may at times be found on the shores of a tidal river, it will be found an advantage to have the spikes of the tripod sharpened up to a fine point, so as to get a firm hold on the surface of ice.

On such occasions I have found as a makeshift a piece of stout string useful for fastening the tripod legs to one another at about mid-length, to prevent them spreading on the slippery surface.

Some uncertainty has, no doubt, been felt as to the best plate or film for winter work, and as to whether any particular plate is better than another. On this point I prefer not to ask you to rely on my own experience entirely, but will add the views of such authorities as I found handy when preparing these remarks.

Of the utility of backing all plates there can be no question, as, without doubt, some of the most beautiful effects are most trying, owing to extreme contrasts; neither can there be any excuse for not doing so since the advent of specially prepared backing paper at a very low price. My own recent practice has been to use films only, which do not appear to need backing.

As to the rapidity of plate, I have always used a medium or rapid plate, and I find that the practice is in agreement with the results of experiments made for the purpose of ascertaining what class of plates was least affected by low temperatures. It will be evident that a thickly coated plate or film is very desirable for the proper rendering of great extremes of light and shade.

This brings us to the consideration of a point of some interest from its scientific aspect, but which, I venture to think, is not of so much practical importance as some would have us believe. I refer to the influence of temperature on the sensitiveness of the gelatino-bromide plate. My own opinion—which, at best, must be considered as merely the result of observations in practical working—is that temperature, in this country at any rate, need not be seriously taken into account.

However, we will consider what has been proved by scientific research, and leave its practical applications to the judgment of individual workers. Professor Dewar was an early experimenter with photographic plates at temperatures far below anything known to exist outside of a chemical laboratory, and which he describes, in a lecture at the Royal Society, as "a temperature by the side of which the arctic regions would appear like the plains of India." He also said that "he had been puzzled to find that, whereas other chemical action ceased, photographic action, although considerably diminished, still went on. The impression on a chilled film was less by about eighty per cent. than that left on a film at ordinary temperature, but there it was."

I think you will all agree that a loss of eighty per cent. of sensitiveness at such a temperature as −180° C., or 292° below zero Fahr., conveys no idea of practical value to those working in ordinary winter weather.

Another experimenter, Dr. J. Joly found that the effect of difference of temperature was much more marked on an isochromatic plate than upon a plain silver bromide plate. His experiments also showed that practically the isochromatic plate was reduced by cold to the limits of sensitiveness of the undyed plate, and that, under conditions of extreme cold, isochromatic plates possess but little advantage in colour correctness over ordinary plates.

G. F. Blackmore.

THE SOLAR CORONA PHOTOGRAPHED IN DAYLIGHT.

Mr. D. E. Packer, of the Astrophysical station, South Birmingham, writes to the *English Mechanic*:—

"From innumerable experiments made during the last six months, it has been found that metallic plates, foils, and films are relatively transparent to solar radiance of high refrangibility, and that photographic plates screened by such media during exposure to direct sunlight are affected in proportion to the thinness and electrical conductivity of the interposed screen.

"This interesting discovery has been successfully employed in photographing the solar corona. The results obtained are so remarkable, and the recorded coronal changes so great and rapid, that great caution had to be exercised till a sufficient mass of confirmatory evidence could be obtained to justify this announcement. The photographs secured range from 1895, July 3 to December 15, on which latter date Comet Perrine is also shown very close to its calculated place.

"The earlier photographs were taken with cameras of 4 inch and 1 inch aperture; the metallic screens employed were tin and lead foil and sheet copper. Prominent equatorial extensions over the region of active sunspot groups are the chief features of these pictures.

"By far the most remarkable coronal photographs were obtained without any camera lens at all, merely a small, neat pinhole aperture being used. These show, in some instances, an astonishing wealth of detail, more sharply defined, and of greater extent, and agreeing, in the more prominent features, with ordinary camera exposures taken at the same time. This agreement was invariably found to exist—a proof of the objective reality of the phenomena.

"It is well known that the absorption by glass lenses of the rays of higher refrangibility increases rapidly beyond the H and K lines of the spectrum, until opacity is reached. Lenses of quartz or rock crystal are known to possess a far greater transparency to these ultra-violet rays; but a small, clear aperture (pinhole) is obviously the best of all, as it transmits rays of every degree of refrangibility entirely unaffected; hence the superiority of photographs taken by such means over ordinary camera exposures.

"A preliminary discussion of the photographs show clearly the following characteristics:—

"1. A very close and intimate connexion with contemporary sunspots and sunspot groups. Active spot groups, especially when near the limb, are indicated by enormous coronal radiations over the particular region of activity, the coronal changes synchronising with the sunspot changes. It may be regarded as an axiom that 'every sunspot has its coronal ray,' as every prominent radiation may be easily assigned to its particular spot to which it invariably points. This remarkable association was unexpected at first; hence I neglected to note the spot configurations on the sun's disc, and several puzzling appearances on several of the more important photographs gave rise to doubts, which have been in great part dissipated by reference to Miss E. Brown's important paper on 'The Sunspots of the Last Year' (1894-5), *Journal B.A.A.*, vol. vi., p. 15, which has helped to explain several of the appearances. It has been found necessary to pay particular attention to the sunspot appearances on every occasion when photographs have been taken, which has been rewarded by repeated confirmation of this newly discovered association.

"2. That the well-known typical spot-minimum and spot-maximum coronal phases alternate pretty rapidly, apparently synchronising with observed short-period phases of spot activity and quiescence.

"3. That many of the most prominent radiations exhibit a decided helical structure, two or three convolutions, in some instances, being distinctly traceable—a surprising and unexpected feature.

"4. The great photographic strength of the coronal rays as compared with the feeble image of the solar disc, which has given rise to the inference that the coronal radiations are the chief source of the electrical energy from our central orb."

The Inquirer.

*** *In this column we shall, from time to time, print questions that may be addressed to individual contributors to our pages, or such as are sent to us with the view of eliciting information from a variety of sources. We invite the co-operation of our readers in rendering this feature of the* Journal *useful and instructive.*

Acetylene Gas Generator (To Mr. Thompson).—Messrs. F. S. Thorn & Co. write: "Seeing Mr. Thompson's inquiry, *re* Acetylene Gas Generator, of the 17th inst., may we state that we are manufacturing a simple generator suitable for the lantern, or enlarging purposes. It is quite safe and automatic in action, and gives from two to three hours light with one charge of calcium carbide."

Collodion Emulsion (To Mr. E. Banks).—J. Hampton says: "I have made up five ounces of collodion-emulsion (see The British Journal Photographic Almanac). Mr. Banks says add bichromate, after add cadmium bromide till the red colour is gone. I added a little at a time to the cadmium till I have used about one ounce, and I find that after the emulsion stands about one hour, there forms at the top of the emulsion a layer the colour of a deep buff. I should like you to kindly tell me about how much bromide to add to get the emulsion right. I may add that I can get a negative as it is now. The lower part of the emulsion is the colour of a warm grey, after standing."

Acetylene.—E. W. B. writes as follows: "We have heard a great deal about the wonders that are to be expected from the new acetylene gas, but more especially its cheapness as compared with ordinary coal gas; but on reading Mr. Edwin Banks's very interesting article in the last number of The Lantern Record, I find it difficult to reconcile his statements with the expectations held out by others. The price of the calcium carbide is variously quoted at from about 2*s.* 6*d.* a pound to 6*d.*, or, as Mr. Banks says, at 2¾*d.* per pound by the ton. Taking even this estimate as being the correct one when the stuff is properly on the market, and allowing that the new gas gives much more light, volume for volume, than the old, I cannot even then see how five cubic feet—the quantity stated by Mr. Banks to be obtainable from one pound of the carbide—costing 2¾*d.* can compete with coal gas at, say, 2*s.* 6*d.* per thousand. Is there not some mistake somewhere?"—We are not aware what volume of the gas has been obtained practically from a given weight of the carbide; but, supposing the latter to be chemically pure, which, of course, the commercial article is not, and calculating from its chemical composition and the specific gravity of the gas, the product should be nearer five hundred than five cubic feet per pound. Perhaps some of our chemical readers may have had practical experience in this direction, and be able to throw more light on the question.

NON-FUGITIVE DYES.—L. M. FRAZER writes: "Regarding *Dyes and Photographic Mordants* in December 27 number, could you inform me of three dyes, blue, red, and yellow, which would not fade in the sunlight? I have tried Judson's and find a day in sunlight fades them badly. If three pure primary tints could be had, others could be made from them."

COMMERCIAL PRINTING.—PHOTOGRAPHER asks the following question: "What is about the average number of frames a photographic printer (and a boy to assist in changing, &c.) would be required to keep going, including fitting up, &c., the greater part of which would be vignetted? Also about the number of prints they should get off between nine o'clock in the morning and three in the afternoon, allowing an hour, each of them, for dinner, taking a bright day as an example?"—Possibly some reader, who has had more experience with commercial printing than we have, will give his ideas.

RATIONAL DEVELOPMENT.—Writing *apropos* of the development query in this column a fortnight ago, J. C. says: "Such formulæ as the one referred to, in which one ounce of pyro is to be dissolved in eighty ounces of water, are absolutely ridiculous for practical purposes, unless in establishments where that quantity of pyro is used in a few hours, and even then it might be more conveniently employed in a more concentrated condition. The quantities of sulphite and of sulphuric acid are totally inadequate to preserve the pyro in that dilute state, though sufficient of the volume of solution be reduced to one-fourth or one-fifth; but then the only convenience of such a formula disappears, namely, the simple mixture of equal parts for use. The disadvantage of the system lies in the impossibility of modifying the developer, except within very narrow bounds, to meet errors in exposure, as the only power the operator possesses is in the direction of varying the proportions of pyro and alkali, whereas with the more rational 'ten per cent. solutions' the mixture can be strengthened, diluted, and varied in any desired degree with the greatest accuracy. Again, when the bromide is in combination with either the pyro or the alkali, the operator has certainly not full control of his developer say, for instance, if he wishes to add more alkali in a case of under-exposure. In adding the alkali, he must perforce also add a certain quantity of bromide which may be sufficient to counteract any benefit otherwise accruing from the addition of alkali. Can you not, sir, once more exert your influence in the direction of having ten per cent. solutions recognised as the standard developing solutions by all the makers of plates?"—In reply, we can only say that it was, we believe, in these columns that "ten per cent. solutions" were first recommended some years ago, but that was at a period when pyro-ammonia was almost solely used. Now, with numerous other reducing agents and other alkalies, it would not be so easy to apply universally the same system; but we do think that some nearer approach could be made to uniformity in the expression of formulæ if makers would only "put their heads together."

Our Editorial Table.

LAST week, when noticing *The Grammar of Photo-engraving*, we omitted to say that the author is Mr. H. D. Farquhar, and that the publishers are Messrs. Dawbarn & Ward, Farringdon-avenue, E.C.

News and Notes.

PHOTOGRAPHIC CLUB.—The next weekly meeting of the Club will be held in the Club-room at Anderton's Hotel, Fleet-street, E.C., at eight o'clock on Wednesday evening, February 5. There will be an exhibition of American and foreign photographs, arranged by Mr. Walter D. Welford. Visitors are always welcomed by the members.

REMARKABLE CHANGE IN THE STRUCTURE OF GLASS BY HEATING.—Among the thin-sided tubes of soda-glass produced for chemical purposes, there are occasionally some which, on heating, undergo a strange modification of structure. At the temperature of boiling water the upper layer displays, both within and without, a vast number of fine cracks running in all directions. These cracks do not penetrate deeply into the glass, so, that when the scales are rubbed off, the body of the tube has not lost much in thickness.—E. PRIWOZNIK in *Zeitschrift für Anorganische Chemie.*

DURHAM CITY CAMERA CLUB.—The following gentlemen have kindly consented to act as Judges at the above Club's Exhibition: Mr. J. P. Gibson, Hexham; Mr. W. Parry, photographer, South Shields; and Mr. Frank Thompson, Head Master, School of Art, Durham. The Hon. Secretary desires us to state that all exhibits will be repacked and dispatched the day following the close of the Exhibition.

PROFESSOR PAUL CZERMARK, of Graz, has succeeded in photographing a living skull without its fleshly integument by means of Professor Röntgen's X rays. An editor of the *Grazer Tagblat*, eager to observe the process, offered to have his skull "taken;" but, when he saw the result, he absolutely refused to have the picture reproduced, or even shown to any one, except men of science. He is reported not to have slept a wink since he saw his own "death's head."

THE PRODUCTION OF STEREOSCOPIC EFFECTS.—Mr. W. Mathews writes: Please note that your printer has fallen into the error of stating the year "1895"—(last year)—as the date of that communication of mine to your JOURNAL which dealt with the "Initial Stage" of "Composite Portraiture." It should have been, of course, 1885, which is over ten years ago. My earlier exemplars preceded the "Galton Composites" by more than two years. One of them, framed, still records itself as having been produced in the year "1878."

COMBUSTION OF ACETYLENE.—Mixtures of acetylene with air containing a proportion of the gas below 7·74 per cent. burn, yielding carbonic acid and water, with a yellowish flame feebly luminous. For proportions of acetylene between 7·74 and 17·37 per cent, the flame is of a pale blue, with a slight yellowish halo. The products of the combustion are carbon dioxide, carbon monoxide, watery vapour, and hydrogen. If acetylene is burnt with an equal volume of oxygen, it gives a temperature of 4000°; consequently superior by 1000° to the mixture of oxygen and hydrogen. The products of combustion consist exclusively of carbon monoxide and hydrogen, both reductive gases. This double property will render the use of acetylene in laboratories very valuable.—H. LE CHATELIER in *Comptes Rendus.*

THE LATE H. J. NEWTON.—*Apropos* of this well-known New York amateur photographer, who died recently, the *Scientific American* writes: "He began the practice of photography soon after the introduction of the Daguerreotype, and by research and experiments was able to suggest and introduce several useful improvements in photographic manipulation. Having acquired the art of drawing and painting, and noticing the usefulness and adaptability of photography for obtaining details which it would be difficult to remember, he became infatuated with the new discovery and devoted himself earnestly to its improvement and perfection. He had his laboratory and skylight arranged on the top floor of his residence, where he pursued his experiments. He recommended the use of nitrate of ammonia in the silver bath for the sensitising of albumen paper, by which the need of preliminary fuming with ammonia is avoided. About 1876-7 he improved the collodio-bromide emulsion process, and prepared an emulsion by which dry plates as sensitive as those by the wet-plate process could be made and used at any convenient time. He further suggested the use of the fixed alkalies such as carbonate of soda in developers in place of ammonia, and later, with the introduction of the gelatine dry-plate process, advised the use of yellow prussiate of potash in the pyro developer, which gave the latter greater vigour and produced more brilliant negatives. He also recommended the single solution iodide of mercury intensification method for gelatine plates. Since the introduction of the coal-tar developers he suggested certain modifications in their use for the development of prints on bromide paper, advising particularly the addition of, to a metol and hydroquinone developer, barium hydrate as yielding velvety black prints. He was identified with several photographic societies, and had been President of the photographic section of the American Institution for many years; also, at one time, he was Vice-President of the Society of Amateur Photographers, of New York."

PROFESSOR HERKOMER'S "NEW ART."—On Tuesday, at the Fine Art Society's Rooms, in describing his invention, Professor Herkomer stated that on the polished surface of a copper plate, coated with silver, the artist painted his picture with a thick black pigment resembling printer's ink. In the production of this painting he used brushes, leathers, bits of wood, his finger-tip—in fact, anything that would enable him to get the desired effect. So far, it was a positive process, requiring therefore no reversion of the subject on the plate—an inestimable boon to the artist. An examination of the painted plate showed that the ink was on the surface in different degrees of thickness, and in this variety of depth in the ink lay the first vital point of the invention. The artist, however, need in no way think of this necessary condition; it came without conscious effort in the making of his tones and gradations. This painted surface, with the ink still wet or soft, was then dusted over with a particular granulated powder, until neither the black paint nor the brighter parts of the plate were visible. A knock on the back of the plate, and the subsequent use of a soft camel's-hair brush removed the superfluous powder. As the powder contained both coarse and fine particles, it stuck to the various parts in a most discriminative way, the coarser grain adhering to the parts where the ink happened to be thick, and the finer where the ink was less, such as in the grey or light tones. Thus there was now secured a painted picture, dusted with a powder which granulated the painted touches in perfect proportion to their depth of tone, without, however, in any way altering their autographic character, but it caused the paint to cover new technical ground, and was the first stepping stone towards the conversion of the painted surface into a printing surface. In the third stage there was taken of this granulated surface a "metallic mould," or, in other words, an electrotype. Such was the conductibility of this surface that (all things being right) in ten minutes a blush of copper would spread over the whole surface when subjected to the electric bath. This settled in the most minute crevices and interstices. The plate was left in the bath until the copper deposit was as thick as an ordinary printing plate. By filing the edges the deposited plate was separated from the original painted plate, and in the former was obtained an exact negative or mould of the painted and powdered surface from which, by the ordinary methods of copper-plate printing, a perfect reproduction of the original painting was obtained.

DEATH OF MR. JOHN ADAMSON, JUN.—We regret to have to record the death of Mr. John Adamson, jun., Rothesay photographer, which took place recently after a severe illness of several months, at his residence, Firwood, at the comparatively early age of 45. Mr. Adamson for several years past has been the sole partner in the firm of John Adamson & Son, photographers, his father, its founder, having retired after having been in business for about forty years. Mr. Adamson, sen., previous to coming to Rothesay, had a studio in Glasgow, and was considered one of the best photographers by the older methods of the art. Mr. Adamson, jun., had the full advantage of being trained under his father from his earliest youth, besides obtaining experience in Glasgow, where, for a number of years, he conducted a Glasgow branch of the Rothesay business. For several years past the deceased devoted much of his attention to marine photography, and particularly to taking views of ships and yachts under sail, in which branch of the business he was almost unrivalled. His views of the fastest steamships and yachts taken at full speed were exhibited in all the great shipping ports of the kingdom and elicited the warmest admiration.

SOLIDIFIED GELATINE.—Gelatine possesses the curious property of becoming insolnble in contact with formic aldehyde, and, at the same time, of preserving perfect transparency. Gelatine rendered insoluble, or "petrified," to use a more appropriate term, resists water, acids, and alkalies. It resembles celluloid, but has the great advantage over the latter of not being inflammable. We have here, then, a new product very easy to obtain, possessing interesting properties, and destined to play an important *rôle* in the industries. The gelatine used is the ordinary article found in commerce. The formic aldehyde is what is commonly called "formol," "formaline," and "tannaline." The commercial product is a forty per cent. solution of formic aldehyde in water. It is a colourless, sirupy liquid of a pungent odour. The vapour is not inflammable, and it is a powerful antiseptic. In order to obtain moulds of statuettes, &c, we take, for example, two pounds of good white gelatine, and steep it in a quart of water for a night. The next day the whole is melted over a water bath. For delicate mouldings, the solution is diluted with a little water. The mould, which may be made of plaster, clay, or metal, having been prepared, the formic aldehyde is poured into the melted and slightly cooled gelatine. The whole is well stirred with a wooden spatula in order to obtain a homogeneous mixture. The latter is then poured into the mould and allowed to cool. After the object is taken from the mould it is finished by immersing it for a few instants in a concentrated solution of formic aldehyde, or, if it is too large for immersion in the solution, its surface is painted therewith. Unfortunately, objects obtained with the gelatine alone are transparent and resemble glass. By previously adding to the gelatine some finely sifted zinc white mixed with a little water and alcohol, and in operating in the same way, beautiful imitations of white marble may be obtained. By mixing the oxide of zinc with appropriate colours, objects of all shades may be obtained, and, by properly arranging the colours, veins, striæ, spots, &c., may likewise be produced. The solidified gelatine may be used for imitating mother-of-pearl, tortoiseshell, amber, coral, &c., and for the manufacture of toys and artificial flowers.

Patent News.

THE following applications for Patents were made between January 13 and 25, 1896:—

PANORAMIC CAMERAS.—No. 869. "Improvements in Photographic Cameras for taking Panoramic Views." L. JEFFERY.

HALATION PREVENTIVES.—No. 871. "Certain new and useful Improvements in Preventing Halation in Photographic Dry Plates." W. HAYDON.

PHOTOGRAPH-HOLDERS.—No. 905. "Improvements in Appliances for Holding Cards, Photographs, and the like, during Sale or Exhibition." L. MYERS.

PRINT-WASHER.—No. 913. "A New or Improved device for Washing Photographic Prints." W. KERR.

ARTIFICIAL LIGHT.—No. 972. "Improvements in Artificial Light Apparatus applicable for Photographic Purposes." J. PARKINSON.

EXHIBITING TRANSPARENCIES.—No. 1088. "Automatic Clockwork Motor for Exhibiting Photographs, Transparencies, or Advertisements, either by Daylight or Artificial Light." T. ILLINGWORTH.

LANTERNS.—No. 1142. "An Improvement in Optical Lanterns." B. ACRES.

TRIPODS.—No. 1307. "Improvements in Mounting photographic Cameras on their Tripods or Supports." J. H. FAY.

PRINT WASHER.—No. 1339. "An Improved Washing Apparatus for Photographic Prints." W. M. SIMPSON.

CHANGING BOX.—No. 1381. "Improvements in or relating to Change Boxes for Photographic Cameras." F. S. LITCHFIELD.

BURNISHER.—No. 1391. "Improvements in Machines for Calendering or Burnishing Photographic Prints." W. PRATT.

CHANGING BOX.—No. 1423. "Apparatus for Changing Sensitive Photographic Plates and Films (without consequent exposure to light) before and after Exposure in the Camera." J. BIDGOOD.

PHOTOGRAPH-HOLDERS.—No. 1481. "Improvements in or connected with Stands, Holders, Clips, or Devices for holding or supporting Photographs, Pictures, and other Documents." T. GAZE.

GELATINISED PAPER.—No. 1556. "Improvements in the Manufacture of Gelatinised Paper or other Fabric suitable for the Reproduction by Printing with Fatty Inks of Writings, Drawings, and the like." C. RAYMOND.

SPOOLS.—No. 1573. "An Improved Roll or Spool upon which Flexible Photographic Films are wound." J. B. B. WELLINGTON.

PHOTOGRAPH FRAMES.—No. 1650. "Improvements in Strut-backs for Picture and other Frames." L. A. MARION, H. GUIBOUT, G. BISHOP, F. BISHOP, and J. P. KIRK.

ELECTRIC LAMP.—No. 1793. "The Inglis Electrical Photographic Lamp for Studio Purposes." J. M. INGLIS.

PRINT-WASHER.—No. 1822. "Improvements in or relating to Photographic or other Prints." T. J. FOSTER.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

February.	Name of Society.	Subject.
3.....	Camera Club	Smoking Concert.
3.....	Richmond	*Our Tour in Norway.* F. A. Bridge and A. Bridgman.
3.....	South London	*The Chemistry of Every-day Photography.* W. H. Dawson.
3.....	Walthamstow	*Paris.* A. P. Wire.
4.....	Birmingham Photo. Society ...	Exhibition of Photographs of the Transvaal and South Africa. Sir J. Benjamin Stone, M.P.
4.....	Brixton and Clapham	Lantern Evening.
4.....	Gospel Oak	*Hints on Enlarging.* J. Bishop.
4.....	Hackney	*Amateur Photography in America.* Mrs. Snowden Ward.
4.....	Putney	*Uranium Toning and Uranium Intensification as applied to Picture-making and Photo Plastics.* Albert Hill.
5.....	Borough Polytechnic	*Gleanings Here and There.* E. Dockree.
5.....	Croydon Camera Club	Special Council Meeting.
5.....	Photographic Club	Exhibition of American and Foreign Photographs.
5.....	Southport	R. W. Thomas & Co.'s Slides Illustrative of the Special Properties of their Anti-halation Plates
6.....	Bradford	Lecture and Demonstration. N. Lubochez.
6.....	Camera Club	*Lincoln Cathedral.* Mr. Evans.
6.....	Ealing	Lantern Evening.
6.....	Liverpool Amateur	Lantern in Use.
7.....	Birkenhead Photo. Asso.	*Wensleydale.* The Secretary.
7.....	Croydon Microscopical	Conversational Meeting.
7.....	Moseley and District	*Some Points in Connexion with Picture-making.* Hubert Coop.
7.....	West London	Annual Dinner.

ROYAL PHOTOGRAPHIC SOCIETY.

JANUARY 28,—Technical Meeting,—Mr. E. Cecil Hertslet in the chair.

Scrutineers were elected for the forthcoming election of Council, &c.

PROFESSOR RÖNTGEN'S DISCOVERY.

Mr. J. W. GIFFORD sent specimens of his latest results in photographing with the invisible rays from a Crookes tube, including a representation of the skeleton of a human foot, taken by means of a spherical radiant tube, an Apps intensity coil, and a hand dynamo, the time of exposure being half an hour. This photograph showed an osseous protuberance of the metatarsus, occasioning distortion of the great toe. There were also exhibited prints from negatives by Mr. Gifford, one being a pinhole picture of the tube itself, and another showing some metal discs, which had been shielded by a cardboard box and a thick porcelain dish, there being strong evidence that sparking, or something similar, had taken place between two of the discs.

Mr. T. E. FRESHWATER showed lantern slides from Mr. Swinton's negatives. One represented a razor photographed while in a cardboard razor case, and showing only the blade and metal cap at the end of the handle; others showed the contents of a leather purse, taken through a sheet of aluminium of considerable thickness; a corkscrew, and other metallic objects, which had been enclosed in a calico pocket; an ordinary blacklead pencil, showing the cap protecting the point, and also the strip of blacklead, but not the wooden casing; and the skeleton of a frog. [These slides were referred to in our last issue, page 59.]

Mr. CROFTON asked whether any attempt had been made to ascertain whether these rays could be refracted, and suggested that, by means of a lens of ebonite, real photographs might be obtained instead of shadowgraphs.

Mr. W. E. DEBENHAM suggested the use of a mirror, as in the early Daguerreotype days.

Mr. T. BOLAS, referring to the spark mentioned by the Assistant Secretary in connexion with one of Mr. Gifford's photographs, thought it could hardly have been a spark in the usual acceptation of the term, but rather some kind of Hertzian discharge.

The ASSISTANT SECRETARY was inclined to think it was an actual discharge.

Mr. BOLAS said the point was of special interest, because, if the radiations from a Cookes tube would cause a sparking between two metal objects, that was one fact which brought them nearer the category of Hertzian oscillations and ordinary light.

Mr. E. J. WALL said Professor Röntgen had tried lenses of pitch and ebonite, and found it impossible to refract the rays.

Mr. BOLAS remarked that at the last meeting of the Society Mr. Gifford had showed results which clearly indicated that the rays were refrangible by ebonite.

The ASSISTANT SECRETARY differed from Mr. Wall, and said Professor Röntgen had quoted experiments showing that the rays could be refracted.

Mr. J. H. AGAR BAUGH read a paper describing

DR. RUDOLPH'S METHOD OF LENS-TESTING,

and showed some of Dr. Rudolph's results of tests of Zeiss anastigmats and

other lenses. The operations described had special reference to means of ascertaining the quality of definition from the middle to the edge of the field, the distribution of depth of focus on the ground glass, and the angle of the sharp image with different diaphragms, and the only method which Dr. Rudolph thought satisfactory for showing these properties was to photograph a suitable test object. The test object used consisted of a series of rods or vanes mounted spirally one behind the other, and to which printed cards were affixed, the exact construction being shown by Mr. Baugh by means of lantern slides. Dr. Rudolph had pointed out that his method possessed a very important property, in that the results showed in themselves whether all the adjustments precedent to the test had been accurately made.

Mr. DEBENHAM said that spirally mounted objects, used singly, were a very old device for testing lenses, but the employment of a number of such objects, covering nearly the whole of the field, as in Dr. Rudolph's method, was very convenient and useful, and enabled one to draw out a chart of the character of the lens for flatness of field, definition, &c.

The HON. SECRETARY believed the chief advantage of the process was that by it the depth of definition all over the field could be measured, and, at the same time, an exact estimation of the curvature of field could be made, which was not possible with a flat test object.

A vote of thanks having been passed to Mr. Baugh,

Mr. FRED ILES exhibited a series of slides which, he said, were the first results of various attempts he had made in producing

STEREO-MICROGRAPHS

with colour-tone effects. It might be said, he admitted, that he was endeavouring to add a meretricious character to a subject which should be dealt with in a purely scientific and analytical manner, but his object had been to render photographic images of microscopic objects in such a form that they should be attractive, interesting, and instructive to a non-scientific audience, and to popularise a somewhat neglected branch of photography. He had endeavoured to produce, as nearly as possible, a solid or steroscopic image of medical and botanical sections, diatoms, insect parts, and other microscopic objects, and to render them as nearly as possible in their natural colours, or in contrasting colours to the background, so as to show to the best advantage. By means of a special method of illumination he had succeeded in producing slides which gave the appearance of solidity and rotundity to the specimens photographed, fat cells from the omentum of a cat, for instance, showing as solid globules, and the enveloping tissue being readily distinguished from the cells themselves; a number of slides were atso exhibited, in which those produced by the modified treatment showed great superiority to the ordinary photo-micrographs. Mr. Iles then passed through the lantern a series of stereo-micrographs, the colour of which had been changed by chemically toning the image, the background not being affected, and much admiration was expressed by the audience for the beautiful results which had been obtained.

A brief discussion followed, in the course of which two or three members sought to elicit from Mr. Iles some details of his methods, both of photographing the objects and of toning the slides, but he declined to be "drawn," stating that his apparatus had been patented, and would eventually be placed on the market. The proceedings concluded with a hearty vote of thanks to Mr. Iles.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

JANUARY 23,—Mr. J. S. Teape in the chair.

RÖNTGEN'S DISCOVERY.

Mr. E. J. WALL said that a full translation of Röntgen's original paper would appear this week in one of the English papers. Although it has been assumed that these rays are cathodic rays, Prof. Röntgen says that they are not, and prefers to style them × rays. Referring to statements connecting them with the Hertzian rays, Mr. Wall said they were totally different, as they cannot be refracted, at least at present.

Mr. T. E. FRESHWATER, after quoting some remarks made by Mr. Bolas, said, when this was first mooted, Mr. Campbell Swinton set to work in the same direction, and succeeded in obtaining photographs of various subjects by these means. Through the kindness of Mr. Swinton he had been able to bring up some of his results, and passed round four or five lantern slides and prints. The subjects included one of his own hand, in which a most decided image of the bones was visible, and had been obtained by an exposure of four minutes, with a thickness of black vulcanised fibre between the plate and the hand. Another was that of a living frog, displaying the whole of the bone system, while pictures of coins enclosed in a purse, and a razor in its case, were clearly defined.

Mr. A. MACKIE detailed some of the experiments made by Mr. Gifford, of Chard, and described at the Royal Photographic Society, showing very similar results.

Mr. SNOWDEN WARD, referring to one of these where six brass stops were put in contact with the plate and subjected to the influence or radiations, said two of them showed no sign whatever, but the other four exhibited a sort of half-tone of a circular shape corresponding to the size of the aperture in each, and from them radiated on each side a long halo, one being absolutely at right angles to the other three, which were all in the same direction. These were done without the Crookes tube, Mr. Gifford joining the poles of an induction coil to sheets of copper, and placing the plate between the two. The results were the subject of much comment, it being suggested that something analogous to polarisation had occurred.

Mr. MACKIE mentioned one where an ebonite dish was one of the obstructing articles, the plate showing two long lines exactly corresponding to the ribs of the dish.

STRIPPING FILMS.

Mr. WALL, speaking on this subject, said a method, recommended recently by one of the German papers, was that of treating the film with formalin, which renders gelatine absolutely insoluble, and the film would not stretch.

The HON. SECRETARY proceeded to strip two negatives, as promised, using a solution of the following composition:—

Old methylated spirit	8 ounces,
Hydrochloric acid	½ ounce,
Water	2 ounces,

and mentioned that, with this, he was generally able to strip a plate in a very few minutes.

ANTI-HALATION PLATES.

A question from the box read as follows: "Can any one tell the nature of the colouring matter used in the substratum in Thomas's anti-halation plates?"

Mr. WALL had not examined critically, but believed it to be permanganate of potash, which, in contact with gelatine, is reduced.

PHOTOGRAPHIC CLUB.

JANUARY 22,—About eighty members and friends being present, Mr. H. P. Smith in the chair.

Mr. HEARSON presented a digested and tabulated result of the first

LIMELIGHT-JET COMPETITION,

the main facts of which were, first, that the difference between the strongest and the weakest light was as 100 to twenty-six, and, secondly, that the amount of light obtained was not always in proportion to the amount of gas consumed; in other words, that there were great inequalities in efficiency. Mr. Hearson said that, there having been no measurements of the nozzle apertures, it became difficult to draw anything like a final conclusion. Proceeding to the further series of tests, which he had in hand for the evening, he said that he proposed to adopt a different method of comparing the lights on that evening. Having alluded to the law of inverse squares, and illustrated the way in which the actinic value of a light decreased with the square of the distance between it and an illuminated surface (which point he neatly illustrated with a diagram upon the screen), he proceeded, with the aid of a further diagram, to explain to the meeting the Bunsen method of comparing the shadows thrown by an opaque object upon a screen. He proposed, he said, that evening to adopt a method of comparing the results by which the whole of his audience would be enabled to see the tests, and to declare their own verdict. For this purpose he had prepared two lantern-slide diagrams, which consisted of a scale marked off into inches and tenths drawn on clear glass; he should place one of these (identical) scales in each lantern, and also one of the competing jets. He would then move one or other lantern forward or backward from the screen, until the two scales appeared to be equally brightly illuminated; the comparative lengths of equal portions of the scales would then represent the comparative values of the lights; thus, supposing that the scales upon the screen appeared equally illuminated (the test was, of course, a visual one), if one inch on one scale was represented by one and a half inch on the other scale, the comparative values of the lights would be as one to one and a half. Mr. Hearson added that this method eliminated the necessity for using lanterns with paired lenses. As a result of the series of tests which were then carried out, jet No. 4 and jet No. 1 were declared to be of equal light-giving power, the average value of the lights thrown by other jets being from ·6 to ·75 of the best. The nozzle measurement of No. 4 jet was $\frac{33}{1000}$ of an inch, and of No. 1 jet $\frac{72}{1000}$. Mr. Gwyer, of Bristol, manipulated the former, and Mr. Scarborough the latter.

An interesting feature of the competition was that an injector jet drawing house gas showed a very high efficiency, possibly only limited by the fact that the manipulators were short of a high-pressure tap and connexions. An ether separator of an ordinary commercial pattern, which was informally tried after the meeting was over, was thought to be equal to the best mixed jet shown during the evening.

Formal votes of thanks to Mr. Hearson and the gentlemen who had brought jets for competition were passed by acclamation.

Croydon Microscopical and Natural History Club (Photographic Section).—January 24.—A paper on

VENUS PAPER AND THE VENUS TONING AND FIXING BATHS

was read before this Section by Mr. C. H. BURNABY SPARROW, Mr. A. S. Wild in the chair. Mr. Sparrow said that the paper he was bringing to the notice of the members was called Venus because of the very beautiful result obtainable with it, and that it was prepared by an entirely new process, which rendered it the most permanent of any silver papers. so much so, that nothing short of the destruction of the paper itself would cause destruction of the image. The action of even the strongest light appears to have no effect upon the image. He said: "If you examine the prints I have brought with me, you will see that the image is so well on the surface, even with the roughest papers, that every detail stands out quite as well as it does on any gelatine or albumen papers, and, with the smoothest paper, the minutest detail is better rendered than on either of the papers I have mentioned. For prints from negatives of machinery it is considered very suitable, rendering every detail fully, as you will see from the print I show you of the machinery of an electric current generating station. For toning, any good bath may be used; but, as for all plain-surface papers, such bath should be weak. It is very suitable for platinum toning, and a good bath is as follows: Potassium chloro-platinite (15 grains to 15 drachms of water), 30 minims; nitric acid, from 6 to 10 drops; distilled water, to 12 ounces. For this bath printing should be deep, the shadows may even be bronzed, and the time taken is about twenty minutes for a black tone, but in twelve to fifteen minutes a lovely brown can be obtained. But the easiest, and certainly the most rapid, toning process is by means of the Venus combined baths, which are quite new, and, if properly used, give results that may be relied on as absolutely permanent. I may here mention that these baths give excellent colours with gelatine and freshly prepared albumen papers, though, with this last paper, its action is rather slow. For rich warm brown tones, the prints, just a little over-printed, are placed, without previous washing, in the No. 2 bath for three minutes, then in

an extra fixing bath composed as follows: Sodium hyposulphite, 1 ounce; borax (crystal or powder), ¼ ounce; distilled water, to 20 ounces; where they are allowed to remain for about five minutes. This extra fixing bath is necessary, partly because of the richness of the paper in silver, and partly because of the short time they are in the combined bath; and it will be noticed that no change of colour whatever takes place in this extra bath, due to the presence of the borax. For black tones, it is necessary to print very much deeper, and in this case the prints must be thoroughly washed and placed in the No. 1 solution till they are of a deep plum colour, then drained and immersed in No. 2 solution till a silver grey or fine black is attained, the depth of colour being determined by the depth to which the printing has been carried. In this process no extra fixing bath is required. Whichever of these methods is adopted, a two hours' thorough washing in running water is necessary after the final fixing as on this greatly depends the permanency of the resulting prints; and it must be borne in mind that the prints are much darker when dry, so that they appear when wet, owing to the transparency of the paper when it is wet, consequently it is advisable, especially when aiming at the warm tones, not to carry the toning processes too far." Some of the members brought prints, which were most successfully toned by each of the three above-mentioned processes, and, at the conclusion, a hearty vote of thanks was carried to Mr. Sparrow for his most interesting demonstration.

North Middlesex Photographic Society.—January 20.—The election of officers for the year took place, resulting as follows:—*President:* Mr. J. C. S. Mummery.—*Vice-Presidents:* Messrs. W. B. Goodwin and E. R. Mattocks.—*Council:* Messrs. J. Addison, R. Child Bayley, F. W. Cox, A. J. Golding, A. J. Johnson, A. H. Lisett, J. W. Marchant, J. MacIntosh, F. L. Pither, C. R. Steele, H. Stuart, and C. O. Gregory.—*Treasurer:* Mr. H. Smith.—*Secretary:* Mr. W. Taylor, 38, Palace-road, Hornsey, N.—*Assistant Secretary and Curator:* Mr. W. J. Simpson.

Richmond Camera Club.—January 13, Mr. Eonis in the chair.—Mr. R. Child Bayley, R.P.S., gave a lecture and demonstration, entitled

THE SPEED OF A PLATE.

This is a matter of which every photographer should have some knowledge, but, owing perhaps to the deeply scientific covering in which a subject of this kind is usually wrapped, the average amateur leaves it severely alone. Mr. Bayley, however, by the aid of simple language and practical examples, was enabled to make the various details perfectly apparent and very interesting to all. The Warnerke sensitometer, introduced about 1879, was mentioned as the first serious attempt to obtain plate speeds, but it had many defects, to which attention was drawn. Spurge's actinometer, which followed the above, was considered by Mr. Bayley to have a great future before it, although it had so far been very much neglected. The Hurter & Driffield system was then fully gone into, Mr. Bayley showing and explaining the complete apparatus for obtaining the speed number, and, on the conclusion of his remarks, he made an exposure by each of the above-mentioned methods, which, on development, were handed round for comparison.

January 20.—Mr. C. W. Harris gave an interesting address on the subject of

SHUTTERS.

After calling attention to the essential qualifications of a good shutter, he described and showed specimens of a great variety of those now on the market, including Thornton-Pickards, Bausch, and Lomb, Newman & Guardia, and many others. Several other members showed specimens, and gave their experiences, and a useful and practical evening was passed.

Woodford Photographic Society.—January 16, Mr. E. B. Marriage in the chair.—A quantity of literature, supplied by Messrs. Elliott & Co. and Messrs. Thomas & Co., was distributed among the members present. The Chairman passed round a number of slides that had been intensified by various methods. These were afterwards passed through the lantern, and the results compared, but some doubts were expressed as to their permanency. The slides contributed by the Leeds Photographic Society for circulation among the societies affiliated to the Royal Photographic Society were then shown, as well as some by Mr. Malby.

Woolwich Photographic Society.—January 23, Colonel C. D. Davies presiding. Mr. G. H. Moss, of the South London Society, gave a paper on

COLLODIO-CHLORIDE AND PLAIN SALTED PAPERS.

the formula he used being as follows:—A.—Zinc chloride, 12 grains; tartaric acid, 5 grains; citric acid, 5 grains. Dissolve in 1½ ounces methylated sulphuric ether. B.—Silver nitrate, 60 grains. Dissolve in distilled water, 20 minims, by heat; then add 100 minims of pure glycerine, and 4 ounces of methylated alcohol. Add to this 60 grains of gun-cotton, well shake, and add 1½ ounces of ether. This forms a greyish white emulsion of silver in collodion. Add A solution to B in dark room, or by gas or lamplight, a few drops at a time, shaking the bottle well after each addition; after a final shake from five to ten minutes, allow to settle for twelve hours; then filter through cotton-wool, or decant into another bottle; it is then ready for use. The best paper for coating is baryta paper, and the best method of coating it is to lay it in a frame, a sort of wooden dish with its bottom hinged on; the paper will dry in about two hours. Collodion paper prints much quicker than ordinary silver papers; it can be toned in ordinary baths, but his favourite formula is: Acetate of soda, 40 grains; water, 8 ounces; gold chloride, 2 grains; and 3 or 4 drops of saturated solution of chloride of lime. Fixing: Hypo, 1 ounce; water, 12 ounces; fix from ten to fifteen minutes; then wash well for one hour. This paper tones better with platinum than does gelatine paper. It tones very evenly any colour from red to black in one bath. If in a hurry, hot water can be used for washing. Any chloride can be used instead of zinc chloride, but the latter has the advantage of being soluble in ether or alcohol, whereas most others require water, and too much water in emulsion tends to crapiness. The glycerine is added to keep the paper from curling. The emulsion keeps well. Mr. Moss showed some in good condition made in February 1893, and also some prints recently made with the same. This process is as permanent as any of the silver processes, some prints being shown in perfect condition which had been made five years ago. Lantern slides can be coated with this emulsion, but a substratum is required, such as the following:—Egg albumen, 2 drachms; acetic acid, 1 drop; water, ½ drachm. Stir up, and filter after settling down about two hours; add 2 drops of ammonia '880. High temperature gun-cotton should be used, such as supplied by Roach & Co. Do not use the emulsion near gas or other flame. After a short discussion, Mr. Moss gave

THE PREPARATION OF ROUGH AND PLAIN SALTED PAPERS.

His formula for salting is:—Sodium chloride, 150 grains; ammonium chloride, 100 grains; potassium bichromate, 1 grains. Soak Whatman's or Rives paper in above bath from three to five minutes. After drying, sensitise in: Silver nitrate, 1 ounce; citric acid, 150 grains; water, 8½ ounces. Float on this for two minutes, avoiding air bubbles. The paper will then be a light primrose colour; if it does not possess this colour, the resulting print will probably lack vigour. If printing from a weak negative, use more bichromate; if from a hard one, use less. Do not allow the sensitising bath to drop below 50 grains for rough, and 40 grains for smooth papers per ounce. When the paper is dry after sensitising, print but little deeper than required for finished print, tone in any bath, rinse in several changes, and fix in hypo, 1 ounce; water, 10 ounces; ten minutes for Rives, and twenty to thirty for others, according to thickness. It tones easily any colour to warm black, and gives good tones for some purposes by merely fixing without toning, after washing for about ten minutes. Mr. Moss passed round several excellent prints by both processes, which were much admired.

Bradford Photographic Society.—January 23, the President (Mr. Alex. Keighley) in the chair.—Mr. Percy Lund gave an illustrated limelight lecture dealing with

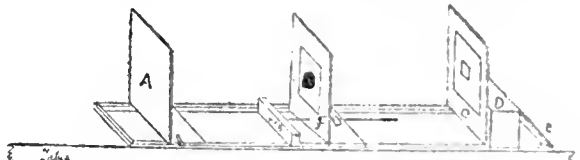
THE UTILITY OF PHOTOGRAPHY.

The lecturer dwelt forcibly on the uses of photography in the arts, sciences, and trades. To the artist, he said, it proved of immense value as a speedy and efficacious method of making rough studies that would aid him in future studio work. To the geologist it truthfully portrayed the different strata, &c., and for the antiquarian it could faithfully record the hundred-and-one historical fragments that would, in the hurry and scurry of life, be otherwise passed by unnoticed. To the astronomer it had proved of inestimable value, rendering truthfully as it does the exact position and features of the heavenly bodies. The business man could use it in many different ways, while to those on pleasure bent it served to bring back souvenirs of places visited. Meteorological and stereoscopic photography were also freely dealt with. Mr. Lund aptly illustrated his lecture with many beautiful photographs, covering a wide range of subjects, the most remarkable being examples of artistic, geological, and instantaneous work. The lecture was listened to with great interest by a large audience, after which a vote of thanks to Mr. Lund, proposed by Mr. O. Nicholson, and seconded by Mr. W. Harmsworth. Mr. R. J. Appleton acted as lanternist.

Derby Photographic Society.—January 21, Mr. G. Walker occupied the chair.—Mr. Willatt was elected a member. Mr. W. Glen gave a demonstration of

ENLARGING.

He showed an apparatus capable of enlarging from quarter-plate to about 20×16, and which was also adaptable for reducing to lantern-slide dimensions from the last-named size by merely turning a winch screw. While not differing in the main from the usual form, it possessed several minor improvements, viz., to facilitate ease of adjustment, and could be worked by day or artificial light, in the latter case a condenser being dispensed with. Amidol was recommended for developing, which, when properly restrained with bromide, and a second addition of sulphite of soda, allowed considerable latitude in exposure. Of course, if a large number of copies were required, it was considered advisable to make an enlarged negative and print in platinotype. Herewith is a rough sketch of enlarging apparatus, together with a description of same. A is the support for focussing screen and carrier for



sensitive plate or paper, being an ordinary oak frame with glass front and removable back, thus doing away with pins, &c., to hold the paper flat. The lens board, F, has the usual rising and side movement; the block, B, fits in a slot, and is firmly held in position by bolts, and may quickly be removed and fixed on the other side of lens board or at E, and the space between A and F filled by a bellows, for which grooves are provided. A is moved by hand, being clamp-screwed when in position. It may be removed and replaced by a travelling platform, carrying a small camera for making lantern reductions. D is board for carrying enclosed lamp, C, of course, being negative carrier. All the travelling parts are readily unshipped and packed flat on the base-board for removal. The annual report and balance-sheet were submitted, showing the Society in a flourishing condition, there being seventy-four members on the books and a balance at bank of 1*l.* 14*s.* 11*d.* Votes of thanks were passed to the publishers of the photographic journals for their kindness in sending copies of their journals to the Society.

Galusborough and District Camera Club.—January 17.—Mr. Nahun Luboshez lectured on

SUCCESSFUL PORTRAITURE AND PLATINO-BROMIDE PAPERS.

Mr. Luboshez began by displaying splendid specimens of platino-bromide enlargements and contact prints. These had been developed with ferrous oxalate, a developer which has much to recommend it, being of established

quality and character, and preferable to alkali developers, as it is not liable to stain the print. It also permits of latitude in the tone of the finished print, hard or soft tones being produced according to the quantity of ferrous sulphate in the developer. This may vary from one in four to one in ten of potassium oxalate. Exposure for bromide prints should be long, that is, the circumstances should be arranged to require a long exposure, so that the percentage of error, in either under or over-exposure may be as small as possible. Use old developer to mix with the new, instead of bromide as a restrainer, and control the development so that the subject may be properly treated to produce exactly the result that is desired. Mr. Luboshez dispensed with a practical demonstration of development, as being a waste of time, and by no means so instructive as personal experiment in the dark room. He, however, showed a toning process for giving a sepia tint to the platino-bromide print. Dealing with portraiture, the lecturer showed, by graphic sketches on the blackboard, how a portrait may be distorted through improper lighting, the action of a ray of light falling on a feature being to force it in the direction of the ray. Though it is not possible to directly realise colours in photography, it is possible to convey the colour tones, by proper lighting and by true gradations in blacks and whites. Most portraits show distortions, but these are removed to some extent by retouching.

Moseley and District Photographic Society.—The inaugural meeting was held in Arnold School, Alcester-road, the premises of the above Society, on Friday, January 24. Dr. Hall-Edwards took the chair.—The following officers were elected:—*President:* Dr. Hall-Edwards.—*Vice-Presidents:* Captain Davidson and Dr. Radcliffe.—*Hon. Treasurer:* Mr. Charles H. Williams.—*Hon. Secretary:* Mr. Fred Coop, Glenwood, Church Road, Moseley; these, with four other gentlemen, forming the Committee. Business being done, slides by Messrs. Baker, Bateman, and Hall-Edwards were passed through the lantern. Slides calling for special attention were *A Figure Study*, by Mr. Harold Baker; *Old Mill*, by Mr. Baynton; *The Mystery of Life*, by Dr. Hall-Edwards, also some figure studies by the same gentleman. The opening meeting started by registering thirty-two gentlemen as members. This Society has decided to encourage the membership of ladies.

Oxford Camera Club—January 13.—A demonstration on enlarging had been promised by the Automatic Company. This, however, had to be postponed owing to the illness of the demonstrator, the evening being devoted to an

EXHIBITION OF LANTERN SLIDES

by various members, with a view to their criticism by those present. Some good specimens were shown, together with some inferior ones; but members were very chary of expressing any decided views as to the merits or demerits of each. This was partly due, perhaps, to the authorship of the slides being known, which introduced the personal element too strongly.

West Kent Photographic Society—January 13.—An address was given by Mr. Lubochez, now representing Messrs. Eastman & Co. The lecturer divided his subject into two parts; in the first he introduced Messrs. Eastman's platino-bromide paper, and showed some very beautiful and delicate life-size enlargements printed on the same. He explained in a brief but extremely lucid manner the methods of exposing, developing, toning, and fixing, found most suitable. The second half of Mr. Lubochez' address was devoted to successful portraiture, and many were the valuable hints he gave regarding exposure and development; but perhaps the most valuable instruction he imparted was on the proper diffusion of light in the studio, and suggestions for an adaptation of the same (to an extent) to outside work.

York Photographic Society.—January 22.—Mr. LUBOSHEZ, of the Eastman Company, added another to his already long series of successful meetings, receiving quite an ovation at the close of his lecture, reports of which have recently appeared.

Glasgow and West of Scotland Amateur Photographic Association.—January 20, Annual General Meeting.—The Council's report showed a membership of 312; funds in bank, 84*l.*; property in rooms valued at 160*l.*, and no outstanding liabilities. A collection of lantern slides made by members was exhibited. The set, numbering about 200, with descriptive lecture, will shortly be offered on loan to the photographic societies of the kingdom, and intimation will be made when they are ready. The pictures illustrate the river Clyde from source to sea, the city of Glasgow, and some of the picturesque districts within easy reach of the city.

FORTHCOMING EXHIBITIONS.

1896.	
February 27-29	Woolwich Photographic Society.
March 2-6	*South London Photographic Society. Hon. Secretary, Charles H. Oakden, 30, Henslowe-road, East Dulwich, S.E.
„ 3-6	*Cheltenham Amateur Photographic Society. Philip Thomas, College Pharmacy, Cheltenham.

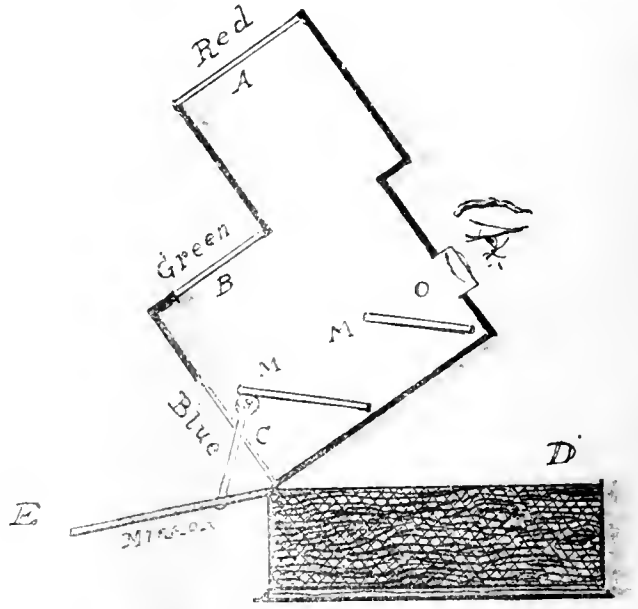
STEREO-PHOTO-CHROMOSCOPES.

To the EDITORS.

GENTLEMEN,—I have just read in the last number of your interesting ournal a report of Mr. Ives's conference at the Camera Club. I think it is desirable that a conclusion as to the value of a photo-chromoscope should not be arrived at without an opportunity of comparing one of these instruments with others. For myself, I cannot estimate the value of the instrument, shown by Mr. Ives at the Camera Club, from the too brief description of it given in your report. I must first see it.

I can only say that there may be other photo-chromoscopes quite as simple as Mr. Ives's that produce equally remarkable results. There is Mr. C. Natchet's, for instance, the interior arrangement of which is suggested throughout the diagram you have published, but it contains two platinised reflecting and transparent mirrors.

The transparency is in about the same position as in Mr. Ives's instrument.



In the above diagram the eyes are at O. M' and M¹ are the two reflecting, translucent mirrors. The pictures and coloured glasses are at A, B, and C. E is an ordinary mirror to throw light on C. M receives the picture A. M¹ receives the picture B. C is seen directly, through M and M¹. D is the stand on which the arrangement is pivoted, in order to obtain the best light possible. The instrument may be arranged for flat or stereoscopic pictures.

I do not know if the polychrome combination of Mr. Ives's coloured glasses tends to produce effects of pigmentary superposition, but I fear so. As regards Mr. Nachet's photo-chromoscope I obtain admirable and perfect effects.

Of course I cannot form an adequate idea of the results obtained with the instrument shown in London, but I cannot allow Mr. Ives's assertion to pass without question that his instrument is the only good one, theoretically and practically. It assumes too much.—I am, yours, &c.,

Paris, January 17, 1896. LEON VIDAL.

SAPIENT SUGGESTIONS.

To the EDITORS.

GENTLEMEN,—What! the dear old boy on the rampage again, and still harping on the same melancholy theme—his lost Paradise. But it was cruel of "Cosmos" to tantalise him by conjuring up a vision that can never become a reality. Honorary Fellowship! I am afraid we cannot manage it for him, much as many of us would like to see his jovial face and hear his cheery voice amongst us again. Even if we could satisfy this last new yearning of his heart, he would still be unhappy. An honorary Fellow is a Fellow without an ordinary Fellow's power to do mischief, and I am sure that would be an unsatisfactory position.

Of course, when our dear old friend writes on "Paradise lost" we do not expect dull ordinary prose from his pen. From a matter-of-fact point of view his language may seem incoherent, but that is because we are unaccustomed to the refinements of so rich and exuberant a fancy. To confound Charles II. with James I. would be an act to be condemned in an ordinary individual, but, with him, it is a feat of inaccuracy that serves the purpose of an embellishment to adorn his literary style, and it improves rather than detracts from the sense of his words. After all, What are facts? Are they not merely shackles to enchain genius? He refuses to be bound by them, and is he not right? Fancy the dear old boy having to think before he wrote or spoke whether that which he was about to say was strictly according to fact. Leave facts for ordinary mortals to deal with and let him continue to entrance us with the lofty flight of his imagination.

But in appreciating the genius of my dear old friend, "An Old Member," I must not descend to fulsome flattery. He is not an ordinary mortal, but still he is mortal, and therefore not all-wise. It was not prudent, for instance, to refer to "hanging exhibitions," for that reminds us of an episode we (and perhaps he) would gladly forget; again, it was not wise to state an opinion that being reasonable never succeeds, for that, of course, is a matter about which he cannot speak with authority from personal experience. Here's good luck to him, and may his shadow never grow less!—I am, yours, &c., ANOTHER OLD MEMBER.

THE PHARMACEUTICAL SOCIETY.

To the EDITORS.

GENTLEMEN,—I fear your correspondent, "D.D.," in a recent issue of your Journal, injures rather than assists the cause of his Society, for the less he says the better, for the trade of this country, where the use of poisonous chemicals or drugs is required, is suffering immensely through the outrageous monopoly acquired by the druggists. When the Poisons Act was passed the sale of chemical and scientific apparatus lay, in a great measure, in the hands of a few leading druggists, who in many cases were well ahead of the mass of the people in culture and intelligence. At that time science, particularly chemistry and photography, was not taught so generally in our schools. Now, our superior education has roused up the latent intelligence and quickened the commercial impulses of our young men, and the consequence is that many have so studied and improved—indeed, in some instances, created—special departments of industry, that dealers and experts have sprung up, and who alone are qualified to deal in the material required. This is particularly the case in photography, as in brewing, distilling, electrical engineering, &c.; hence the necessity for an alteration, and that as soon as possible, in the Sale of Poisons Act. Let the dispensing and sale of medicines containing the poisons of the schedule remain still in the hands of the druggists, but allow the sale of all chemicals and drugs generally to be open and free—except, if thought necessary, the sale of the scheduled poisons be registered as now in the case of druggists. It is very questionable if such a precaution is any deterrent at all, and is, more or less, a nuisance to the public industries. The fact that any of the said poisons can be bought in large quantities from our own wholesale houses, and in any quantity from foreign ones, makes the whole matter a farce. I have also seen in large chemical and glass works, and the same can be said of many of the metal industries in such places as Birmingham, &c., the most poisonous of chemicals used without any precautions whatever, and it would be easy for any would-be poisoner to get from such places an unlimited supply.

My advice to the Pharmaceutical Society is to adapt its rules to modern requirements, asking of any intelligent man or woman to show merely that they know what they are selling—will put any of the scheduled poisons in the prescribed packages, and register the sale if thought necessary. A small fee for registering such a qualification could be insisted upon. The Poisons Act might then remain on the statute, and the Pharmaceutists maintain their monopoly for dispensing, &c. If they do not do this, then the photographic dealers should agitate at once, and I think they will find the country ripe enough now to quash the present monstrous iniquity. That a man like Mr. Hume, with his great intelligence and long experience and practice, should be stopped selling photographic chemicals is tyranny, pure and simple. My experience of a large number of the present druggists is, that they are thoroughly ignorant of the very simplest requirements of our commercial industries, and that from very few of them can be obtained any pure chemicals or drugs, such is the result of monopoly and competition.

If "D. D," quotes the small profits on patent medicines, what about a bottle of simple quinine tonic, containing, say, twenty grains of quinine, in the eight-ounce bottle, for which many, if not most druggists will charge about 1*s.*, and the cost about ¾*d.* for the quinine, five minutes labour, and ½*d.* for the bottle—total, say 2*d.*? He must also remember that Beecham, &c., do all the expensive advertising, and all the druggist has to do is to hand the already-wrapped and labelled article to the customer.

Granted, that Mawson & Swan, Hopkin & Williams, &c., are remarkably qualified druggists, and indeed chemists, but they are only exceptions to the rule. I am well acquainted with the trade, and count many friends in the drug line—men of the highest probity and scientific attainments. I can assure "D.D." that some of my drug friends curse the Pharmacy Act, as they cannot now get apprentices. I consider that, all round, a change in the Sale of Poisons Act would be welcomed, and I vote for it.—I am, yours, &c. J. A. C. O.

BRUSSELS EXHIBITION.

To the EDITORS.

GENTLEMEN,—Will you kindly allow me to announce that the actual opening date of the Brussels Exhibition is March 28

Entry forms duly filled up must reach me as soon as possible after February 1, and the frames should be sent to arrive at my office (carriage paid) on or before March 9.

They will then be dispatched in a joint case or cases, and the carriage there and back will be divided as equitably as possible amongst the exhibitors.

Entry forms will be sent upon receipt of stamps. There are no entry fees, pictures must be framed, but need not be glazed, and only one print in each frame.

There will be no awards, but each accepted exhibitor will receive a commemorative medal.—I am, yours, &c., WALTER D. WELFORD.

15, *Farringdon-avenue, London, E.C.*

SOCIETY FOR ASSISTANTS.

To the EDITORS.

GENTLEMAN,—"Photo" in your last issue asks for a benevolent or protection society for photographic assistants. Like many another photographic worker he calls out in the hour of need for that which, in the hour of prosperity, he might and yet will not provide. Your query is the only answer: "Why do not you and they start a society which seems so much needed?" The opportunity has been given twice through the medium of this column; but, like the Outlanders of Johannesburg, in each case the desiring scores have failed to "materialise" at the critical moment. Must we, therefore, conclude that the photographic workers cannot be organized? I see no reason why they should not be organized. The Assistants' Society of New York is said to be the best and most influential in that city. If in New York, why not in London?

It appears there is 300*l.* going a-begging from the old Benevolent, and I think it would be an act of supreme charity if that sum were granted to form a trade society for the benefit of assistants.

I also believe that such a society, even if worked on strict trade union lines, would, in the course of a year, do more actual benevolent work than did the Benevolent. Contrary to general belief, the trade unions' funds are mainly devoted to relieving distress. For instance, the lithographic printers, a trade closely allied to photography, in 1893, out of an expenditure of about 4000*l.*, spent almost 3000*l.* in sick and unemployed benefit, whilst they spent but 36*l.* in disputes. It is such work that keeps the trade unions going, in spite of very powerful opposition. Why the photographic worker fails to take advantage of such powerful aids in overcoming times of distress I cannot say.

The case of Illingworth *versus* Draycott shows also the need of combination for mutual protection against certain employers, who imagine that their assistants have no legal status, and therefore can be treated in an arbitrary manner.—I am, yours, &c.,

JOHN A. RANDALL.

Answers to Correspondents.

*** *All matters intended for the text portion of this* JOURNAL, *including queries, must be addressed to* "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 2, *York-street, Covent Garden, London. Inattention to this ensures delay.*

*** *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

*** *Communications relating to Advertisements and general business affairs should be addressed to Messrs.* HENRY GREENWOOD & CO., 2, *York-street, Covent Garden, London.*

EXPOSURE TABLE.—A. J. WELLS. Refer to the author's paper on the subject in the JOURNAL for August 23 last. If the point is not explained there, write again.

PLATE-MAKING.—DRY PLATES says: "Can you inform me the name of any books on plate-making?"—In reply: Abney's *Emulsions*, published by Sampson Low & Co., Fetter-lane, E.C.

STICKY BELLOWS.—J. R. India rubber cloth often becomes sticky when out of use. Rub the bellows of the camera well over with French chalk. That is the best thing we can suggest.

COLLOTYPE.—F. G. CASE. The best work on collotype in English is that of Dr. Schnauss, price 5*s.* It may be had from Messrs. Penrose & Co. The collotype process will be the best for your purpose.

LEAKY ROOF.—PROVINCIAL. As the putty is so badly cracked, we suggest that the whole of it be chipped out, the sash bars painted, and then reputtied. It is the only way to make the roof really sound and rain-proof.

COPYRIGHT.—C. BOYLE. It is not necessary that the photographs bear the imprint "Copyright" to make them legally copyright. You must not assume that, because they do not bear the work, you can copy them with impunity. Indeed, the whole of them may be, and probably are, copyrighted.

LENS.—WM. MICHELL. For landscape work, a single lens is as good as the more expensive doublet form. Indeed, many prefer the old single lens, except for its bulkiness, for pure landscape work to any other. The market price of the one you mention would not be more than about five-and-twenty shillings.

SENSITISED LINEN.—BROMIDE says: "We have an inquiry for linen, prepared in the same way as bromide paper, and would feel greatly obliged if you would tell us if this article is made here, and where we might apply."—Communicate with Messrs. Morgan & Kidd, Richmond. If they do not supply it, we know no one who does.

GOLD PRECIPITATING.—H. W. B. If the chloride of gold formed a muddy solution when dissolved, it is pretty clear that impure water was used. It might, however, be that the solution was made in a dirty bottle. In all probability it is useless now for a toning bath. As it was only a fifteen-grain tube, it is very unlikely that a refiner would buy the solution. The quantity of gold it contains is about seven grains—with some samples of the chloride much less.

GELATINO-CHLORIDE PAPER.—GEO. THOMPSON. The reason of the curling of the prints is that you are using too thick a coating of gelatine, and possibly not of the right character. Also the temperature at which the emulsion is applied to the paper may not be quite right, and that would cause the streaks and markings. Try a harder gelatine, and use a thinner emulsion. The most even coating is obtained by employing a properly constructed machine for its application.

COPYRIGHT.—CURATES. Although the song may, as intimated on the title page, be sung in public without fees, that does not entitle you to reproduce it, with the music, as lantern slides for the use of the children, and audience, during the entertainment. Often, where permission is given on the title pages to perform the music in public, there is also a stipulation that it is not to be copied in manuscript, and photographic reproductions would certainly not be permitted in copyright music.

PHOTOGRAPHING BANK NOTES.—R. E. M. writes as follows: "I recently obtained the loan of a thousand pound Bank of England note, made a negative from it, and from that made some lantern slides, which show splendidly on the screen—the water-mark being well rendered. A friends tells me that I have rendered myself liable to prosecution for copying the note, even for lantern slides. As they are on glass, surely he must be wrong?"—No he is not. It is quite illegal to reproduce a bank-note for any purpose whatever, and you are liable to prosecution for the act.

DETENTION OF SPECIMENS.—PRINTER says: "I should be much obliged to you if you could tell me how to get my specimen prints back from a photographer who advertised for a printer. I have written him three letters, and in the first I sent a stamped directed envelope for same, but have had no reply. An early answer through your letter-box of the JOURNAL will oblige me very much, as I do not want to lose them."—In reply: Lay the facts before the Superintendent of Police of the district in which the photographer resides. That course will (or should) speedily bring back your photographs.

TEN PER CENT. SOLUTIONS.—N. T. inquires what these are?—In reply: They are solutions of such a strength that ten grains of the salt dissolved are contained in every hundred minims of the solution. They can be prepared by adding to each ounce (480 grains) of the salt sufficient water to make up a total bulk of ten fluid ounces. A ten per cent. solution of ammonia consists of one fluid ounce of the strongest liquor ammoniæ (·880) diluted to make ten ounces. None of these are actually ten per cent. solutions in the strictest sense which the words can be given, but they are what are known to photographers as such.

ENAMEL COLLODION.—ARTHUR JAMSON says: "I have been making up some enamel collodion with methylated ether and alcohol, but cannot succeed in getting an even film; it is always 'crapy,' like the sample sent herewith. Can you tell me the cause of my failure?"—In reply: The most probable reason is that the solvents are not strong enough, that is to say, that they contain too great a proportion of water. If it is not due to this, then the pyroxyline must be unsuitable. Given a suitable pyroxyline alcohol, 66 o.p., and ether of s.g. ·715, will make an excellent collodion for the purpose. The fact that the alcohol was methylated has nothing to do with it, in all probability, since a first-class enamel collodion can be made with it.

CHROMATE OF POTASH.—FRED. C. writes: "I sent a written order to the chemist's for some chromate of potass, pure, and received a pale yellow salt in very fine crystals, which the chemist avers is what I asked for, while a friend tells me it should be in large red crystals, or it may be in small crystals, but they are always dark in colour. Does the process of purifying in any way alter the colour, or have I been supplied with a wrong article?"—In reply: The salt supplied is, no doubt, *neutral* chromate of potash, while the red salt spoken of is the acid or bichromate, commonly called bichromate of potash. It depends entirely what the salt is to be used for whether you have been rightly supplied or not; the bichromate is the article most commonly employed in photography.

DISTANCE OF SCREEN.—PROCESS BEGINNER asks: "What is the best distance of the screen from the sensitive plate?"—If he asked a simple question like "What is the best exposure for a landscape?" we could answer him, if we knew what sort of landscape it was, and what sort of light, lens, and stop were employed; but, when it comes to the screen question, we should like to be supplied with a few more data before venturing to reply, and even then we dare say that half a dozen different experts would give as many different answers. The best distance of the screen varies not only with the nature of the subject, the exposure, the size of the stop, and its shape, but also with the character of result required, and the distance that best suited a particular "ruling," under certain definite conditions, would have to be considerably modified if the ruling were altered, or a coarser or finer screen employed. Better try a few experiments.

THE BEST DRY PLATES.—W. J. MAINWARING says: "Will you kindly let me know which are the best dry plates to take photographs out of doors?"—In reply: We can hardly imagine our correspondent puts his question seriously; such, however seems to be the case. Our advice to him is to select the plate which experience tells him is best suited for his purpose.

AMYL-ACETATE.—D. MCGREGOR. Amyl-acetate is a very good solvent for most pyroxylines, either alone or with camphor and spirit. It dissolves celluloid freely, and may be used for repairing celluloid or xylonite articles. We are not surprised that your local pharmaceutical chemist never heard of it. It may be obtained from such houses as that of Hopkins & Williams, or, indeed, any wholesale chemist.

APPRENTICING A YOUTH.—C. MCKAY. If you desire to make the youth a photographer, the only thing we can suggest is that he be apprenticed to a good house, where he will be properly taught those branches of photography that he desires to become proficient in. There is no fixed rule as to the amount of the premium, or the length of the term of apprenticeship; that is quite a matter of arrangement. Of course, the best houses require the highest premiums.

GREASE SPOTS ON COLOURED PICTURE.—A. MILLER says: "Some oil has got splashed on a coloured enlargement that was waiting to be framed through the carelessness of an assistant. I think I have read of some means of taking grease spots out of prints, but cannot recollect where. Can you enlighten me? The picture is a bromide, coloured in water-colour, and the oil ordinary sweet oil."—The method has more than once been given in this column. Drop some pure benzole on the spots, allow it to soak in for a few seconds, and then blot off with clean white blotting-paper. Then apply more benzole, and again blot off. Repeat the application till the grease is removed. If pure benzole be employed, no stain will be left, and the colours will not be disturbed.

MOUNTING AND DEVELOPING.—A. A. ROBINSON writes: "Would you be so kind as to help a novice in two small matters? 1. The first difficulty I wish to consult you about is with regard to mounting Ilford P.O.P. I have been recommended to squeegee the prints after their final washing on glass. This, of course, prodnces a very shiny surface, but I cannot manage to retain this unless I paste the edges only on to the cards, which is both awkward and clumsy. 2. My other fix is with regard to developing. I use Ilford ordinary plates and pyro-soda developer, but find that, before I have got the dark shadows out, the high lights are so dense that, when printing, I have to sacrifice one or the other."—1. If the waterproof backing—to be had from all the dealers—be used, the gloss will be retained. 2. The negatives are under-exposed. Give more exposure, and the plates will develop more harmoniously.

SPECIFIC GRAVITY BULBS.—WENTWORTH asks: "Is it absolutely necessary that the specific gravity bulbs recommended for taking the strength of ammonia by Mr. Haddon be of glass, or rather is a glass bulb the only form in which the principle can be applied? My reason for asking this is that I was amused on seeing an ingenious youngster of my acquaintance adjusting his ammonia solution by means of a small cork float to which was attached by means of a fine wire a leaden weight. He assured me that, after carefully adjusting the balance between the cork and the lead, which he had done by comparison with a hydrometer, his home-made appliance was just as good as the other, and certainly in principle it would seem so. Is it?"—It matters not of what material the instrument is made, provided it is, in the first place, accurately adjusted and not liable to change or variation. In the latter respect glass has the advantage most decidedly over cork, lead, or, indeed, any metal; but, so far as the principle is concerned, the cork float is equal to the glass bulb.

CHLORIDE OF COPPER.—J. F. G. says: "I have been recommended to use chloride of copper for toning transparencies, bleaching the image first and redeveloping with whatever developer will give the tone required. In a back number of the ALMANAC I came across a formula for making the chloride in which it is spoken of as a white insoluble powder, whereas a small quantity of solution given to me by the friend who recommended it was greenish-blue. How is the white powder got into solution if it is really insoluble?"—The formula in question was apparently copied from a foreign source, and refers to cuprous chloride, or subchloride of copper, and not cupric or perchloride, which is the salt required. The latter forms green crystals when in the hydrated state, or brown when anhydrous, and is very soluble and deliquescent. If not readily obtainable, it is easily made by dissolving together sulphate of copper and common salt in the proportions of about two parts by weight of the former to one of the latter. The resulting solution contains chloride of copper, and its strength is immaterial provided it is strong enough to bleach the image.

INSTANTANEOUS EXPOSURES BY HAND.—PHOTO-CYCLE says: "Do you think it possible by practice to expose rapidly enough by hand for ordinary subjects, so as to dispense with the use of a shutter, which I find always to be getting out of order? A friend of mine says it is, and, in proof of his statement, showed me a picture of two cyclists racing at full speed past the camera, both of them being sharp enough to be easily recognisable. I can't manage it myself, although I have tried very hard."—Ask your friend to let you see him repeat the operation, then believe him—not till then. A very little calculation will show the absurdity of the thing. At racing pace the cycles would be passing at a rate of, say, thirty feet in a second, and at such a pace, in order to secure sufficient sharpness for the figures "to be recognisable," the exposure would have to be certainly not longer than the one-hundredth part of a second, and that would mean a movement of about one-third of an inch. It would depend upon the distance from the camera how far "recognisable" the figures would be then; but do you imagine that mere manual dexterity could effect such an exposure? It is, we repeat, absurd.

THE BRITISH JOURNAL OF PHOTOGRAPHY.

No. 1866. Vol. XLIII.—FEBRUARY 7, 1896.

Contents.

EX CATHEDRÂ.

We are in complete sympathy with the objects of the National Society for Checking the Abuses of Public Advertising, the annual meeting of which was held last week, and at which such speakers as Alfred Waterhouse, R.A., William Morris, W. B. Richmond, R.A., and other men of artistic light and leading lifted their voices in protest against what was termed "the destruction and degradation of natural beauties" by ugly advertisement boards. There was encouragement in the fact, said Mr. Waterhouse, that a decided check had been put on field advertising, which at one time threatened to leave no beautiful spot undesecrated.

* * *

In this, only one of the many abuses the Society is laudably working to remove, landscape photographers are, or should be, so peculiarly concerned that we are surprised the Society has not received the co-operation both of individual photographers and photographic societies generally. The prevention of urban defacement, due to the boards, posters, and sky signs of enterprising advertisers, is a matter that must be approached by the light of modern utilitarianism and commercial requirements, and is therefore beset with difficulties of a more or less insuperable character. With regard, however, to the dotting of English landscapes with huge boards advertising pills or ointments, the volume of the outraged artistic sense and sentiment of the community is so overwhelming that it is only with difficulty their further existence can be allowed to tarnish nature and offend the eye.

* * *

We wish the Society every encouragement and success in its endeavours to stem the tendency that undoubtedly exists to turn public beauty spots into so many backgrounds for the blatant boastings of quack-medicine vendors. A bill designed to stop this wholesale disfigurement of the country-side is to be brought before Parliament, and if, as we hope it will, it passes and becomes law, there is not a lover of nature in the land who will not feel grateful to the Society, whose supporters should include every photographer.

* * *

The veteran photographer, optician, and mechanician, Mr. F. H. Wenham, sends us this week an article entitled *Electrography, or Images obtained by Induction* (see page 84), which will be read with great interest by those who are interested in the Röntgen method of photographing with the X rays. Mr. Wenham points out that electrical luminosity is not essential to the production of chemical action on a sensitive surface, and, quoting some experiments of Dr. Draper, of New York, made in 1840 in obtaining images on Daguerreotype plates by means of the action of the discharge from a Leyden jar on opaque bodies, says that Röntgen's work appears to have been to some extent forestalled by these long-forgotten experiments.

* * *

In connexion with the same subject, Mr. W. Brooks draws our attention to the fact that, in March 1877, he read before the South London Photographic Society a paper entitled *Magneto-photography*, and printed at page 112 of our volume for that year. In this paper Mr. Brooks described some experiments by which he got an image in total darkness in a shut-up box. He experimented with an ordinary horse-shoe magnet about eight inches long which he placed in a box, poles uppermost, and, three-eighths of an inch above the poles, a card perforated with lettering. The plate was placed one-eighth of an inch above the card, which was blackened. An exposure to the magnet in total darkness for fifteen minutes gave an image

on development; but the strangest part was that some almost invisible lettering on the non-perforated part of the card also developed up. Mr. Brooks informs us that he proposes resuming his experiments.

* * *

The humourists have, of course, seized upon the Röntgen method of photography as a vehicle for the display of their wit and fancies. An esteemed correspondent, Mr. C. H. Crosby, of Chicago, writes us as follows, under date, January 20:—"By to-day's mail I send you part of copy of *Chicago Tribune*, of yesterday, with account of a very astonishing (?) advance in photography. I presume same is a 'fake' or humbug. At your convenience and pleasure, will you please tell us about it."

* * *

By this time Mr. Crosby will have learned that neither "fake" nor humbug has anything to do with the wonderful power which the X rays have of conveying to a plate a developable image of an object through an opaque body. Our Chicago contemporary prints blocks of the now familiar hand, the contents of a purse, &c., and also makes the following remarkable statement, which is also illustrated:—"Perhaps the most notable experiment related, which illustrated with graphic clearness the eccentric power of the new discovery, was the photograph of a man seated beside a young lady before the photographer in ordinary dress, but whom the negative shows a perfect skeleton. To test the clearness with which the new process would reproduce the skeleton of a living subject, negatives were also taken by the ordinary method. In the first case the spinal vertebræ were reproduced in every detail, forming a ghastly specimen of realism."

* * *

The X rays, so far as we have been able to learn, are not claimed by Professor Röntgen to betray such discriminative gallantry as that which our American contemporary infers them to possess. The illustration shows the skeleton to have his arm round the lady's waist, and not visible through it, a fact which dispels any attempted explanation that two exposures were made. But, of course, the experiment referred to was not actually made.

* * *

In view of the interest excited by the topic of the hour, the last number of the Royal Photographic Society's Journal is especially valuable. Mr. J. W. Gifford's two papers on *Photography through Opaque Substances* are given, with several illustrations, the latter of which are of an interesting nature, two of them being from shadowgraphs produced without the intervention of a Crookes' tube. The number also contains a full description of the new Stigmatic lens by Mr. Aldis.

THE RÖNTGEN RAYS.

Since the first days of photographic discovery no such excitement has been caused in the scientific and popular press as that produced by Professor Röntgen's recent discovery. The daily papers and illustrated periodicals contain voluminous reports of what Professor Eder has called a "new form of energy," and "one of the most important discoveries of the century." The whole public are familiar with the reproductions of the pictures obtained by that *savant*, and his numerous imitators. Broadly speaking, what he has discovered has been the power of certain radiations (using the term in a wide sense) to affect photographic films, though screened by objects hitherto considered absolutely opaque, that is to say, opaque to such light or spectrum radiations that have yet been experimented with. Nearly all bodies are permeable, more or less, by this agent, which meanwhile he has termed X rays. For some time after the publication of the discovery attempts were made to show that the same effect had been produced years ago by other investigators, but it seems to have been accepted that the X rays have been discovered by Röntgen alone. So strongly is this felt, that at the meeting of the Paris Academy of Science of January 27 Professor Koellicker's proposal that the new rays should for the future be called Röntgen's rays was received with acclamation.

Röntgen rays penetrate most substances, though the transparency is not complete. During the examination of many substances it was found that the photographic power of the rays passing through them diminished in power with increase of thickness of the material experimented with. Some objects, however, are almost opaque to the Röntgen rays. To use the discoverer's words, his detailed experiments "lead to the conclusion that the density of the bodies is the property whose variation mainly affects their permeability." Bone is almost opaque to them, muscle fairly permeable. Hence, if a hand be laid on a dry plate and exposed to the new rays, they pass through its fleshy part without much loss of power, but do not pass through the bone, and, in consequence, a developable effect is produced. No effect is produced underneath the bones, but outside them the radiations act, hence a negative of the bony structure is brought out upon development. This of itself is nothing remarkable, for, if a strong light from an ordinary source were concentrated on the hand, there is no doubt that a somewhat similar effect would be produced, and in a much shorter time. But the peculiarity shown with the new rays is as follows: First, it is immaterial whether the plate be placed in a closed dark slide or in a box of aluminium, of ebonite, or of many other substances, the action takes place equally well as the rays penetrate them; and, secondly, while with sunlight, &c., acting on the hand, the skeleton print would be "fuzzy" through the flesh diffusing the light, with the Röntgen rays no diffusion takes place; they pass equally well, for example, through muddy water as through clear. This is a point of paramount importance to bear in mind when endeavouring to gauge the future possibilities of the "new photography," as it has been termed.

If our explanation has been followed, it will be perceived that the results so far obtained are not photographs in the ordinary sense of the word, they are merely photographed shadows. Indeed, most of the published accounts now speak of them as shadow photographs or shadowgraphs. At this stage we would like to make a suggestion as to the term to be used in describing them. Shadowgraph is certainly a short word, but is contrary to all rules of etymology. Our suggestion is that the new pictures be called sciographs, which would be expressive enough without a further addition of "photo."

We may now dwell a little upon the manner of producing the new rays. Though Messrs. Swinton & Stanton had little success with this method, their discoveries clearly enough state that they passed the discharge from a large induction coil through a Hittorf's vacuum tube, or a well-exhausted Crookes' or Lenard's tube. By the bye, our good friends on the Continent are rather given to ignoring the English inventors in naming apparatus. Crookes' radiometer (to the invention of which all their discoveries are really indebted) was very quickly imitated in Germany, whence we had

Geissler's tubes." Crookes' tube is a highly exhausted bulb or tube, in which are fused two terminals of metal. When the current, as above, is passed through, these negative and positive terminals are surrounded with a glow. The cathodic rays we read so much of are simply those from the negative poles. Crookes' tubes are made to contain varying substances, which fluoresce in the rays. Röntgen's rays are those emitted by the fluorescing substance where excited by the cathode radiations. Glass is not very transparent to them, so that their actual photographic power is much diminished in passing through the glass walls, and it is proposed to substitute aluminium for that portion of the glass that intervenes between the emanating Röntgen rays and the sensitive plate. So far, nothing has been found which will decidedly deflect or reflect them; prisms and lenses have no effect in the hands of Herr Röntgen and others, glass, bisulphide of carbon, paraffin, and other bodies having been tried. By placing certain pieces of metal on the glass side of a dry plate, and then passing the new rays through the film, there was a darker impression above these pieces of metal; this would appear like a reflection, but Professor Röntgen cannot pronounce it a case of reflection.

Though the new photographs may be pronounced "mere shadow pictures," it is evident that they are at least comparable to microscopic images of an object illuminated by transmitted light which, as every one knows, are only really sharp in one plane, but are yet capable of giving invaluable records on the photographic plate.

This is briefly how the matter stands at present. The direction in which further progress may be expected is first in getting a stronger radiation by using a transparent substitute for the slightly transparent glass, and by increasing the intensity of the initial radiations. Secondly, by obtaining a figure exceeding in sensitiveness those hitherto employed. Possibly Professor Schumann's film might prove more sensitive. Thirdly, by experimenting with a large variety of substances in the endeavour to find one that will reflect or refract the rays. If such could be found, a great increase of rapidity would be obtained, and intense sharpness could be brought about by reducing the emitting radiant to a point, although the sciographs so far produced are remarkably free from penumbra. Again, variations of temperature of the plate, or the medium through which the rays are allowed to pass, may materially alter the ratio of impressibility, or possibly lead to discovery of refraction or reflection.

We cannot conclude this survey without referring to two other remarkable sets of investigations suggested by Röntgen's work. At the meeting of the Paris Academy as above, M. d'Arsomval describes some experiments made by M. Gustave Lebon. He stated that the radiations from an ordinary petroleum lamp flame were capable of influencing a plate though covered by a sheet of iron about an eighth of an inch thick if exposed for tw or three hours. It is proved that it is not heat rays that produce these effects.

Finally, we may refer to the letter in the *English Mechanic*, over the signature of David E. Packer, Astro-Physical Station, S. Birmingham. It states that, "from innumerable experiments made during the last six months, it has been found that metallic plates, foils, and films are relatively transparent to solar radiance of high refrangibility, and that photographic plates screened by such media during exposure to direct sunlight are affected in proportion to the thinness and electrical conductivity of the interposed screen." Pinholes instead of lenses gave splendid results of the solar corona.

Height of the Barometer.—Three weeks ago we called attention to the abnormal height the barometer had registered in London, 30·92. Since then it has attained the same height in the metropolis. It is stated that on only five occasions, during the last hundred-and-twenty years, have the readings exceeded 30·9, and it is a curious circumstance that two of those occasions should have occurred within about three weeks of each other. High readings of the barometer, in the winter, are not always propitious to photography, as they are usually accompanied by calms and fogs, and that was the case last week.

Price of Engravings.—Last week there was a two days' auction sale of rare old engravings, by Messrs. Robinson & Fisher, at their rooms in King-street. It is interesting to record some of the prices realised. An *Apollo and the Nine Muses*, after Cipriani, by Madame Bovi, fetched 48*l.*; *Mrs. Fitzherbert*, after Cosway, by J. Conde, 18*l.*; *Guinea Pigs*, (two) after Morland, by Bartolozzi, 36*l.*; *Lord Gordon's Children*, after Sir Joshua Reynolds, by Simon, 43*l.*; *Louisa*, by J. R. Smith, 45*l.*; *What you Will*, in colours, by the same hand, 53*l.* 11*s.*, &c. It is not at all surprising that fine examples of the old line and mezzotint engravers realised such good prices as they did at this sale, for both styles of engraving may now almost be looked upon as a lost art. The old masters of it have died off, and no new ones have been trained to take their place, and it is very doubtful if there will be in the future. Photogravure cannot well be charged entirely with bringing this about, for, long before it got a firm hold, there were but few engravers of the old school in existence, and the majority of those had passed their prime. Each year will therefore add to the value of engravings by the old masters of the art.

Ugliness in Art.—A well-known writer in this month's *Nineteenth Century* complains that artists are losing, to a great extent, the power of appreciating the beauties of nature: and the fault is attributed to the want of loveliness in the ordinary surroundings of modern life. It is asserted that men living in Cromwell-road, Kensington, or in any similar thoroughfare in London, or a Continental city, have their ideas dulled and dwarfed by the atmosphere around them, "and this perversion of natural instincts in them makes the tendency to replace beauty by eccentricity and by weirdness fatally frequent;" and we learn, too, that their critics obey the same influences, and that "modern criticism is characterised by what appears to be a total incapacity to appreciate the quality of beauty, a total insensibility to its absence from modern art." We fear that the charge is too true, and most thoughtful persons will agree with us, especially if they happen to have visited the Dudley Gallery at the time that the New English Art Club have temporary possession of that Egyptian temple. Possibly too, when the Photographic Salon hold sway there, pictures may be found on those walls in which beauty is conspicuous by its absence. It is strange that so much ugliness in art and photography should gravitate to that room in Piccadilly, and our only consolation is that the gallery is not a big one.

A Novel Studio Accessory.—Many of our older readers will, most likely, remember that some two or three decades ago there was an amusing controversy in the photographic press about a picture that was shown at one of the Society's Exhibitions, in which a seagull was depicted on the wing. The point raised was whether it was a living gull, or only "a gull on the public," as, at that period, the collodion process was the most sensitive one in vogue. Recently a gull—a real seagull—in connexion with photography, has been engaging the attention of gentlemen of the long robe in the Law Courts. It appears that a photographer, Annie Simpson, had tamed a seagull. It would answer to its name, come when called, would take food from the hand. The bird was, and probably is, still used by its owner in her business. The lady was summoned before the Justices sitting at Buxton for cruelty to the bird by cutting its pinion. The Justices, though thinking there had been cruelty to the bird, dismissed the summons on the ground that the bird was not a domestic animal within the meaning of the statute.

Against this decision an appeal was heard at the Law Courts a few days ago, with the result that it was dismissed, the Judges holding that a seagull is not a domestic animal.

During the hearing of the case in the Court of Appeal, one of the learned Judges (Mr. Justice Williams), in reference to the bird being used in the business, remarked that "a stuff-d bird would do as well as a live one for the photographic pictures." To this the counsel for the appellants replied, "No; for any one could see in the picture whether it was a stuffed bird or a live bird." That is not all, however, as there is a novelty in having a real live bird as an accessory which is not the case with a stuffed one; and there is little doubt that it does add to its mistress's business, notwithstanding the alleged cruelty.

A New Engraving Process.—One day last week, Professor Heromer gave a demonstration at the Fine Art Society's on his patented method of producing engraved plates. This method has been duly lauded in the lay press, and hy artists, because it preserves the actual touch of the artist himself. The method is this: A copper plate is silvered on the surface: on this the artist paints his picture in a particular kind of black ink, then, while the work is tacky, it is dusted over with a certain powder which is said to adhere in a discriminating way; the coarsest particles adhering only to the deepest shadows, and the finest only to the delicate tints this powder also gives a conducting surface. After the superfluous powder has been dusted off an electrotype is made, and that forms the printing plate.

Some little mystery is made, in the reports we have seen of this process, as to what the special ink and the powder is composed of. We find, on reference to the specification—Herkomer & Cox—that the ink is composed of almond and castor oil, mixed with German or lamp-black—equal parts of the two oils and the black. The powder is composed of equal parts of asphaltum and copper-bronze powder. The latter gives the conducting surface. We may have something more to say on this method of producing printing plates, as compared with some other processes at an early date. *Apropos* of a letter, in a daily contemporary, from Mr. Wedmore, extolling the process, the following amusing letter "descriptive" (?) of the Pretsch process, appeared in the *Standard*, which will, doubtless, raise a laugh with those familiar with that process:—

"The New Artistic Process. 'Sir,—Mr. Wedmore's letter in the *Standard* of to-day carries me back to the Fifties, when Herr Paul Pretsch, an Austrian *savant*, established himself in an old house in Holloway, where there were gold fish in a pond in the garden. (All this helps the memory.) He took his *positives* on the roof, which looked like a small light-house, then spread his *viscid red mixture upon a glass plate over the picture, and when dry got a depressed replica upon a gutta-percha mould.* This mould was then carefully levelled *by a spirit machine, and the nitrate of silver solution poured over it,* after which he got a matrix to print from by *hanging the mould in the acid bath with the voltaic attachment.* He called this a photo-galvano-graphic process.'" [The italics are ours.]

ELECTOGRAPHY, OR IMAGES OBTAINED BY INDUCTION.

The recent accidental discovery seems to be based upon a misconception that light, or some hitherto unknown modification of it, has something to do with the effect. A Crookes-vacuum tube in a state of electric luminosity is not at all essential; a sparking coil, or a Wimshurst influence electrical machine, would be preferable. It is well known that, if a body is charged with static electricity, such as the prime conductor of an electric machine, it will induce a charge, or, if uninsulated, a current of electricity in all surrrounding bodies, and these, again, will influence and charge other bodies, even through plates of intervening substances. These conditions may be quite unaccompanied with any degree of luminosity, yet it may be taken for granted that they exert a feeble chemical action on a highly sensitive plate, and interposed bodies, or substances of different surface structure, or parts of varying inductive capacity, will develop a structure otherwise invisible and unknown.

In connexion with this subject I take the following extracts from the experiments of Dr. Draper of New York, published in the *Philosophical Magazine* for October 1840, premising that the old, slow Daguerreotype process only was known at that time:—"I was desirous of ascertaining if electricity had any similar effect. The coins and medals upon it (the sensitive plate) were submitted to discharges from a large Leyden jar. On exposing it to mercurial vapour, the impressions were very prettily brought out. . . . . With a view of ascertaining the distance at which bodies might be copied I placed upon a plate of polished copper a thick piece of plate glass, over this a square of metal and several other things, each being larger than the body beneath. These were all covered with a deal box, which was more than half an inch distant from the plate. Things were left in this position for a night. On exposing to the vapour of mercury, it was found that each article was copied, the bottom of the deal box more faithfully than any of the others, the grain of the wood being imaged on the plate. . . . . I feel convinced that we have to do with some thermic influence, and that it will eventually be found that some purely calorific excitement produces a molecular change, or that *a thermo-electric action is induced which effects some change in the polarities of the ultimate atoms of the solid.*" (Italics mine.)

It appears, therefore, that the subject has to some extent been forestalled by these long-forgotten experiments: I may mention a fact familiar to most photographers. Oftentimes a piece of sensitised paper has been placed within the pages of a book in order to preserve and shield it from the action of light, and been forgotten for some days. It will then be found that the whole of the printed matter has become transferred to the sensitive paper, so as to be distinctly legible. This phenomenon has been peremptorily dismissed, with the assertion that the silver has been reduced by the action of the carbon of the printer's ink. As *absolute contact* is not necessary to produce the impression, I was never satisfied with this explanation, as it cannot be imagined that there is an ever-continued exhalation of carbon from the ink; therefore some other reason is required, and Professor Draper's electric suggestion is probably the correct explanation. Some paper, when rubbed, is highly electric, and it might be worth while to place the sensitive photographic surface beneath sheets of paper that have been excited by rubbing, and so ascertain if the effect is enhanced or the time of exposure shortened.

No one will now incur the hardihood of repeating the old challenge of the clairvoyants of spreading a bank-note at the bottom of a box to be presented to any one that can tell the number without opening the box.

F. H. Wenham.

DIGRESSIONS.

II.—Limitations. The Nude.

Although I do not disagree with the principle expressed in the words, "Liberty for All," I know that liberty is all the better for a little restraint, and that it makes as much for progress to know what *not* to do as what to do. A brilliant flash of silence has been known to have more effect than most eloquent speech, and there is more artistic satisfaction in the simple breadth of a luminous twilight than in the noisy and multitudinous detail shown under the mid-day sun. Over-elaboration is a frequent destroyer, and a painting is sometimes at its best long before it is supposed to he finished. Art is to some extent suggestion. Occasionally, however, the highly finished reigns supreme, but it is by aid of other and greater qualities. It is possible to have too much performance to leave room for promise, and there is much poetry in promise. A few scratches of an etching needle may show more genius than an altar piece, though this great truth has been much depended upon and worked by charlatans.

Most excellent work is sometimes thrown away because bestowed on a wrong object, and, to come to our own art, very perfect photography is often wasted in a mistaken direction. Indeed, in photography it is becoming more and more a matter of serious study what to do and what not to do.

Admitting that there seem to be no bounds to the application of mechanical photography, there are many limitations to its artistic application that should be recognised and acknowledged.

Here is a quaint example. In a recent number of one of our favourite American photographic magazines, the author of an illustration excuses the badness of his picture by explaining that "the day was terribly hot, and the poor cow was tormented by legions of flies, and we found it impossible to get the composition we wanted." Now, surely the artist lost sight of several lawful limitations. The first was that the picture should not have been taken at all in such weather. A cow tormented by legions of flies should not have been selected as a subject for pictorial treatment; moreover, if the photographer cannot get the composition he wanted, and he fails to realise his intention, he should not ask our acceptance of some inferior want of intention. In this case the photographer rightly gives the production up as a work of art, but he does not explain why the negative, which was not what he wanted, was not destroyed at once. I suppose not one in a hundred negatives survives its birth, but there is still nothing like enough destruction done. The negative to which I have referred was not all waste. Nothing is wasted in America. On the principle, I suppose, that Providence brings nothing into the world without some good purpose—not even sugar-candy or the new developers—failing as art, the photographer turns his negative to use, and concludes his explanation with the usual tag to American illustrations, an advertisement.

"But it speaks well for C——'s plates with metol developer." Here ought to be another limitation. One of the things most calculated to knock all poetry out of a work of art is turning it into an advertisement of the material of which it is made, like a Mellin's baby.

Turning over the American magazines, we occasionally come to a lovely portrait or *genre* picture, and, of course, want to know the name of the picture and the producer. For a long time the young lady sitter seemed to be christened, in very large letters, "Aristo" or "Ilo," or some such names, which showed a want of originality in the artists. Now she is "Somebody's Half-tone." Then the cows and sheep began to bear the same names, and further investigation showed that the names meant the paper or the plate used in their production. I am glad to see that at least one of the American papers, the *Photographic Times*, has given up the practice, and respects art.

It is possible to get into two minds over the limitations of our art. On the one side I want all possible liberty; on the other, I have a feeling that no artist, in whatever material, should transcend the bounds of the process which he has adopted. The end should be truly adapted to the means. "One of the most striking signs of the decay of art," says Goethe, "is when we see its separate provinces mixed up together. The arts themselves, as well as their varieties, are closely related to each other, and have a great tendency to unite, and even lose themselves in each other; but herein lies the duty, the merit, the dignity of the true artist, that he knows how to separate that department in which he labours from the others, and, so far as may be, isolates it." However, it is not fettering liberty to endeavour to prevent one method or style competing with another, or to save ingenuity from taking false directions.

Taste has improved the world by limiting different materials to their own natural appearances—wall paper, for instance, no longer pretends to be wood or marble—without limiting art, and I don't know that it is necessary for photography to look like the results of any other art. On the other hand, it need not insist on the brand of its calling; there need be no insistance on its looking aggressively photographic. Each art should respect its own individuality, but not worship it as a fetich.

Photography can only represent what is before it. If we are to accept this stereotyped saying, which we will for the moment, it helps to clear away and place outside our boundaries many things that are not worth sighing for, and better out of our way. It clears off all the past, the dead and gone and vanished. The true artist in all materials has still something of the "vision and faculty divine." Much is denied to us in poetry, history, and legend—we are not allowed to guess and call it true; but we have plenty left, and shall have more when we have eyes to see. But the photographer should always keep in mind that, if, in the nature of things, he is bound to have his object before him, he is not bound to see it as others see it. Indeed, I do not think any two photographers can see or represent precisely alike. Individuality is bound to come in, and a very little variation seems to make all the difference. There is that curious instance, which will be a precedent, in the last Pall Mall Exhibition of two pictures of the same subject, under similar conditions, of nearly the same size, hung close together, the only serious difference seeming to be in the title; yet the Judges were able to detect a variation—some subtle poetic aroma, perhaps—in one of them which made it worthy of a medal, and the other unworthy.

It is the business of the artist to see beautifully, and to show men what they might see if they also were artists.

But, whatever limitations we may find prudent in our practice, we should allow none to its possibilities. We should use our limitations only for convenience and to simplify our work. Within ordinary bounds, the art has much more flexibility in its technique than some critics will allow themselves to believe; and science has done much to retard the true interests of photography, except as a handmaid to other arts and many trades. Here is a new instance. Artists are now proving that carbon prints can be developed from the front. Science has been telling us for years that this is impossible, and now says—at which we smile—that, if it is possible, it is a modification of something suggested nearly forty years ago by science, and that its excellence depends on a defect!

What is it that suggests that some remarks on the nude in photography would be in place here? Ought it to be one of our limitations, or would that demand be too narrow?

In the present age and condition of the world, the nude in photography is an anachronism, except in the uncivilised portions thereof. The nude still exists among savages who have not yet been civilised out of their taste for the manners and customs of Paradise as we are taught they existed; but it does not seem up to date for young gentlemen to walk about undressed, and for young women with wasp-like waists and distorted toes to disport themselves "mit nodings on." The nude and the undressed are different things; these figures would be not so much nude as undressed. To some people this would mean the same thing, but "oh, the difference!" I do not say this out of any consideration or respect for Mrs. Grundy or her tribe, it is a matter of art. The nude is the divine ideal; the undressed is the modern naked girl, and, like the angel with the vicar, she makes no apology for her impossibility; and, as I have suggested before, the impossible is an established limitation.

The nude has no excuse if not beautiful; the modern nude is not beautiful. By the bye, if anybody wants to prove that it is, photographic evidence will be accepted. If many people were asked what was the most beautiful thing in the world, they would say without hesitation the Venus of Milo; the other end of the scale is the modern model for what Trilby calls "the altogether." The least touch of imperfection in the form, or awkwardness of motion, and down comes the ideal to earth, and is of the earth, earthy.

There is too much realism in the photographic nude. The nude belongs to poetic art, and in this, above all, we must accept strong conventions. The object is not nakedness, but an opportunity for the display of graceful lines and forms, delicate shades, and gradations; the subject must be many planes above reality. Absolute realism never succeeds. Effort is now being made to introduce "real conversation" on the stage; but it only succeeds—if, indeed, it does succeed—in afternoon-tea comedy. The poetic drama must be in verse of some kind; so also must the nude be idealised, and who can idealise a modern waist or a distorted foot—or, indeed, any human form marred by artificial devices? It has been wisely said that the ideal is the blossom of the tree, realisation is its fruit—and sometimes the fruit sets the teeth on edge.

The only excuse, then, for the nude is beauty, to which may be added the skill with which it is executed in line or colour. It is too late for a photographer to claim credit for any great amount of beauty of execution; there is no opportunity of showing beauty of colour, and beauty of line is handicapped by want of beautiful

models. Fashion has destroyed nature here. What it has done is clearly explained in the familiar punning verse:—

"It matters not, though doctors may
Declare that it will kill,
The awful corset's here to-day,
And stay of corset will."

Moreover, if perfect models were possible to make the nude in photography acceptable, we should want the universal artistic refinement of the Greeks or the indifference of the savage. We hold a middle place, our cultivation is too artificial.

Just a final word. It comes as a matter of course for some people to say "studies of the nude would be so useful to the artist," meaning the painter or sculptor; meaning those who ought to be quite competent to paint or model for themselves. For my part, I would no more offer to design his work for the painter, than I would to finish his picture for him—however much I could see it wanted it. The more the painter does without "outside help" the better. The better for his picture, himself, and pictorial honesty and morality. That a vast quantity of valuable property of this kind is appropriated is certain, but this kind of flat burglary is becoming more dangerous daily, particularly when the delinquent takes Oliver Cromwell's advice, and copies "warts and all" on the tiger's nose. Then the copyist gives himself away, and, if there is a Gambier Bolton about, he who "takes what isn't his'n" is found out and has to pay.

H. P. Robinson.

BY THE WAY.

The past month has undoubtedly been one of excitement in photographic matters, owing chiefly to the publication of Professor Röntgen's remarkable discovery of the so-called photographic action of certain rays whose nature it is, up to the present time, impossible to classify with any certainty. It seems absurd, however, to describe as photographic an action that goes on in absolute darkness and is produced by rays that are quite invisible to the eye, and which, moreover, appears to set at defiance all the laws that govern the action of ordinary light. Whatever may be the true nature of the manifestations so far obtained, there can be even now little doubt on the subject of the ultimate value of the new power in various directions; and, whether or not subsequent researches prove the X rays to be subject to the ordinary laws of reflection and refraction, it seems that already, in the present crude condition of our knowledge of the subject, there is a wide field open for experiment.

It is true the investigation of such questions as this is confined to few hands; but this is perhaps not a misfortune, but otherwise, since those who possess or have access to the needful scientific appliances are just those who are individually, both by training and by instinct, capable of accurate judgment in investigations of this character. The amateur *pur et simple*, using the term in its highest and best signification, is a useful, and maybe a valuable, assistant in some directions; but in matters of pure science, involving, as does this, the careful weighing and comparison of facts, theories, and hypotheses, it is better that the work should be left to thoroughly trained minds and skilled hands. It is, at least, satisfactory to know that, young as is the new science, there are already so many competent workers not only able but willing to devote their energies to its investigation; and, though the outcome of it all may possess little practical usefulness to the ordinary photographer, we cannot but, one and all, look on with the greatest interest at the gradual development of this, the latest of modern scientific wonders.

Turning from Professor Röntgen's discovery, we come to Professor Herkomer's invention, if such a term can be applied to anything appertaining to art, for, be it noted, the title of "New Art" is claimed for this latest method of engraving, though how one who has proved himself so bitter an enemy of photography and kindred or cognate methods of reproduction can consistently claim such a title for so mechanical a method is rather a puzzle.

We have not to consider in this connexion the broad question as to whether photography is or is not an art, or only a mere mechanical process, but the narrower one, whether a picture by Professor Herkomer's "New Art" is any more an artistic production than a photogravure or other photographic reproduction direct from the work of an artist. So far as I am personally concerned, I should answer, without any hesitation, in the negative, and I should go further and say that the photographic rendering would, in ninety-nine cases out of a hundred, be superior to the "autographic."

Professor Herkomer's idea appears to be that because, to descend to mere technical terms, the "resist" is applied to the metal plate by the discriminating brush of an artist instead of being uniformly spread in the form of a varnish to be afterwards cut through with the graver or etching needle, or, on the other hand, by photographic means, that the result must possess greater artistic claims. But he quite overlooks the fact that the work of the artist ceases with the transference of the idea to canvas, paper, metal, or whatever basis may be selected for its translation into graphic form; indeed the artist may be said to complete his task with the inception of the idea, and the mechanician then commences, be he painter, engraver, etcher, or *photographer*. It does not seem to matter much from an art point of view whether, in the case of an engraving or an etching as it reaches the public, the "artist" does his work, including the mechanical portion that is inseparable from it, upon the canvas or upon the metal plate, with the brush, the etching needle, or with "bits of wood and the finger tips;" but, from the point of view of quality of result, it does most certainly appear as if a better result would, or should, accrue from a proper division of the labour, leaving to the artist the conception and rendering of the subject in whatever medium suits him best, and to the engraver or etcher the task of translating it into suitable "diffusible" form in the best manner possible.

But Professor Herkomer's claim is that by his method the artist is enabled to "reach the masses with his autographic touch," or, in other words, is enabled to do without the aid of photography what photography is so well known in this direction to be capable of doing, namely, to faithfully reproduce the original without losing or destroying the idiosyncrasies of the individual artist, a task so difficult to the ordinary engraver or etcher. But, then, Professor Herkomer abominates photography in any form, but "process" in particular, because it renders art "diffusible" at a cheap rate, or comparatively cheap; and even Professor Herkomer recognises the advantage to the artist of "diffusibility," or, in other words, he knows that the reproduction in popular form and at popular prices adds materially to the pecuniary value of the artist's work, and this branch of the work he wishes to keep in his own hands.

But, it may be asked, is such a method as that of Professor Herkomer's likely to preserve the "autographic touch," the individuality of the artist, any better than would be done by the average engraver or etcher, or half as well as by photography? I think not, more especially if we take into account the fact that the artist becomes his own engraver, and takes up a task for which he has had no special training; for it must be borne in mind that Professor Herkomer lays stress on the fact that, in working his process, the artist has "no new technicalities to acquire, technicalities that have hindered many an artist from taking to plate work." Evidently, then, the "new art" is regarded by its author as not only "autographic," but also "automatic," as requiring neither skill nor brains in carrying it out, so far as the mechanical portions are concerned.

Many photographers will be perhaps better able than Professor Herkomer himself to judge how far the ordinary artist, devoid of technical training, will be likely to succeed with this combination of moulding and electrotyping; for, much as the Professor detests photography, he is not above taking a few hints from its methods. Thus his new "autographic method" of forming a printing surface looks very like a combination of the "dusting-on" process, Colonel Waterhouse's process of photogravure and electrotype; and, though each of these three processes requires for its individual working a considerable amount of knowledge and manipulative skill, their combination is to present no difficulties to the artist who is able to transfer his ideas in a "thick black pigment resembling printer's ink" to a silvered copper plate. The artist by this means is to be able to reach the public direct with his own "autographic touch" unsullied, and, above all, though it is not specifically mentioned,

"scoop in the coin" without the interference of any middleman in the shape of the engraver or photographer. We shall see.

I read in last week's JOURNAL a brief notice of the death of Professor Henry J. Newton of New York, who, some fifteen to twenty years ago, figured very prominently in the amateur photographic world of America. On the principle of *De mortuis* &c., I should be loth indeed, to write anything derogatory of one who in his lifetime was an ardent and enthusiastic worker in the interests of photography; but the absurd, though well-intentioned, claims made by his "obituarist" if allowed to pass unchallenged into "history" in the columns of THE BRITISH JOURNAL OF PHOTOGRAPHY, of all places, would lead to bring ridicule, rather than honour, to his memory.

Amongst other things it is stated, on the authority of the *Scientific American*, that the late Mr. H. J. Newton "recommended the use of nitrate of ammonia in the silver bath for the sensitising of albumen paper, by which the need of preliminary fuming with ammonia is avoided." So far as I recollect, Mr. Newton's name was little, if at all, known in connexion with photography previous to twenty years or so ago, but the introduction of nitrate of ammonia into the silver bath was made by Marlow in 1860 or 1861. Its use was to enable a bath weaker in silver to be employed, and the same end was later arrived at in the States by ammonia fuming. If Newton rediscovered the fact that the nitrate might replace fuming, it does not alter the fact of Marlow's earlier publication.

Then, again, he is stated, in 1876–7, to have improved the collodio-bromide process and prepared an emulsion as quick as wet plates. About that date he certainly published a formula brimful of fanciful variations, most of which, if not direct complications, were at least of doubtful value. But the essential features of the process to which it owed any qualities of rapidity it might possess had all been published previously by his countryman, Carey Lea, and others; and as a process his formula proved a dead failure on this side of the water.

Next, he is stated to have suggested the use of the fixed alkalies in place of ammonia in development; but here, again, Major Russell, in the early "sixties," and later, about 1867, the late Thomas Sutton had forestalled him by at least ten years. Finally, he is said to have "advised the use of yellow prussiate of potash in the developer, and the single solution iodide of mercury intensified for gelatine plates." The first of these was introduced by A. L. Henderson in 1879, and the second by B. J. Edwards about the same time, a period at which gelatine plates could scarcely be said to have established a footing in America. If, later on, the Society of Amateur Photographers of New York, on Mr. Newton's advice, included ferro-prussiate of potash in their "Standard" developing formula, as I believe was the case, it does not deprive Mr. A. L. Henderson of the original credit of its introduction, and the same remark applies to the mercurial intensifier.

I repeat I should be loth to attempt to deprive a deceased experimentalist of any credit due to him; but I do not believe that, in this instance, Mr. Newton would have laid claim in any one case to being the introducer of any of the novelties mentioned. The paragraph is only a glaring instance of the want of care exhibited by well-meaning individuals in their endeavour to say the most they can for a dead friend.

DOGBERRY.

UNDER WHAT CONDITIONS ARE SILVER PRINTS LIABLE TO FADE?

[Society of Amateur Photographers of New York.]

PHOTOGRAPHIC printing made a step backward by readopting the "combined bath." The past history of this objectionable method was such as to guard anybody against its reintroduction. The combined-bath method is undoubtedly very attractive to the confiding user of it. It is simple and quick, and can be used with advantage whenever the lasting qualities of the prints made by it have not to be taken into consideration. The danger lies, not in the method itself, as long as those who use it know what they can expect in regard to permanent results. No, the harm has been done specially by those who should have made every possible effort to tell the truth in this matter. Manufacturers of photographic papers, by recklessly or ignorantly recommending combined baths with their products, have aided very much to give their own articles of manufacture a very bad reputation for fickleness. If albumen paper has still many faithful followers, this is mostly due to the fact that this paper at least has not been abused and tortured with combined baths.

Many have been the discussions on this subject, but I am glad to state that now there is a decided change of opinion in favour of separate baths. However, we meet often with very contradictory assertions yet. Most of the combined-bath advocates will tell you that most of the combined baths are not reliable, but that they have their own formula on which you can safely depend. As proof they will show you prints which have kept well for years. They will explain all the failures by exhausted baths, wrong temperature, imperfect washing, impure chemicals, &c. Let me say right here that such assertions are merely based on illusions. If some combined-bath prints have kept well, this in itself is not a proof of permanency. It is merely a proof that they have not faded, and this may have been due to the fact that they have not been subjected to such strong influences as to change them. In other terms, the question is not, "Will this or that print fade?" but "Are they liable to fade, and in how far are they liable to do so?"

In the actual condition of affairs a photographer turns out every day a certain number of prints, and has to rely on his own guessing or on hearsay when it comes to the question of the permanency of his products.

There was a time when bridges, buildings, and machinery were constructed without much accurate knowledge of the resisting strength of material. Each undertaking of the kind was an experiment in itself. The builder was taking the alternative of either wasting material by making his construction unnecessarily heavy, or of finding afterwards that the results of his work were unsatisfactory in regard to strength.

Modern industry is no longer satisfied with this, and wants more accurate information. Modern engineers have their materials carefully tested, chemically and physically, and this enables them to obtain the most reliable results in the most favourable conditions.

In the manufacture of guns, armour plates, bicycles, &c., testing has become an important factor, and has helped enormously to develop and perfect these industries. Bicycle-manufacturers, for instance, do not decide on the quality of their machines by idle words, but by substantial tests. They do not admit, as proof that a machine of inferior make is as good as one of their own, the fact that one has lasted as long as the other, because neither of them may have been subjected to work serious enough to decide the question of quality.

Why should not the same methods be adopted in determining how far photographic prints are liable to fade? Let us see now what are the most appropriate tests which will give us an idea of the relative permanency of silver prints. A popular test among photographers is to subject the print to the action of strong sunlight for several days. If there is no change in colour, this is considered a proof of permanency. This test is very incomplete and superficial, and has led to many errors. I have seen combined-bath prints behave very well in sunlight, yet they faded badly when kept in an album or in a closed box. Furthermore, it is a known fact that pure, uncoated paper, bearing neither image nor silver emulsion, will turn in colour when subjected to the action of sunlight. The most expensive and best white paper, such as that used for platinum or bromide paper, will change in colour if submitted to sunlight during a few days.

Baryta-coated papers will change just as quickly under the same conditions, and, as they are always slightly tinted pink or *pensé*, their tint will be somewhat greenish. I have seen some of such papers change after one hour's exposure to the sun. By the results of such tests which I show you here, you can judge yourselves as to the extent of the change in colour. You will notice that some kinds of writing-papers, and particularly newspapers, become dark yellow when exposed to the sun for several days. These changes in the tint of the paper should not be mistaken for the fading of the print. The latter is caused by a thorough transformation of the silver image under the influence of chemical agencies. In order to study the cause of such fading, let us examine briefly the nature of the silver print itself, and let us enumerate what are the possible influences that can affect it. The early chemists classed silver together with gold and platinum amongst the noble metals, in opposition to the non-noble or base metals, which are lead, copper, iron, nickel, zinc, &c. This distinction was chiefly based on the fact that noble metals withstand direct oxidation, and that most of the chemicals have little or no action on them, while base metals are easily oxidised and affected by most chemical agents. Gold and platinum will not be affected by any of the regular constituents of the atmosphere, and that is the reason why these two metals remain perfectly bright and untarnished. More than that, it is well known that gold coins which have been kept

under favourable conditions for thousands of years have retained all their lustre. Silver would behave just as well as gold and platinum, were it not for the fact that it has a great affinity for sulphur, and will combine readily with this latter element whenever it has a chance, and this is the reason why silver is liable to tarnish. The slightest trace of hydrogen-sulphide (sulphuretted hydrogen) in the air will cover it very soon with a very thin, yellowish film of silver sulphide, which will become brown, then finally turn black. Here is a bright silver dollar piece, and you observe that, as soon as I bring it into this bottle in which I have produced some hydrogen sulphide, it becomes covered with a black deposit of sulphide of silver. DR. LEO BAEKELAND.

(*To be continued.*)

PHOTOGRAVURE.

BEFORE the Brixton and Clapham Camera Club, on January 21, a demonstration of Photogravure was given by Mr. A. Ernest Smith (Ealing P. S.), chief of the Autotype Company's Photogravure department, and winner of the Society of Arts prize for Photogravure. The demonstration attracted a very large attendance to the meeting, the chair being taken at eight o'clock by Mr. W. Thomas (Vice-President). The following is Mr. Smith's description of the process :—

"Before commencing my demonstration of Photogravure this evening, I must at once say that to tell you all I should like to on the subject would take me quite six such evenings. The time allotted me for this demonstration is barely sufficient to give you an outline of the process. I shall endeavour to make it as interesting as I can. When I gave my demonstration on photogravure before the Ealing P.S. I spoke of the negative, the positive, plate, resist, &c., under their different heads, and answered questions on each head before I proceeded with the next. By this means I managed to make myself pretty clearly understood, and we had quite a chatty and interesting evening. I shall therefore be glad if you will ask any question relating to the various headings as I proceed, and I will do my best to answer you. Then we can go on to the next heading. I have come over from Ealing to try and interest you, and, if possible, to help any of you here who may have already dabbled in the process. I shall, from time to time, hand you round the various articles used in the process of photogravure, many of which will explain themselves, and give you a far better insight of the process than any amount of talking. So much for preface, and now to business.

NEGATIVE.

Like most other photographic processes in photogravure, you want, to begin with, a good negative if you wish to obtain the very best result. These negatives handed round to you have all had photogravures made from them, and will show you the quality required perhaps better than I can tell you. I may say, commercially, we have to get used to making photogravures from all sorts and conditions of negatives, both amateurs, and professionals, (some of them very queer ones). A negative that will yield a good, soft, albumenised, silver print is the very thing for photogravure, at least so I have found, and I have worked photogravure processes for the Autotype Company, or been directly connected with them, for ten years. I may say here that I am an engraver, and I always, in reproducing a painting, work from an engraver's point of view, and not a photographer's. I have here the negative which I took at South Kensington, of Mulready's picture, *Choosing the Wedding Gown*. I tried various plates, but finally got this result on an Autotype plate, which was one of a batch specially made for me, and it was this negative which helped so much towards getting the photogravure with which I carried off the Society of Arts medal. I will not pass it round, but you can see it afterwards.

When you have got a suitable negative, take out any transparent spots and do any necessary retouching to it. Place a *safe edge* round the subject, either of orange paper or Bates' black varnish, as you see on the negatives handed round. When this is done, we can proceed with the transparency.

TRANSPARENCY.

The next step is to obtain a positive or transparency. I prefer the carbon transparency for all-round work; and, as most negatives are taken direct (*i.e.*, without the use of a mirror), a carbon transparency brings the image on the glass the right way about, I mean as regards right and left. For this process the film side of the transparency should be reversed as compared with the original, or just as it is in the negative. The transparency may be made so reversed on a dry plate in the camera or by contact on a stripping plate, but the carbon transparency does away with a lot of unnecessary bother. I will now hand round a few transparencies which have been used for photogravure. I see from your programme that Mr. Archer gave you a demonstration in carbon printing recently. I am heartily obliged to him, for by so doing he has somewhat paved the way for me, as I have very little time to spend on this part of the subject. To obtain a carbon transparency, you take a piece of the Autotype Company's transparency tissue, and expose it behind a negative to daylight, in a strong printing frame, for the requisite time. The exposure is judged by the use of an actinometer. This one I have used for years (a Johnson's). Experience will teach you just how many tints to expose it. If you have already used your negative in carbon printing and know just how many tints you gave it to get your paper print, all you have to do is to give it three times as much, or perhaps a little more, and you will not be far from the mark. It must be understood that this picture on glass is to be viewed by transmitted light and not by reflected light, hence the much longer exposure. When the tissue has been exposed sufficiently, it is taken out of the printing frame and placed in clean cold water, together with the glass on which it is to be developed (this glass having already been coated with bichromated gelatine and rendered insoluble by exposure to light). When the tissue has uncurled itself outwards and shows a tendency to lie flat, bring it (don't wait too long) into contact, under water, with the *coated* side of the glass plate, lift out carefully on to any flat surface, and squeegee the tissue firmly on to the glass. It is then laid on one side, either reared up on one end after getting rid of the superfluous water, or laid between bibulous boards or blotting-paper for, say, ten minutes (half an hour won't hurt it). It is then placed in hottish water, stripped of its paper support and developed just as you would a paper print, by laving it with the hand or rocking it about in a small bath. After the soluble gelatine has been got rid of, it is laid in clear cold water to set and afterwards put on one side to dry. A safe edge is then put round the transparency, as in the negative, and we are ready for printing the resist. A transparency that is too flat may be improved by soaking a few minutes in a very dilute solution of permanganate of potassium, this having a straining action on the film which improves the transparency to an extent greater than is indicated by appearances.

RESIST.

The *resist* is the technical term given to the gelatine *negative* film which we have to develop on the copper plate and through which we are to etch. This is best obtained by exposing a piece of either of the Autotype Company's etching tissues behind the carbon transparency already made, for the required number of tints on the actinometer. The transparencies handed round have a note of the various tints they require on their margins. Before taking the etching tissue out of the printing frame, it is as well to mark the back just to show in what position to place it on the copper plate.

COPPER PLATE.

Now about the copper plate. I have here a piece of copper which is a fair sample; it is fairly hard, and I think you can get capital quality for photogravure at about 2*s.* to 2*s.* 6*d.* per lb. It should be well polished; either up and down the plate, or, in what is termed, the circular fashion. It must be free from scratches and holes, as these would hold ink and damage the lights of the picture. A great deal has been said about the quality of the copper, and a great deal of blame laid at its door of which I am sure it is perfectly innocent. Something has to bear the blame; sometimes it is the copper, at other times the tissue, then the negative is not suitable, &c. It is *never* the operator who is in fault. When you have your copper plate, the first thing to do is to clean it. Free it from grease and tarnish. To do this, make up a paste of finely washed whiting and water, and add a few drops of ammonia to it. Some of this paste is taken on a tuft of cotton-wool, and rubbed over the plate in a *circular manner*. This may have to be repeated if the plate is very dirty. If the surface of the plate repels the water, you may rest assured it is still greasy. When the water clings to the plate all over, it will do, there is not much grease left. Then take off any tarnish with very dilute nitric acid, wash in water, and dry with a *clean* rag. The plate is then ready to receive the grain.

GRAINING THE PLATE.

We will suppose that a copper plate about 7 × 5 requires graining. A wooden box about 18 inches cube is a good size for that plate, or, say, 18 inches wide, 24 inches long, and 18 inches deep. The box should always be much larger than the plate to be dusted, to ensure an even layer of dust. Into a box of, say, 18 inches cube, I should put ½ to ¾ lb. of finely powdered bitumen. This can be procured already ground. In lump it is black, like pitch; but, when powdered, it is brown in colour, and, when *very* finely powdered, it has quite the colour and appearance of snuff. I generally give the powdered bitumen as bought an extra rub in a mortar, and always judge of its fineness by its colour.

Small boxes are shaken up in the hands to create a perfect smother of dust inside. Large boxes are revolved after the manner of a churn, and some very large ones have an arrangement for blowing up the dust from the bottom, whilst the box is stationary. The method of graining is as follows: The drawer is taken out of the box, and the plate to be grained is laid upon it within easy reach. The lid is put into its place, and the box is then shaken up well, say, eight or ten times, resting occasionally to give it a tap on the top and sides. (In the larger boxes which revolve you keep tapping them all round as it is slowly revolving.) This keeps the dust from clinging to the sides. After a good shake up, the box is placed on the table, and a sharp rap or two given to the top to remove any lumps that may have collected there. When this is done, rest for, say, forty-five seconds or a minute to allow the larger particles of dust to fall, and insert the drawer on which your plate is lying. Let it stay in the box, say, three minutes. At the end of that time take it out carefully, and *fix* the grain to the plate by heating it over a Bunsen burner until the brown dust changes to a "bluish" bloom all over the plate. Do not over-heat the plate, or you will have what is equivalent to a coarse, open grain. If you do not heat the plate sufficiently, I need hardly say the dust could be wiped off when cool. Some subjects require a very fine grain, others quite coarse. After a little practice you will soon be able to make up your mind as to quantity of dust. The grained plate I am handing you round has a good medium dust on it, and, if you will hold it horizontally from you towards the light, you will see the bloom over the surface. I need hardly tell you that, if you want a finer grain, you have only to make a longer rest, after shaking up the box and before putting in the plate. If you want it coarse, put the plate in as quickly as possible after it has come to a standstill, and let it remain three and a half minutes. This will give you a grain that will allow you to etch for thirty minutes without its being bitten away. The question I have often had put me is, Why need the plate be grained? I have a little plate and proof here that will speak pretty well for itself. The plate you see has been filled in with ink, and wiped off ready for printing. You will see that the ink wipes out on the ungrained side, whilst on the other it is held in its various depths by the grain. It is the bitumen dust fixed firmly on the surface which resists the etching fluids, and so, by breaking up the surface of the etched portions, gives us what we call its ink-holding property. Some workers of the process prefer resin to grain their plates with, whilst others use a mixture of resin and bitumen.

Developing the Resist.

The plate is now ready for the resist, which I have already mentioned. This is developed on the plate in exactly the same manner as the transparency was developed on the glass. The plate and tissue are laid in clean cold water until the tissue begins to uncurl itself; it is then brought into contact under water with the plate, taking care to get it as square as possible, which you can judge by the marks on the back of the tissue. The plate, with the tissue, is then lifted out and squeegeed together, not too roughly, or the grain may damage the resist and cause trouble afterwards. Rear the plate up to rest for, say, ten minutes after blotting off most of the water. It is a good plan to fan it at this stage, and helps it a great deal. It must not be warmed, but kept as cool as possible. Take the plate after its ten minutes' rest and lay it in hot water (about 100° Fahr.) until the colour begins to ooze out round the edges, lift off the paper support, and develop until all the soluble gelatine is washed away. Make sure of this by leaving it in hotter water for five minutes or so after it is apparently developed, then take it out and lay it in cold water for a minute to set. Rinse it under the cold water tap and rear it up to dry, letting the lower end rest on some clean blotting-paper. When the resist is quite dry, the copper margin and back are protected with Brunswick black or Bates' black varnish, and the plate is ready for etching. The straight edge round the subject is first got with a ruling pen charged with Bates' varnish, the margin is then carefully covered with a brush. Any transparent specks of copper showing through the resist must be carefully spotted out with the black varnish, or a deep hole will be etched in the plate, and, if this occurs in a face or sky, the plate will be ruined.

Making up the Baths.

The baths used for etching through the resist are different strengths of perchloride of iron. To prepare them, get a quantity of perchloride of iron, and add about one-third of its bulk of water, or even less, and stir up well, so as to dissolve as much perchloride as possible. Pour some of the liquid obtained into a testing glass, and test its strength with a Beaumé's hydrometer. You will probably find that the liquid registers 45° to 47° Beaumé. You will then be able to mix up the different baths as follows:—

No. 1	43° Beaumé.
No. 2	40° ,,
No. 3	38° ,,
No. 4	36° ,,
No. 5	34° ,,
No. 6	32° ,,
No. 7	30° ,,

The baths must not have too much free acid in them, or blemishes are likely to arise in the etching. A little hydrate of iron placed in each bottle of solution takes up some of this acid, and makes the baths work much better. This is a trouble to make, so I should advise you to buy it. These two plates will show you some of the defects got in etching; one I call stars—they also go under the appropriate name of "devils"—and the other "pits."

Etching.

Now, as to the method of etching. You begin first with the strong bath; pour gently over the plate, and avoid air bells. This bath, if it etches at all, will confine itself to the extreme shadows, which are represented on the plate now as almost clean copper. If this bath will not start etching, the resist is slightly over-printed, so try the next (40° Beaumé). Let the extreme blacks of the picture have a bite of two minutes. Then pour off, and go on with the next bath (38° Beaumé), which will etch the next tones, then to 36°, and so on until the etching is finished. This should be completed in from seven to ten minutes for a subject similar to this. Practice and long experience alone can tell you just how long to allow the different baths to remain on the plate, but the rule is to "keep the pot a-boiling." If there is a great tendency for the etching to stick at any of the tones, drop at once to the next bath. This is the most important part of the whole process, and requires a great amount of judgment, which seems to come naturally to you after a long experience. When the etching is completed, the plate is placed at once under the tap and the resist rubbed off. A little whiting and ammonia is then rubbed over the plate to check any further action of the perchloride, and the plate is then cleaned up ready for printing. The black varnish is taken off with turps, and the bitumen grain dissolved off with benzole. The plate is cut square with a circular saw, its margins bevelled with a file, and burnished with charcoal and oil.

For *printing*, the plate is filled in with ink with a cloth dabber, and wiped with canvas; a roller press is used, and considerable pressure applied. For retouching, any slight defects in the plate are used: the roulette (about six to the set), a tool carrying a small wheel with one or more rows of fine points, the point, and the scraper, bayonet-shaped, and mostly used for removing any slight obstructions.

Plates from which a large number of prints are wanted have their surfaces coated with a deposit of iron by electrolysis—the "steel facing."

A. Ernest Smith.

WINTER PHOTOGRAPHY.*

Coming now to the region of practical photography at moderately low temperatures, the well-known scientific photographer, Captain Abney, has something of interest to say.

In an article in *Photography* for April 18, 1895, Captain Abney, after referring to the work of Professor Dewar, says: "The writer has, however, taken up his original investigations of the amount of chemical action which takes place in those temperatures in which the photographer may be called upon to work, such as that of this last early spring, and of a hot summer, these temperatures not falling especially into the work which Professor Dewar has set himself to carry out. The main facts brought out by time and intensity exposures at these more moderate temperatures seem to be these: first, that plates vary in sensitiveness when exposed at a high temperature and at an ordinary low temperature. A slow plate seems to vary more than a quick one, thus a slow lantern plate seems to require about $2\frac{3}{5}$ times the exposures at 0° F. that it does at 100° F., whilst a very rapid plate only requires about $1\frac{4}{5}$ times, that is, the latter plate is about $\frac{1}{3}$ better than a slow plate. The difference of exposure required between a lantern plate exposed at about 50° F. and 100° F. seems to be about half as much again. This may not be a serious matter for the landscape photographer, as it is probable that there is such a latitude in his plates that it would allow this difference in time to pass almost unnoticed."

The above opinions and results of experiments, as before mentioned, agree with my limited experience, that the effect of temperature on the sensitiveness of fairly rapid plates may in practical working be disregarded, especially if one considers how very few photographers can be

* Concluded from page 73.

certain of correct, or so-called correct exposures, when it becomes a question of fractions of a second.

Practically, then, exposure depends on the light present, the same as at any other time of the year, and must vary somewhat with the amount of contrast in the subject. I find that from one and a half times up to double the exposure that would be given to the same view in summer time will be ample, and I invariably treat a plate exposed on a bright winter subject as being over-exposed.

To my mind a much more serious difficulty occurs when the photographer comes to develop his plates. This point will be presently considered.

At this stage, perhaps, a few words on the choice of subject may not be amiss, although I make no pretence to knowledge or ability in this direction. One thing, however, seems quite clear, and that is, that many a scene or subject, which would be quite commonplace, even with the cleverest handling, in summer time, may be found in winter to be well worth a photographer's best efforts. Of course, the question of point of view, selection of foreground, and amount of subject to be included remain, as at other times, a matter of individual taste. However, the treatment of snow or ice under bright sunshine presents some pitfalls, which may, perhaps, be indicated with advantage.

It will be found, under such conditions, to be almost impossible—with me it has been quite impossible—to correctly render large and comparatively flat areas of snow or ice surfaces if the camera be pointed either directly towards the light or in the opposite direction. In the first case, a line of the most brilliant sparkle or glitter will be presented, in contrast with other objects, such as the trunks of trees, &c., in deep shadow. To correctly render both becomes practically impossible.

In the case of the sun behind the camera, the flat surfaces seem to lose their snowy texture, and present a glaring white mass. This, however, may be somewhat improved by trampling a path through the snow, taking care to make the path curve or lead in a direction that will harmonise with the general idea of the subject.

On the whole, I think that the best rendering of such scenes will be obtained when the sun is more or less at right angles with the direction of the camera. With diffused light and in hazy weather, these difficulties almost disappear.

On the other hand, the treatment of rugged masses or piles of ice or snow in the foreground appears to afford greater latitude, and, in fact, may be perfectly rendered with the light coming in any direction.

To my mind, however, bright sunshine in front of the camera, which is such an obstacle with flat surfaces, becomes quite charming with rugged masses, lighting up their outlines brilliantly and giving them a very pronounced character. Whilst the foregoing remarks deal only with certain clearly defined winter subjects, it must not be forgotten that many other delightful wintry scenes may be met with, which will call for individual judgment and decision.

I think it will be conceded, by those who have given it a fair trial, that the development of plates during very cold weather is the most critical period in the production of a winter picture. Personally, I am quite satisfied that cold solutions, dishes, and atmosphere in the developing room are responsible for a great deal of the apparent slowness of plates, or supposed under-exposure than any previous action of low temperature.

It has been frequently pointed out, and is easy to demonstrate, the fact that a very cold solution will retard development. Now, this retarding action is a most undesirable one in the case of winter exposures, since under normal conditions the time of development has to be somewhat long in order to obtain the best results from an exposure on a subject having extremes of light and shade. This latter has been pointed out by Captain Abney, who long since published his method of developing exposures on Alpine scenery.

Before learning of his method of development, I had made numerous failures, and settled down to my own way of working; this, curiously, is exactly the opposite of what he finds best. If I remember rightly, he (and other workers too) recommend that a very thin image, full of all possible detail, be first coaxed out by means of a very weak and dilute developer—then follow with a normal solution to secure density. I, on the contrary, have succeeded best by applying a strong but very restrained solution until satisfied that the high lights were almost sufficiently dense, then washing and applying a very dilute developer until all detail was out. Probably Captain Abney's method is the most reliable, but in any case it will be noted that the time required to get a satisfactory result is longer than with almost any other subject. This fact introduces the human element, and one which, to my thinking, decides whether the result will be a success or not. It will be obvious that, unless the worker is carrying on his operations in a comfortable temperature, there will be a natural tendency to shorten or hasten development, which is fatal to good results with winter scenes.

Evidently, then, development should take place in a room thoroughly warmed, and, if the usual dark room does not permit of this being done, operations should be postponed until the evening, when either the dining-room or kitchen may be requisitioned. I have often worked in a room in which a bright fire was burning, by taking the precaution to screen off the direct rays of light and the reflections from the ceiling. It is, of course, wise to keep the developing dishes constantly covered, except during the brief intervals when the negative is lifted out for examination. I find that from 45° to 50° Fahr. is a suitable temperature for solutions. In order to maintain them fairly constant when compelled to work in a cold room, I generally use a large tray about half-full of tepid water, in which the developing dishes are placed; then, by adding a little hot water from time to time, from a jug kept handy, the temperature of the water in the large tray and the developing solutions can be kept up.

The precautions to be taken to prevent negatives from being frozen during washing and drying are self-evident, yet it may be mentioned that steps should be taken to avoid such an occurrence, as it would otherwise mean the utter ruin of a negative.

The next process, viz., that of printing winter scenes, is probably one that affords the largest scope for individual taste and opinion. I have tried a fairly large range of ordinary printing processes—in fact, all, I think, except carbon—and I am by no means disposed to agree with those who think that a black-and-white is essential for a correct rendering of winter scenes. Neither am I quite satisfied with my own attempts to secure a proper representation with sepia, platinum, or plain silver paper toned with gold to a purple or bluish colour, although I think the latter nearer to nature than the warmer colour. At the present moment I am inclined to think that a small amount of pure white high light and a good gradation of grey down to strong grey in the deepest shadow to be the most satisfactory. This appears to be difficult of attainment with platinum, except with thin negatives.

Ordinary bromide paper also presents the same difficulties, although in a lesser degree, as the blackness in the shadows may be much modified by a variation of exposure and development, also by alterations in the developing solution itself. I feel convinced that printing papers of different degrees of roughness may be used for different negatives with good results, but on this point I am not prepared to make any suggestion.

This concludes the purely photographic operations intended to be dealt with in this paper, yet the final stage of mounting and framing of such pictures as may be considered worthy is one that calls for the most careful consideration, as even at this point an otherwise charming picture may be killed. For my own part, I feel that no rule can be laid down, and that no shade or style of mount and frame will suit all subjects.

Finally, it is hoped that, if these remarks contain nothing of value, they will at least serve to elicit some useful ideas in the discussion.

G. F. Blackmore.

The Inquirer.

*** *In this column we shall, from time to time, print questions that may be addressed to individual contributors to our pages, or such as are sent to us with the view of eliciting information from a variety of sources. We invite the co-operation of our readers in rendering this feature of the* Journal *useful and instructive.*

Commercial Printing (To Photographer).—A. G. W. says: "Referring to the question in your last week's issue, I beg to say a few words. I say that it is quite possible for any good printer to manage 80 frames and get off 200 prints on a bright day. I, myself, with the aid of another lad, aged seventeen, have done so day after day, and it seems to my idea that by the way in which our friend writes he is either an amateur or of a very weak intellect. I should very much like to correspond with my friend through the medium of your paper."

Acetylene.—G. H. Rodwell writes: "Surely you must have made a mistake when you say, in answer to E. W. B., on p. 73 in last week's Journal, that the amount of acetylene gas obtainable from one pound of calcium carbide should be nearer five hundred than five feet. Taking the reaction as follows:

$$\begin{array}{rcl} C_2C_2+2OH_2 & = & C_2H_2+C_2(HO)_2 \\ (40+24) & = & (24+2) \end{array}$$

therefore 64 grains C_2C_2 give 26 grains of C_2H_2. One pound, therefore, or 7000 grains, will give $\frac{26 \times 7000}{64}$ or 2844 grains of acetylene gas. The molecular volume of acetylene being [ ] it follows that the specific gravity of the gas is 13, taking hydrogen as unity, and is thus slightly lighter than air (13 as to 14·4). Now, 44·4 cubic inches of the gas would weigh 13 grains; therefore the number of cubic inches in 2844 grains would be $\frac{2844 \times 44{\cdot}4}{13}$ or 9713 cubic inches, which gives 5·62 cubic feet as the theoretical maximum obtainable from one pound of calcium carbide, assuming the salt to be chemically pure. In the very excellent article on acetylene, which appeared in the Supplement to your Journal on January 3, Mr. Banks states that a Bray's 0000 burner burns half a foot per hour. My experience does not coincide with this. I have tried three of Bray's smaller burners, respectively numbered 0000, 00,000, and 000,000, and the amount of gas burnt by each are respectively $1\frac{1}{4}$, 1, and $\frac{3}{4}$ feet per hour."

SITUATION IN CHICAGO.—"LILLIAN" says: "Could you kindly give me any information as to how I should obtain a situation in Chicago as first-class retoucher? I have served my time in the best house in Dublin, and have been principal lady retoucher in same firm for past five years. Would it be better to write direct to some of the leading houses there? if so, would it be encroaching on your valuable space to give me their names? What salary do you think I could obtain?"—Possibly some of our readers may be able to help our fair inquirer.

Our Editorial Table.

INDOOR PHOTOGRAPHY AND FLASHLIGHT STUDIES OF CHILD SUBJECTS.

By BEATRIX M. LOTHROP. Bradford: P. Lund & Co.

MISS LOTHROP'S booklet contains reproductions of about twenty-three indoor child studies, of a not particularly good or bad quality, photographically or artistically, although, no doubt, they might be considered pleasing to the feminine taste. The hints given as to the utilisation of the flashlight for this kind of photography are brief; but, as a whole, the booklet is an amateurish production, not the least misleading part of it being the title "Indoor Photography," with which it cannot be said to deal, except cursorily.

THE ELECTRO-PHOTO COMPANY'S SENSITISED ALBUMEN PAPER.

THIS Company, whose address is 30, Fleet-street, have sent us samples of an albumen paper they are just introducing. The paper, judging by the results we obtained on the sample pieces, is an excellent one, giving prints of an admirable "albumen" quality, and possessing all the desirable points of such a paper, such as freedom from blisters, evenness of toning, and a good surface.

THE COMBINATION MEMO-BOOK AND LETTER-CASE.

MESSRS. SHACKELL, EDWARDS, & Co., the well-known printing-ink makers, of Red Lion-passage, Fleet-street, E.C., evidently have a warm corner in their hearts for editors, who are called upon at all sorts of times and seasons to "make a note of" something or the other, for they have sent us one of their improved combination memorandum-books and letter-cases. This is a neat little memo-book, placed inside an elegant leather case, which holds letters, &c. Perhaps the nicest thing we can say of this memo-book is that, ere these lines catch the reader's eye, it will have proved very useful to us.

THE IMPERIAL FLASHLIGHT PLATES.

THE Imperial Dry Plate Company, Cricklewood, have recently sent us some of their newest plates called, not unhappily, the "Flashlight." They are marked with the remarkably high speed No. 342. Conceiving that plates with such an implied abnormal degree of speed should prove of especial service to professional photographers in dull weather, such as the inhabitants of the metropolis have lately experienced, we resolved to subject the plates to trial under conditions approximating to those obtaining in portrait studios. Accordingly our exposures were made in an ordinary room (to wit, the editorial office of our domestic abode), at four o'clock in the afternoon of one of the first days of this month. Employing the lens at an aperture of *f*-8, and giving exposures respectively of one and two seconds, we were surprised to find, on development with hydroquinone and carbonate of soda (the duration of development being ten minutes), that the longer-timed of the plates gave us, all things considered, extremely well-exposed negatives. Unquestionably the "Flashlight" plates are exceedingly fast, and would be found notably so in a properly lighted studio. It is difficult to estimate the increase in the speed of plates that has taken place in recent years; at any rate, we are quite safe in saying that, speaking from our own personal experience, we should not, under circumstances similar to those mentioned above, have looked, six or seven years ago, for the results we obtained on the Flashlight plates.

News and Notes.

ROYAL PHOTOGRAPHIC SOCIETY.—Tuesday, February 11, at eight p.m., Annual General Meeting. *The New Shadow Photography*, experimentally illustrated, by Mr. A. A. Campbell Swinton.

AN interesting and highly successful competition was lately started in connexion with *Little Folks* magazine. Prizes were offered for the best imaginative drawing of "The Editor of *Little Folks*," and some of the results, together with a portrait of the Editor (from a photograph—and quite as curious as any of the specimens sent in by competitors) will be reproduced in the February number of the magazine.

THE PHOTOGRAPHIC CLUB.—The Annual Lantern and Musical Entertainment (Ladies' Night), under the direction of Mr. F. A. Bridge, will be held in the Club-room at Anderton's Hotel, Fleet-street, E.C., at eight o'clock on Wednesday evening, February 12. Among the attractions will be an exhibition of pictures in his kinetic lantern by Mr. Birt Acres. Tickets may be obtained of Mr. Bridge, East Lodge, Dalston-lane.

NOT the least attractive feature of the *Minster Magazine* is a score or more types of beauty, specially drawn by leading black-and-white artists as their own ideals. Among the contributors to this interesting collection are Bernard Partridge, Dudley Hardy, Hal Hurst, L. Raven Hill, Lewis Baumer, Max Cowper, J. W. T. Manuel, Yorick, T. Walter Wilson, R.I., H. R. Millar, Gordon Craig, Sydney Adamson, Rob. Sauber, Fred Pegram, &c.

THE new system of photography has already received official recognition in Germany. The *Reichsanzeiger* publishes the following:—"The Ministry of War, in conjunction with the Imperial Institute of Physiology, has carried out experiments on the application of the Röntgen discovery to war surgery. A series of photographic impressions gave a clear picture of bone injuries, and permitted the position of an embedded projectile to be ascertained with precision. The experiments will be continued on a larger scale."

OPENING OF MR. SWEET'S NEW STUDIO AT ROTHESAY.—The premises in East Princes-street, Rothesay, reconstructed by Mr. Charles Sweet for the purposes of his business, were recently thrown open to public inspection. The whole of the ground floor is utilised as a show-room, with shop frontage to East Princes-street and Bishop-terrace Brae. Specimens of the firm's work are here on view, and in addition there are oil paintings of Provost Milloy, and coloured enlargements of General Macdonald, Mr. Graham Murray, M.P., and others. On the first flat there are five rooms, consisting of lady's dressing-room, gentleman's dressing-room, spare waiting-room, and workroom. These and the show-room are elaborately and artistically furnished and decorated, and on the walls are excellent reproductions of famous paintings by Tadema, Goodman, and Miss Thompson. The top flat forms a spacious operating gallery, with a dark-room and negative-room adjoining, fitted up with the most modern appliances for the successful prosecution of the photographic art. The studio has a north-west light, and the blinds—a most important feature in connexion with the manipulation of the light—are worked on the new carriage system. Cameras, backgrounds, accessories, and furniture are of the most up-to-date type; and the establishment, taken all over, is perhaps the most modern and best equipped on the West Coast. The general arrangement and the skilful manner in which every available inch of space is utilised reflect great credit on the architect, Mr. A. M. Mackinlay.

THE X RAYS.—"German men of science," says the *Standard*, "are now busy investigating the nature of the rays discovered by Professor Röntgen, and, among other things, are searching for means of shortening the long interval of exposure at present required to procure the new photographs. Professor Gieseler, of Bonn, has been experimenting with the view to utilising the fluorescent effects of Röntgen's rays to this end. He smeared a piece of paper with various substances, laid it on the dry plate, and exposed it to the rays. He has already found that chloride of iron, nitrate of uranium, and extract of cuba wood have the desired effect. He then steeped the dry plate itself in chloride of iron, and thus succeeded in further abbreviating the process. Systematic experimenting in this manner, he thinks, will be the best way of finding the fittest substances for expediting the process. Professor Gieseler also points out that ordinary rays are just as little broken by the eyes of insects as are Röntgen's rays in the new photography, and he suggests that, as the eyes of insects can very easily be artificially imitated, such imitations may, perhaps, prove of use in the production of sharper outlines in the objects photographed by the new rays. A member of the Photographic Club at Crefeld has found that the time of exposure is shortened exactly by one-half by heating the plate. He heated it up to about 40° Cent. (or a 104° Fahr.), and the process then occupies only fifteen instead of thirty minutes. This effect, it is conjectured, is probably due to the enhancement of the fluorescence by heating, and cannot fail to be of great use in the case of small apparatus. Professor Goldstein, of the Royal Observatory here, in a recent lecture on cathode rays and Röntgen rays, pointed out that cosmic physics have already obtained very valuable new results by the study of the former. Some of the results of observations of the sun's surface, which were a mystery before, are now explained by the discovery of the fact that the cathode rays propagate electricity from body to body in certain external circumstances under which such propagation does not otherwise take place. He has also proved by experiments that, when these rays strike a second cathode, they are repelled by it. The fact that Röntgen's rays are not deflected by magnets is adduced by Röntgen as a proof that his rays are quite new. Professor Goldstein, however, objects that there are cathode rays which are likewise not influenced by magnets. The main characteristic of Röntgen's rays, viz, the power of penetrating bodies which are impermeable to ordinary rays, is also shared by several other kinds of rays. M. Raoul Pictet, for example, has proved that rays emanating from very cold bodies penetrate all media, including even layers of wadding up to two metres in thickness. It is also known that ultra-violet rays penetrate plates of vulcanite and thin layers of silver, which common light does not penetrate. In this connexion, Goldstein referred to the observations made by Dr. Cornil, a Paris physician, to the effect that patients who have successfully undergone the operation for cataract can see ultra-violet rays which are invisible to others. According to Professor Goldstein, the common characteristics of cathode rays and Röntgen's rays are rectilinear propagation, the production of shadow photographs, and chemical action. The species of rays to which Röntgen's belong, he thinks, cannot yet be determined, but that there are many grounds for believing that they belong to the cathode species."

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK

February.	Name of Society.	Subject.
10	Ireland	Opening of Exhibition.
10	Richmond	*A Chat on Photographic Chemicals.* G. Ardaseer.
11	Birmingham Photo. Society	Demonstration upon Lantern-slide Making. Hall Edwards, L.R.C.P.
11	Brixton and Clapham	*The Troubles of a Tourist.* R.G.F. Kidson.
11	East London	*Carbon Printing.* Autotype Company.
11	Hackney	Open Night.
11-15	Ireland	Annual Exhibition.
11	Royal Photographic Society	Annual General Meeting.—*The New Shadow Photography.* A. A. Campbell Swinton.
12	Ashton-under-Lyne	Lantern Exhibition: *A Visit to Ireland by Four Members of the Society.*
12	Borough Polytechnic	Bromide Printing by Members.
12	Croydon Camera Club	Sixth Annual Meeting.
12	Leytonstone	*The Evolution of the Eye in relation to Photography.* A. T. Cuffey.
12	Photographic Club	Annual Lantern and Musical Entertainment.
12	Southport	Developing Competition.

14	Croydon Microscopical	Trial Night for Members' Slides.
14	Darwen	*Wanderings with a Camera.* Alfred Read.
14	West London	Discussion on Beginner's Difficulties.
15	Borough Polytechnic	Demonstration by Autocopyist Company.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

JANUARY 30,—Mr. E. Bayston in the chair.

COLOUR OF NEGATIVES.

The discussion of the evening centered on the following question, taken from the box: "What is the influence of the colour of the negative?" It was presumed in the present case to refer to printing.

Mr. BIRT ACRES thought a yellowish negative would give a better result than one of a blue tint. He said he had once published a process for correcting the harshness of negatives, in which he stained the gelatine film itself and not the varnish, as generally done. The stain was effective only where no reduced silver was present in the film, and no action took place where the silver was reduced. It possessed the advantage over stained varnish, which covered the whole of the image, in that it only affected the gelatine. He mentioned that it was known that gelatine combined with silver, and would not take stain.

Mr. R. BECKETT said it had often been recommended to stain a negative developed with an agent giving a blue negative with pyro, when a better printing negative was obtained.

Mr. A. MACKIE considered the colour of the negative had some influence, and referred to the effect of a green glass in printing. He said, however, that the colour of the deposit and the colour of the stain were two very different things.

Mr. W. D. WELFORD asked if anybody would undertake to produce a negative by such agents as amidol, metol, &c., which give a blue image, with a given exposure, equal in printing quality to one developed with pyro and soda, and offered to produce a negative in yellow giving a harder print than could be got from a blue negative. The conditions were that the plates should receive a normal exposure, and that the prints, by which the contest would be decided, were to be in some process tending to hardness, such as gelatino-chloride. He also undertook to get a print from the blue negative equal to that from the yellow, if stained.

The HON. SECRETARY offered to expose two plates under like conditions and hand half of each to both competitors, and Mr. Smith accepted the challenge. The Hon. Secretary drew attention to an article by Liesegang on the relation of the tanning action in development to staining of the film and the alteration of the printing quality of the negative. He also mentioned some experiments by the same author bearing on the relief of the image produced by some developers, in which one corner of a dry plate was dipped in a ten per cent. hypo solution and another in plain water for a similar time, the gelatine in both cases swelling to the same height. The whole was subsequently immersed in water and dried, when that portion dipped in hypo remained higher than the rest.

With reference to the use of sulphite, Mr. MACKIE had for a long time mixed it with both the ammonia and the pyro: but the HON. SECRETARY preferred to keep all the solutions distinct, and always used the same quantity of sulphite with varying quantities of developer.

Touching the addition of hypo to amidol as accelerator, the HON. SECRETARY thought it was merely adding fog to the negative, and Mr. WELFORD said one had no means of regulating its action and no control whatever.

Mr. SMITH said it had been stated that the time of adding the hypo made a difference. It should not be added till after the image has appeared.

PHOTOGRAPHIC CLUB.

JANUARY 29,—Mr. Walter D. Welford in the chair.

Mr. George Hare very kindly presented to the Club the model of a camera front made thirty years since, and which Mr. Foxlee had shown at a previous meeting. This contained the principle of a newly patented camera which had been recently shown to the members, and for which claims of originality had been made and contested by certain members. A vote of thanks was passed to Mr. Hare for his kindness, and the model was added to the Club museum.

The Judges of the Watkins developing competition presented a written report, which will be published *in extenso* by the courtesy of the photographic press, and they were thanked by the meeting for the trouble they had taken.

Mr. HAROLD BAKER, of Birmingham, then gave his lantern lecture upon

THE AVON VALLEY.

In an interesting manner Mr. Baker eulogised the valley of the Avon, of which he succinctly stated that it was difficult to know where to begin to reproduce its beauties, and impossible to know where to leave off. In a facile manner, and with charming illustrations upon the screen, Mr. Baker took his audience through some of the most characteristic scenery. With typical examples of churches, mansions, river views, half-timbered cottages, partly hidden by plum-trees in blossom, interesting archæological details, plans of old abbeys, sketches of fifteenth-century armour, tracings of memorial brasses, and appropriate recitations from Tennyson and Milton. With these, and an easy flow of carefully prepared literary matter, the evening passed only too quickly.

At the close, Mr. FRANK HAES said that the Club had had an exceedingly great treat, and that he, knowing the district, felt sure that he had enjoyed the admirable lecture as well as any. He recommended the district to photographers who desire to make pictures, and asked for a very hearty vote of thanks for Mr. Baker.

Mr. F. A. BRIDGE seconded the resolution, and the meeting passed the vote by acclamation.

Mr. BAKER suitably responded, and said that he had already spent his spare time during the last three years upon the work, and that he hoped to add to his collection.

Mr. SNOWDEN WARD then showed a few of the new

RÖNTGEN SILHOUETTES,

which were of considerable interest. He pointed out that in places where metal discs had been used to stop the X rays, there were overlapping circles of halation, which he believed to be due to induced electrical action between the pieces of metal; in proof of this he showed one negative in which what clearly appeared to be sparks were represented as passing between two pieces of metal laid upon the outside of the slide in the customary way in which these photographs are obtained. The sparkings looked almost exactly like photographs of lightning.

Mr. BRIDGE stated that Mr. Child Bayley had promised to show at an early date at the Photographic Club some of Mr. Gifford's results, and also the outcome of some experiments which he himself was making.

Mr. R. P. DRAGE then drew attention to the fact that this was the last meeting at which Mr. James A. Sinclair would be present in his official capacity as Hon. Secretary of the Photographic Club. Mr. Drage made a few kindly remarks referring to his (Mr. Sinclair's) great activity in the Club's interests, his courtesy to the members, and to the success which had attended his efforts to provide the Club with good photographic pabulum, and lastly to the improved attendance which had been the result of these efforts. He asked all the members present to unite in a very hearty vote of thanks to Mr. Sinclair.

The resolution was felt to require no formal seconding, every member present testifying his sincere admiration of the way in which Mr. Sinclair had carried out the duties of his office by hearty and spontaneous applause.

Mr. SINCLAIR modestly replied, and the meeting closed.

MANCHESTER PHOTOGRAPHIC SOCIETY.

JANUARY 22.—Mr. A. E. Casson introduced the subject of

STEREOSCOPY ON THE SCREEN.

Two lanterns are used, either side by side or a biunial, with lenses of as equal focus as possible. A stereoscopic transparency is cut, and one half placed in each lantern. Behind one is a piece of red glass; behind the other green glass. The two pictures are projected together on to the screen, the result being an indistinct mass of colour, caused by the two slides occupying the same place on the screen. The pictures are then looked at through coloured spectacles having red and green glasses, the result being that both pictures blend as one, and stand out in stereoscopic relief. After a description of the principles of stereoscopy by Mr. WHITEFIELD, these were put through the lanterns slides by Mr. Freshwater, of London, and the process did all that is claimed for it. Messrs. Newton & Co. are the publishers of slides and spectacles. This was followed by an exhibition of slides by R. W. Thomas & Co. on their lantern plates, from negatives taken on their anti-halation plates, embracing many of the cathedrals of England, including Winchester, Ely, St. Paul's, and Lincoln.

Brixton and Clapham Camera Club.—January 21, Mr. J. W. Coade (President) in the chair. A paper and demonstration of

ELEMENTARY PHOTO-MICROGRAPHY

was given by Mr. R. G. MASON, who went thoroughly into the subject, and enabled the members to have a most interesting meeting. He concluded by showing through the lantern a number of slides of microscopic objects, including a splendid series, *The Anatomy of a Honey Bee.* A member exhibited a slide of a hand taken by the "new photography" of Professor Röntgen. Mr. W. THOMAS explained how these photographs were obtained, and described experiments in the same direction by Mr. J. W. Gifford. It was decided to open, in the name of the Club, a subscription list in aid of the Traill Taylor Memorial.

Croydon Camera Club.—The Twenty-third Public Lantern Show at the Braithwaite Hall was held with even more than the usual *éclat*, the audience being so large as to necessitate space for a portion being found in the lecture-room attached to the hall. The Club was particularly fortunate in prevailing upon Mr. Ernest R. Ashton to exhibit and explain his matchless series of pictures,

IN EASTERN LANDS,

Although Mr. Ashton is the winner of no less than twenty medals awarded at the chief photographic exhibitions of the world, he has never been induced to show, let alone describe, his collection of pictures until he made his *début* at the above gathering. It is impossible to do full justice to the exceeding beauty of many of the scenes, nor to convey in words the numerous points of interest concerned with the Eastern people, their customs at home and at business, which Mr. Ashton's slides so vividly portrayed. Several of the mosque interiors, with their magnificently decorated "Mecca" shrines, are unique views, no other photographer having been able to obtain permission to photograph them. The heartiness with which the large audience accorded Mr. Ashton a vote of thanks, proposed by the President (Mr. H. Maclean, F.G.S.), showed how greatly the lecture and slides were appreciated. The second portion consisted of members' slides, which were, as usual, explained by the President. First came an admirable set of about two dozen views in South Devon, Honiton and the Teign district. These, on account of their fine tone, attractive subject, and skilful handling, were received with great favour. Mr. H. E. Holland, by whom they were shown, being warmly applauded. Next, Mr. MACLEAN explained some of his own productions. A small set of the floral *fête* at the Hastings Carnival recalled pleasant memories of a week given up to revelry. Another set of *Flowers at Kew* seemed greatly to the audience's taste, specially approved being a picture of an exotic from the land "where it is always afternoon." Messrs. J. and A. J. Noaks, Watson, Corland, Packham, Rogers, Myrtle, and Hirst also contributed. Finally, Mr. Isaac, who handled the lantern with admirable skill, showed a dozen of his own slides. It is hard to particularise where all were good, but perhaps to a telling rendition of *The Corbière Rocks, Jersey*, should be awarded the palm, although the President was inclined to give first place to *On the Mole: Early Morning*. At the conclusion of the members' slides, the PRESIDENT gave a brief but clear explanation of the mysterious X rays which Professor Röntgen has lately given such prominence to. He then showed and described a number of pictures, or shadowgraphs, taken by Mr. A. Campbell Swinton by means of the radiant matter aforesaid.

East London Photographic Society.—January 28, Mr. E. Stone in the chair.—A lecture on

COMPOSITION AND LIGHT AND SHADE

was given by Mr. EDWARD ATKINSON, illustrated by numerous diagrams and prints. He deprecated the taking of what was termed "pretty bits," as the interest attaching to them would soon pall. In photography a pleasing result depended greatly upon the lighting of the subject, but it was all too evident that a great many seemed to overlook or ignore this salient point. Each production should convey to the observer that some definite object had been sought after, and it should be the photographer's aim to express this in a manner befitting the subject in hand. The painter's power in being able to leave out irritating details was referred to, and the best means of suppressing them in photography was explained. The rules governing the elements of a picture were treated of, and a plea for a more rigid selection of subject was demanded, if it was desired that the art should be still further advanced. The apparent easiness of photography was one of its greatest curses! For a few pounds one could procure the necessary apparatus, and forthwith sally out and snap up everything that might please, ignoring all rules which, though flexible, govern the making of a picture. He did not wish to imply that the canons of art must be strictly adhered to, but they were a foundation, at least, upon which we could work. He instanced several pictures which contravened many recognised laws, but which were highly artistic pieces of work. The great difference which could be made in a subject possessing parallel or horizontal lines by simply altering the point of sight was illustrated by diagrams, and caused a certain amount of astonishment.

Hackney Photographic Society.—January 28, Mr. J. O. Grant presiding.—Excursions and other fixtures were arranged. In a discussion as to the best method of procedure for

SNOW PICTURES,

Mr. R. BECKETT said that the common fault was to get them either too hard or too flat. Snow scenes were best taken with sunshine. Captain Abney had advised developing with very small amount of pyro to get detail, and then getting density by means of intensification. Mr. RAWLINGS advised the use of slow plates, as they were more manageable. Messrs. GUEST and RAWLINGS respectively brought up results of experiments made to determine the question as to whether negatives lost density during long fixation. Mr. Rawlings' experiments served to show that no loss of density occurred by prolonged fixation, but considerable loss of colour. In two portions of a pyro-developed negative, the yellow stain was much less apparent in the portion which had been allowed to remain in the hypo bath considerably longer than the others.

North Middlesex Photographic Society.—January 27, Mr. Mummery (the President) in the chair.—Mr. ROLAND C. WHITING gave a lecture on

WHY WE FAIL?

He went very fully into the causes of failure and the way to get over them. He began by saying that the main cause of failure in picture-making was a want of retention of purpose. If you want to succeed, keep to one or two definite aims, instead of photographing anything that comes in your way. He dealt with faults of manipulation, such as want of cleanliness, light in the dark room not sufficiently non-actinic, &c. With regard to exposure, not sufficient attention was paid to the quality of the light, and the relative quantity of light and shade in the picture itself, which constituted a great source of failure. Photographers ought to try and get the effect of motion in their pictures. It was false economy not to buy the best apparatus, and plates with plenty of silver in them gave much the best results, and all plates are the better for being backed. Don't keep changing developers; keep to one, and always mix it accurately. Plates are not properly fixed the moment they are clear, and should not be brought to the light until some little time has elapsed after they appear fixed. He ended by saying that a high standard should be aimed at, even if it is not attained. After Messrs. GOODWIN, LENNANT, BEADLE, and others had put various questions, and Mr. Whiting had replied, Mr. JOHNSON proposed a hearty vote of thanks to the lecturer, and Mr. MATTOCKS seconded, which was carried unanimously.

Mr. CHILD BAYLEY brought up some results he had obtained, in conjunction with Mr. Gifford, of

PHOTOGRAPHY BY MEANS OF CROOKES' TUBES.

He showed photographs of his own hand and that of a lady in which the bones showed distinctly through the flesh. The plate was covered with a sheet of waxed paper, then the hand was placed upon it, and all wrapped up in a changing bag of black cloth lined with red, and the Crookes' tube, excited by a ten-inch spark induction coil, was held directly over it. No trace of the cloth appeared in the prints, showing that it was transparent to these rays. He also showed photographs of metal discs in a closed box upon which a sheet of aluminium had been placed, as this metal allowed the rays to pass through; also one taken through a thick porcelain dish, but this was under-exposed. A vote of thanks was accorded to Mr. Child Bayley for the interesting exhibit.

The annual dinner was announced to be held on March 14 at the Holborn Restaurant.

Leeds Camera Club.—January 30.—The Rev. J. BEANLAND gave a lecture and demonstration on

THE AFTER-TREATMENT OF PLATINOTYPE PRINTS,

being a supplementary course to his previous demonstration on Platinotype Printing, delivered before the same Club in March 1895. Mr. Beanland showed how comparative failures in printing could be turned into complete successes by careful after-manipulation, and also demonstrated his methods of producing numerous tones, including brown-black, blue-black, Vandyke, purple, sepia, green, and blue. For this after-treatment it is essential that the prints be thoroughly fixed in hydrochloric acid, after development, to remove the last trace of iron, otherwise unequal toning, or iron stains, are sure to occur. For various shades of Vandyke brown and red the demonstrator boils two drachms of Packham's tioctorial powder in five ounces of water for a few minutes, and, when cold, adds one ounce of alcohol, and makes up the solution to six ounces with water. Uranium nitrate gives very pleasing tones, but, when used with ammonium sulphocyanide (the usual method), the toning is very irregular, and decidedly fugitive. He therefore recommends one drachm each of ten per cent. solutions of uranium ferricyanide) of potassium and sodium sulphite, six ounces of water, and three drachms of acetic acid. If the result is not satisfactory, the original colour can be restored by the application of a weak solution of ammonia. A beautiful sea-green tone is obtained by immersion in a mercuric solution, followed by chloride of iron, and a blue image by the application of the ordinary ferrous-oxalate developer for a few moments. The results produced by Mr. Beanland during his demonstration were highly satisfactory, and his friendly advice much appreciated. On the suggestion of Mr. Vevers, a subscription to the Traill-Taylor Memorial was opened, and a considerable amount promised by members preseut.

Liverpool Amateur Photographic Association.—January 30, the President (Mr. J. Sirett Brown) in the chair.—Captain T. Lamb, Captain H. Pomeroy, and Messrs. C. E. Hancox, A. Von Heyder, Harold Coventry, and Francis H. Edwards were elected members. The PRESIDENT drew attention to the prospective engagements, especially to the auction on February 13, and to the engagement of the well-known lecturer, Mr. Eadweard Mugbridge, for March 19 in the City Hall. The medals awarded in the recent competition were then presented to the winners. This concluded the business part of the meeting, after which Dr. J. W. Ellis was called upon to deliver his lecture entitled *The Black Mountains and Golden Valley; a Holiday in King Arthur's Country*.

Oxford Camera Club.—January 27.—A demonstration of the new

URANIUM INTENSIFIER

of the Cresco-Fylma Company was given by Mr. H. A. HOLLIDAY, one of the Secretaries. In the course of many experiments on the process, he had discovered some methods of working which gave a superior result to those recommended by the manufacturers. Thus, in order to get the greatest possible contrast, he much over-intensified the negative, and then placed it in a very weak solution of soda carbonate or ammonia. This, while reducing the picture as a whole, acted with most effect on the lighter portions, so increasing the contrasts. The intensifier seems to act mainly by changing the colour to a very non-actinic reddish brown, the printing time being much increased. The solution has no injurious action on the film, as is sometimes the case with mercury bichloride, and is practically non-poisonous. There is the further advantage that the whole intensification can be removed by alkalies if necessary, leaving the negative as at first. The lecturer also showed the toning of bromide prints, by the same solution, to a warm brown, which was very pleasing.

Plymouth Photographic Society.—January 24, Mr. E. H. Micklewood (Vice-President) in the chair.—Mr. STANNING (Hon. Treasurer) reported that the year's receipts amounted to nearly 11*l.*; and, after buying a lantern for the use of members, there was a debit balance of 17*s.* 8*d.* Mr. R. RUGG MONK (Hon. Secretary) reported that, twelve months ago, after taking counsel with friends, he called a meeting of all interested in the formation of a Photographic Society for Plymouth. Eighteen responded to the invitation, the Society was formed, and it now numbered fifty members. It was unwise to judge of vitality and genuine work by mere numbers, but, tested by the quality of the papers and demonstrations given, and the number of members attending, the result was excellent. The Society's Exhibition—albeit a private one—was well attended, and much interest was taken in it by members and their friends. It already afforded evidence of ability amongst the more modest members, and it

was hoped their Exhibition would this year be more pretentious, and be an open one. The summer photographic excursions were well attended and very enjoyable. It was hoped that members would continue to show a keen interest in the work of the Society, and, by widening its scope, by introducing new blood, and by offering to read papers, or to demonstrate, help forward the delightful art they were combined to promote. On the motion of Mr. J. HAYNE PILLAR, seconded by Mr. A. MOORE, the reports were adopted, the CHAIRMAN remarking that, whilst the Hon. Secretary had spoken in eulogy of his services, the Society was far more indebted to Mr. Monk. On the motion of Mr. DUNSTAN, seconded by Dr. BRENTON, Mr. Micklewood was by acclamation elected President; Mr. H. S. Hill and Mr. W. Aver Duncan were elected Vice-Presidents, Mr. R. Bowden declining the honour. Mr. Stanning and Mr. R. Rugg Monk were unanimously elected Hon. Treasurer and Hon. Secretary respectively. Replying to a vote of thanks to the officers, the Chairman said Mr. Monk was the father of the Society, and had by his ability and energy contributed largely to the success it undoubtedly was. A ballot resulted in the election of Mr. J. D. Turney, W. H. Harris, T. Algate, and J. H. Pillar as the Committee, and Mr. Johnson was elected the Auditor. An attractive programme for the session includes a platinotype demonstration and a lantern evening.

FORTHCOMING EXHIBITIONS.

1896.

February 27-29 ..... Woolwich Photographic Society.

March 2-6 ..... *South London Photographic Society. Hon. Secretary, Charles H. Oakden, 30, Henslowe-road, East Dulwich, S.E.

ALBUMEN PAPER.

To the EDITORS.

GENTLEMEN,—In a reference to albumen paper, on page 66 of your issue of January 31, you remark that it "certainly dies very hard."

I believe this is fully explained by the fact you state in the succeeding paragraph, namely, that "there are features in good albumen prints which compel admiration for the process, and are not always possessed by other methods of printing."

But the charge is brought against albumen prints that they are not permanent. In dealing with this subject in an American journal last month, Mr. W. H. Sherman describes a portrait of Bayard Taylor, taken in 1864 or 1865, as to which he remarks: "It is hardly posaible that a print by any other process, whether carbon or platinotype, would have changed less in any respect than this photograph has changed in all these years."

In an article on the same theme in the *St. Louis and Canadian Photographer* (January), the writer points out that, with respect to prints that fade and turn yellow, "the compound toning bath, imperfect washing, and insufficient fixing are some of the causes to which this trouble is to be attributed;" and he proceeds: "Photographers would do well to pay more attention to the production of lasting prints, and we hear that several parties here in America are coming back to the use of albumen paper, and have even offered to reprint free of charge work given out these last two or three years. Mr. Backrach, in Baltimore, is one who deserves credit for taking this step in the interest of his reputation at no small sacrifice of money, and we think it is a step in the right direction."

In connexion with Wilson's *Photographic Magazine* the following question was put to its readers: "Do you practically find the new printing papers to give as satisfactory and permanent results as albumen paper?" and (of course, in addition to other replies expressing different opinions) the following were some of the answers received and printed in the December issue:—From James F. Ryder, Cleveland, Ohio, 'No, sir, not all kinds;' from F. G. Schumacher, Los Angeles, Cal., 'Were I to choose between aristo and albumen, I would prefer the latter;' from R. D. Beem, Greenville, Ohio, 'American aristo papers have proved permanent, the gelatine papers have not; but albumen paper gives better tones, has more depth and better harmony of tone than the ready-sensitised glacé papers;' from Charles Fritsch, Pittston, Pa., 'I have just gone back to old albumen;' from Arthur & Philbric, Detroit, Mich., 'Not as permanent as albumen prints;' from Henry Holler, Brooklyn, New York, 'Decidedly not.'"

I am inclined to think that a similar question put to photographers in this country would elicit the fact that albumen paper has not been given up to the extent that many suppose, and that, amongst those who have given other papers a trial, there is a tendency to return to the old favourite.—I am, yours, &c., W. T. A. B.

SUPPOSED MISPLACED HISTORY.

To the EDITORS.

GENTLEMEN,—Your correspondent, "Another Old Member," is very complimentary to some imaginary person (with which I have nothing to do), but he is very severe on me for, as he says, confounding Charles II. with James I.; in fact, he makes this accusation the only coherent part of his letter, for which I am far from blaming him. When one writer accuses another of a "feat of inaccuracy" and "an act to be condemned in an ordinary individual," I think the one condemned has a right (of which I joyfully avail myself) to demand chapter and verse. Therefore I ask "Another Old Member" to quote his history and prove me wrong. He says that the words which I applied to Charles II. belong to James I., and I am afraid he rather jeers at me for the supposed mistake; nevertheless, I am sorry to take the little flutter out of his sails by giving my references first and asking him to follow.

I thought it was known to everybody who can read and write that the words in question occur in the *Mock Epitaph on Charles II.*, written by the Earl of Rochester. Here it is:—

"Here lies our sovereign lord the King,
Whose word no man relies on;
Who never said a foolish thing,
And never did a wise one."

I won't stop to imagine how dreadfully ashamed of himself the erudite "Another Old Member" must feel as he reads this, and how, if he is wise, he makes a vow never to be cocksure any more; or, if otherwise, or other than wise, he is tearing through all the books within reach to try to discover who misled him in this exceedingly important matter. Perhaps my astonished friend is not yet convinced, and wants still more authority. Let him turn to Sir Walter Scott's *Tales of a Grandfather* (Scotland), chap. xlix. Speaking of the well-known lines he says: "The satirical epitaph written upon him (Charles II.) at his own request, by his witty favourite, the Earl of Rochester, is not more severe than just."

In my letter the words in italics only were applied to "Cosmos;" does "Another Old Member" say the other lines also apply? It is he who has compelled me to quote them.—I am, yours &c.,

AN OLD MEMBER.

P.S.—"Another Old Member" says nothing about the really serious part of my letter. He would have done better if he had backed me up in that £1000 a year matter.

PHOTO-CHROMOSCOPES.

To the EDITORS.

GENTLEMEN,—In the last issue of THE BRITISH JOURNAL OF PHOTOGRAPHY I notice a communication from M. Léon Vidal, in which he describes the chromoscope of M. Natchet, and suggests that there "may be other photo-chromoscopes, quite as simple as Mr. Ives's, that produce equally remarkable results."

My object in writing now is to describe one of those "other photo-chromoscopes" of which I am the inventor.

As will be seen from the enclosed sketch, my apparatus is somewhat similar in outline to those of Mr. Ives and M. Natchet. We have evidently been working on the same lines; but, unlike those gentlemen, my chief aim has been to produce, not a colour stereoscope only, but a colour camera, by which one could obtain the three negatives in one short exposure, and afterwards employ the same apparatus for viewing the results.

Early in 1894 it occurred to me that there must be some simple way of combining the three images, and I soon hit on the idea of the "step" arrangement, by means of which I was able to bring them into the focus of one lens.

I constructed my first instrument of the most primitive materials. It was made out of an old box, and had plain glass mirrors for reflectors. Even with this arrangement I was able to show my friends very encouraging results. Nevertheless, I considered these results anything but perfect, owing to the double reflections from the two surfaces of the plain glass mirrors. To surmount this difficulty, I tried coloured glasses instead, but found that they only partially remedied the defect. I next turned my attention to platinised glass mirrors, but, owing to their unequal surfaces, apparently inseparable from their manufacture, the resulting distortion completely barred their use in a camera. Both kinds of mirrors, however, gave fair results when the instrument was used as a viewing apparatus.

It was not until I conceived the plan of using plain glasses slightly silvered on one surface that I succeeded in producing to my satisfaction an instrument which could be successfully used as both camera and viewing apparatus, and felt justified in applying for a patent, which I did in the beginning of last year.

By this method of constructing the colour camera the exposures are wonderfully shortened, as the whole of the light passing through the lens is utilised; and, when I have perfected certain minor details, I look forward to securing instantaneous colour photographs out of doors, as well as portraits in colours in the studio, without the necessity of inconveniently prolonged sittings.

The accompanying drawings give a general idea of my apparatus. Fig. 1 shows it in use as a camera. P, P^1, and P^2 are the dark slides containing the sensitive plates, in front of which are placed the colour

FIG. 1.

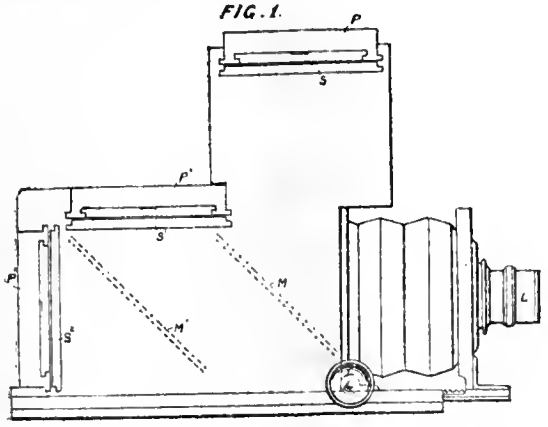

FIG 2

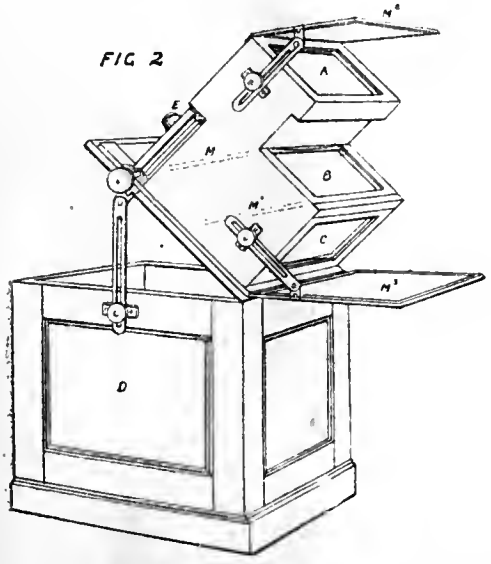

screens S, S^1, and S^2. M and M^1 are the two mirrors, and L is the lens. Fig. 2 shows the apparatus as a viewing instrument or photo-chromoscope. A, B, and C are the three transparencies for the red, green, and blue-violet sensations respectively, each backed with its appropriate colour screen, and the whole fitted in frames which slide in the grooves for taking the dark slides. M and M^1 are the two mirrors already described. M^2 and M^3 are two reflectors for illuminating A and C. E is an ordinary lens or eyepiece used in place of the photographic objective. D is a box arranged as a convenient stand for the instrument, and to hold the same when not in use.

It is obvious that, by employing a pair of lenses, the instrument can be used either as a stereoscopic colour camera or a stereo-photochromoscope.—I am, yours, &c.,

B. J. EDWARDS.

The Grove, Hackney, February 4, 1896.

To the EDITORS.

GENTLEMEN,—The photo-chromoscope, which Mons. Vidal praises and credits to Mons. C. Nachet (p. 78), is my own invention. Mons. Vidal's drawing does not show a single detail (nor does he mention one) which I had not patented on July 3, 1894 (date of filing of complete specification in U. S. Patent Office). The photo-chromoscope, which has heretofore been ascribed to Mons. Nachet, is a totally different, irrational, and (in my opinion) worthless contrivance. It will not do for him to claim, at this date, the instrument which I patented so long ago.

Different men do sometimes hit upon the same idea; but I do not know of a single authenticated instance of such a complete instrument or machine which has developed exactly alike as to detail in the minds of two men. The duplication of the form and arrangement of the photo-chromoscope proper, and its combination with the tray for chromograms, hinged reflecting mirror, devices for fixing the angles of inclination, and the phraseology of description, I feel sure is something more than a coincidence of thought. Certainly Mons. Nachet, who knew no better than to try to reproduce compound colour sensations by viewing one colour element through one eye, while viewing the others through the other eye (as in his instrument of about two years ago), is not the man to duplicate my thoughts in detail.

Mons. Nachet cannot manufacture the apparatus in France, without infringing my patent rights; and Mons. Vidal should not have credited to Mons. Nachet the invention of an instrument which he did not show until a year (?) after it had been publicly exhibited and described by me. I am not, however, surprised at this action, for I have, on other occasions, received similar treatment from Mons. Vidal and his friends.—I am, yours, &c.,

F. E. IVES.

119, *Shaftesbury-avenue, London, W.C., February* 1, 1896.

THE RECENT LIMELIGHT COMPETITION.

To the EDITORS.

GENTLEMEN,—I was much surprised to see, in your report of the jet competition held on January 22, that Mr. Scarborough's jet and my own, which were the two most powerful jets exhibited, "were declared to be of equal light-giving power." This version of the trial I consider hardly fair to me for the following reasons, which many gentlemen present will, doubtless, recollect and be willing to corroborate if necessary.

At the first trial the reading was given in my favour, and Mr. Scarborough had to advance his lantern before those present considered his light equal to mine. Not being satisfied with this result, he demanded a second trial, which was accorded to him, the result being again declared in my favour. Some delay then occurred while other jets were trying conclusions with me, my jet being kept burning the whole evening while these were being disposed of.

Mr. Scarborough, being still dissatisfied, desired another reading, the result this time being that both lights were declared equal; but, as I previously mentioned that my jet had been burning the whole evening and the supply of gas must have run very low, I do not consider this test conclusive, but, as I understood Mr. Hearson to say that my jet scored one point above Mr. Scarborough's on the whole trial, I did not press the matter further. I think it also necessary to state that my jet is constructed with a view to extreme portability as well as high illuminating power. The mixing chamber of Mr. Scarborough's jet was of most unusually large dimensions, and was not, I believe, the one he competed with at the former trial, but was considered some twenty-five per cent. more powerful.

As an ether saturator present was declared to equal the best mixing jet, I think it should be known that this result was obtained when the saturator was coupled to my jet for trial.—I am, yours, &c.,

G. W. GWYER.

Bourneville, Sneyd Park, Bristol, February 3, 1896.

Answers to Correspondents.

*** *All matters intended for the text portion of this* JOURNAL, *including queries, must be addressed to* "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 2, *York-street, Covent Garden, London. Inattention to this ensures delay.*

*** *Communications relating to Advertisements and general business affair should be addressed to Messrs.* HENRY GREENWOOD & Co., 2, *York-street, Covent Garden, London.*

PHOTOGRAPHS REGISTERED:—

Mr. A. Barnes, 14, Cheap-street, Bath.—*Photograph of a Roman bath, excavated at Bath.*

Mr. T. Taylor, 481, High-street, Kirkcaldy.—*Photograph of the late Rev. J. Johnstone, B.D.*

Mr. W. Atkinson, 67, Grove-road, Eastbourne.—*Photograph of the late Alderman W. E. Morrison.*

*** We have again, through extreme pressure on our space, to hold over much interesting matter. Several contributors and correspondents will therefore understand the reason their articles, &c., have been delayed in publication.

WYNNE'S EXPOSURE METER.—F. W. The address of the maker is Wrexham.

FREE PORTRAITS.—L. NAISH. Thanks. We have very frequently referred to the matter.

LENS FOR COPYING.—J. B. S. asks: "Can you please tell me if a Dallmeyer 10×8 triple achromatic lens would be suitable for reproduction work for half-tone blocks?"—In reply: Yes.

FORMALIN.—IN LIMINE asks: "Where can formalin be obtained by purchase?" In reply: Of Messrs. Fuerst Bros., Philpot-lane, E.C. We shall be detailing further experiments shortly.

FRAMES, &C.—RALPH LESLIE. Consult the advertisements in the advertisement columns of the ALMANAC. You will find there the markets you require. It is against our rule to recommend any particular manufacturers.

GELATINE.—C. TURNER.—If the gelatine has got mouldy from being stored in a damp place for several months, we should not recommend its use for experiments in dry-plate making, or even for enamelling silver prints with.

BOOKS ON PHOTO-MICROGRAPHY.—PETTINGELL says: "Would you oblige me by letting me know the names and publisher of any works on photo-micrography for making slides and negatives from microscopic specimens." In reply: Messrs. Iliffe & Son, St. Bride-street, publish such a book by Mr. Audrew Pringle.

BURNISHING CARBON PRINTS.—RONALD FIELD. Carbon prints can be burnished with a hot burnisher, but they must be perfectly dry at the time, otherwise they will suffer injury. Lubricate them with the usual Castille soap lubricant.

ADDRESS WANTED.—G. PITCHER says: "I see it mentioned in your valuable paper that Messrs. F. S. Thorn & Co. manufacture a generator for calcinm carbide. I should be glad of address." In reply: The address is 169, Camberwell New-road, S.E.

RÖNTGEN PHOTOGRAPHY.—H. RENBOLD says: "Would you be so good as to enumerate the necessary articles and directions for the production of the Röntgen photographs?"—In reply: Read Professor Röntgen's paper in the last number of the JOURNAL.

LENS FOR GENERAL WORK.—T. BARCLAY wants to know the best lens, at a moderate price, for general all-round work—out-door work, groups, &c. The best and most usefnl lens for such work, at a moderate price, is one of the "rapid type." One of about sixteen inches focus will be the most suitable for 12×10 pictures.

PHOTOGRAVURE PATENTS.—EXPERIMENTALIST (Notts.). So far as we know, there are no patents in connexion with photogravure. There were some, but we believe they have all lapsed now. You can certainly practise the process, which has during the past year or two been demonstrated before the societies without let or hindrance.

STUDIO.—LEACH. Either sketch No. 1 or No. 3 is preferable to any of the others. As the studio will be shaded from the south by a very high building, we should recommend No. 3, the "lean-to form." Hot-water pipes for heating will be found far more cleanly than a coke stove, and gas fires, to heat so large a studio, will prove somewhat costly.

AMATEUR AND PROFESSIONAL.—W. G. C. asks: "If a person keeps a shop selling photographic materials, and also takes photographs of the neighbourhood, which he shows in his window, 'and sells' in the usual way of business, can this person be considered an amateur, and exhibit in amateur exhibitions as an amateur?"—Certainly not. He is in every sense of the term a professional.

PATENT.—INVENTOR asks: "What is the cheapest protection I can get for a new piece of apparatus? Would not registration be cheaper than a patent?"—Registration would be of no use. The only protection is a patent. A patent for four years costs four pounds, or provisional protection, which lasts for nine months, costs but one pound. Of course those are the Government fees, and, if a patent agent is employed to take out the patent, his charges will be an addition.

COPYING OIL PAINTINGS.—It is not usual to prepare the surface of oil paintings with anything prior to photographing them, beyoud sponging them over with clean cold water, to remove the dirt. Various substances have, at times, been recommended for treating the painting with — glycerine amongst the number—but their use is attended with future danger to the picture, and are now seldom used; indeed, the owners of valuable paintings will not allow of their employment.

OSITIVE INSTEAD OF NEGATIVE.—O. ST. JOHN KNELLER writes: "Some time ago, on developing an instantaneous photograph, I was greatly surprised to find the image was positive instead of negative. Should you think this matter worth further investigation, I should be pleased to furnish any further details in my power."—There is nothing novel in the phenomenou. The plate was either (1) over-exposed, or, (2) before development was exposed to the dark-room light too long.

COPYRIGHT.—W. S. W. says: "An operator who has left me, aud is setting up in business for himself, says that all the views he took while in my employ I have no copyright in, and that I can't publish any of them if he likes to prevent me; also, that if he likes he can compel me to hand him the negatives."—Nonsense. Although you may have no copyright in the negatives, they are your property, and, as he took them as your servant "for a valuable consideration," his salary, he can have no copyright in them.

COST OF NITRATE OF SILVER.—T. WALLER writes: "I am commencing some experiments which will probably, before they are completed, take forty or fifty ounces of silver. Will you please tell me if it would pay me best to make the nitrate or to purchase it? What do dry-plate makers aud other large consumers of the nitrate do?"—They purchase the nitrate, and you will find it far more economical to do the same. Making nitrate of silver is not a pleasant operation, and, without proper appliances, there will be considerable waste.

CEMENTING GLASS.—J. READER says: "I have an old glass dipper, such as was used for the silver bath, and the glass strip has become detached. Can you tell me of anything to stick it on again with that will not injure the silver solution?"—It may be cemented on again with either marine glue or shellac, neither of which will hurt the solution. We prefer the former, as it is not so brittle as the latter. Both the dipper and the slip should be made very hot before the cement is applied, aud then the two glasses should be pressed firmly together till they are cold.

CRITICISM OF PHOTOGRAPHS.—ALPHA says: "I enclose a few photographs for criticism and advice. Any hints for the improvement of my work which you may give me I shall esteem a great favour. Perhaps I should explain that I am only a beginner; it is only six months since I first began photography. I have got very fond of the work, and am anxious to improve.—In reply: For a six months' worker the photographs are, in the main, capital. 1. A very good bit of portraiture. 2. Negative possibly too hard, the print being chalky. 3. Negative appears to have been either fogged or over-exposed. 4. Very good, but the vignetting does not improve the effect. 5. Slightly out of focus. 6. Ditto. 7. Excellent. 8. Same as five and six. Summing up, we should say that, artistically, the figure studies are very promising, and that, as regards selection and treatment, the outdoor subjects give scope for improvement in those respects. By all meaus write again.

NEGATIVES OF SITTERS.—AMATEUR (London, N.W.) says: "I am an amateur, and want first-class negatives of some of my friends to print from myself. Of course, as I can print, I do not want to pay the price for prints that good professionals charge for them. On applying to some artists, they indignantly refused to take the negatives at all, and others only at such a price as is prohibitive. Is not this very unfair to one who knows the cost of everything that is used?"—No. Every one is entitled to conduct his business on his own terms, and many photographers guard against their reputation being injured by inferior prints being produced from their negatives by declining to part with them on any terms.

PHOTOGRAPHIC SCHOOLS; HELIOGRAVURE; PHOTO-CERAMICS.—MADRAS says: "I shall be greatly obliged if you will answer the following questions: I. Are there any schools or classes of photography for amateurs in London? aud, if so, where? 2. Is the heliogravure process peculiar to one firm, or is it generally used by photographers? If the latter, where should one apply for particulars? 3. From whom could a professional photographer get reliable information regarding photo-ceramics, and where are the best materials for the process obtainable?"—In reply: 1. The Polytechnic, 309, Regent-street, W. Write to the Secretary for particulars. 2. Heliogravure is a name given occasionally to photogravure, which anybody may work. 3. Messrs. Dawbarn & Ward, Farringdon-avenue, publish a book on the process.

NON-ACHROMATIC LENS.—ALPHA says: "An answer will oblige on the following: There are some small lenses sold for hand cameras—they are called, I believe, "periscopic," and consist of two glasses, something like two small watch glasses at the end of a tube. What I wish to know (the glasses not being achromatic in the sense that a single combination achromatic lens is) does the visual and chemical focus coincide? In other words, does the lens require adjusting nearer to or farther from the focussing screen than the picture shown thereon in order to take a correct photograph?"—The chemical and visual foci will not coincide, and the lens will require to be adjusted nearer to the focussing screen after the object is focussed. The distance will be about one-thirtieth of the focal length of the combination; but the exact distance is best ascertained by experiment.

TONING.—AN OPERATOR OF TWENTY YEARS' EXPERIENCE writes: "May I claim your assistance under the following circumstances? I am at present engaged as operator and retoucher with a man in London, and my employer lately has taken to sensitising his own paper, which he floats on a seventy-grain bath for half a minute, and keeps the prints from Monday to Friday night, when they are all toned. He makes the toning bath of acetate of soda, and expects seven grains of gold to tone twelve sheets of paper, but he cannot get them to tone quickly, taking about two hours to tone the twelve sheets. The consequence of this is that he accuses me of putting something in the toning bath to stop its action. He suggests hypo. I must here mention that a sample of ready-sensitised paper toned in the same bath with the home-sensitised gave perfectly satisfactory results, which he admitted. If I send you some of the bath that is left, with our home-sensitised paper, would it be too much to ask you if you would be kind enough to test the bath to prove that hypo has not been put into it, or any other chemical likely to stop the toning? I am in a most unpleasant position, and should feel extremely grateful if you would settle the matter for me. In my opinion it is a most wicked aud unfounded charge to make against an assistant without positive proof. If you make any charge, I will most willingly bear the expense, and be thankful to clear myself of this wretched accusation."—Twelve sheets of paper is too much to expect seven grains of gold to tone quickly if deep tones are desired, particularly with home-sensitised paper, after it has been kept several days. If one sample of paper tones well in the bath, it is a clear proof that the bath is all right, and that the charge is quite unfounded and equally unwarrantable. Much as we sympathise with our correspondent, our time will not allow of our making the desired examination.

RIGHT TO NEGATIVE; CAMPHOR IN OIL. — JAMES BENTLEY writes as follows: "I would like to ask your opinion on a case that has just occurred between me and the Rector of St. Mark's, Shilton, a suburb of Hanley. On Monday, January 27, after the church had been reopened after renovation and installation of electric light, I wended my way down about ten a.m., and when looking inside I saw the curate (and as I often take my camera with me, as on this occasion), I asked him if he had any objection to me taking the inside. He said, No. And he stayed with me, aud, after my taking a view looking towards the chancel, hs asked me to take him one including the two altars in the church, which I did, and, to my surprise, at night, while the negatives were wet, the rector sent and demanded the negative. Of this I took no notice, but sent him word I would supply him with a print of them. On Saturday last I met him, and told him, as an amateur, I did not want to make money of them, but took them for the love of the art; but he threatened me with legal proceedings if I did not send him the negatives. Now, sir, I wish to ask you, as I am only a working man, whether he can do any such thing as demand the negative, when I had permission of the curate to photograph the interior of the church? In your issue of January 3, 1896, a question appears *re* burning oil in lantern, and whether camphor improves the light. I can say from experience that the additiou of a penny square of camphor to the quart whitens the light and makes it less smoky; but to get the light *par excellence*, if expense is no item, use olive oil, and he will get a splendid light and smokeless. This is what I use for my cycle lamp, and can recommend the same to my photographic friends who cycle and photograph, which I have now done for several years."—As the negatives were taken with the consent of the curate, and two at his suggestion, we should certainly not give them up. The rector's request is unwarrantable, and, as for the threatened legal proceedings, it is simply "bluff," which we are surprised that any clergyman should indulge in. Thanks for reply about the addition of camphor.

EX CATHEDRÂ.

We are pleased to learn, from a letter sent us by Mr. Drage, the Honorary Secretary of the Convention, and which will be found in our correspondence columns, that the arrangements for the Leeds meeting in July next are in process of completion, and that Messrs. J. H. Walker, Godfrey Bingley, and Herbert Denison, who comprise the principal members of the local executive, are already hard at work in the endeavour to make the gathering a success. From personal knowledge of the gentlemen named, we are persuaded that they will spare no effort to render the Leeds meeting of the Convention a memorable one, and we hope, and indeed are confident, that they will find their labours rewarded, if only partially, by a large gathering.

* * *

Mr. T. C. Turner (of Messrs. Turner & Drinkwater, Hull), to whose *Trilby souvenir* in photogravure we had occasion to make appreciative reference a fortnight ago, sends us a number of albumen prints from negatives taken of several of the principal performers in that piece. The prints have a richness and beauty about them to which we are not often accustomed in modern albumen prints, and several photographers of long experience, to whom we have shown them, pronounce them to be exceptionally fine. With such examples of flawless surface prints before us, it seems anomalous that we should have to refer to albumen printing as on the down grade in photographic estimation.

* * *

Professional photographers may possibly profit by a useful hint which Mr. Turner gives as to the treatment of negatives from which large numbers of prints are taken. He says: "The negatives of *Trilby* have been used for printing hundreds of copies from each plate. They are kept clean and bright by washing in pure alcohol every twenty-one days and revarnishing. It is worth the trouble for heavy printing."

* * *

Reverting to the *Trilby souvenir*, here are some further observations by Mr. Turner which, as they are of interest to so many professionals at this juncture, we take the liberty of reproducing. Our correspondent advises his brethren not to be so ready as some appear to be in disposing of their profitable rights to printers and publishers. It is sound advice. "The feature of most interest to the profession in this *souvenir* production is that the whole transaction has remained entirely in my hands. I hear so often of photographers allowing publishing rights for a guinea or five guineas, when probably printers or publishers are going to make a large sum out of the use of those photographs, and it does seem so foolish.

* * *

"The *Trilby souvenir* was produced on these lines. I arranged to photograph the company, and to supply Mr. Tree with the best *souvenir* I could get up at a fixed price, which, of course, had to be strictly moderate. The copyrights were to be my property, and I had the right of publication outside the theatre. It thus became a question of supplying the theatre on the one hand and the publisher on the other, and the profits in a fair degree came to the originator of the work. Now every *souvenir* sold in this country or in America directly benefits me instead of the printers and others. I need hardly add, too, that the theatrical managements reap a direct benefit by this *modus operandi*, both on the score of price and the method of reproduction, which the majority of good photographers understand better than publishers. To repeat myself more briefly, I would say that, while printer and publisher are

absolutely necessary, the photographer in these matters should be master of the position, and not, as he sometimes degenerates to be, the servant of one or the other or both."

* * *

Our American cousins are early in the field with acetylene generating and projection apparatus for lantern work. Messrs. Walmsley, Fuller, & Co., of Chicago, have sent us a copy of their catalogue, which is entirely devoted to the acetylene light for projection and photo-micrographic purposes. It is replete with instructive hints to intending users of acetylene.

* * *

Our readers will, doubtless, be glad to know in advance the subjects that are set down for discussion at the remaining meetings of the Royal Photographic Society during the current session, and we accordingly append the necessary particulars. It will be observed that a singularly varied, interesting, and unconventional programme has been arranged :—February 18, Photo-mechanical Meeting, *The Working up and Hand Engraving of Half-tone Blocks*, by Mr. W. Cheshire. February 25, Technical Meeting, *The Stereoscopic Photo-chromoscope*, by Mr. F. E. Ives; *Messrs. Newton's Simple Method of Projecting Stereoscopic Pictures*, by Mr. T. E. Freshwater, F.R.M.S.; *Stellar Photographs taken without a Driving Clock*, by Mr. J. Lunt, B.Sc., F.C.S. March 10, Ordinary Meeting, *Notes on Medical Photo-micrography*, by Mr. Edmund Roughton, F.R.C.S., and Mr. Charles Cosens, M.R.C.S. March 17, Photo-mechanical Meeting, *Screens for Process Work*, by Captain Collardon; *A Note on Photogravure*, by Captain Collardon. March 24, Technical Meeting, *The Relative Colour Sensitiveness of Ordinary and Isochromatic Plates*, with a demonstration, by Mr. F. E. Ives. April 14, Ordinary Meeting, *On Printing Densities*, by Captain W. de W. Abney, C.B., F.R.S., &c. April 21, Photo-mechanical Meeting, *Photo-mechanical Notes of Historical Interest*, by Mr. T. Bolas. April 28, Technical Meeting, a demonstration of Woodbury printing and its applications, by Mr. J. D. Geddes. May 12, Ordinary Meeting, *The Recording of High Temperatures by Photographic Means*, by Professor W. C. Roberts-Austen, C.B., F.R.S., &c. May 19, Photo-mechanical Meeting, *Photo-mechanical Methods in Austria*, by Mr. Ignatz Herbst. May 26, Technical Meeting. Apparatus for photography on small plates (smaller than quarter-plates). Those members who can assist in this matter, especially by exhibiting apparatus, are invited to communicate with the Secretary. June 9, Ordinary Meeting, *Cellulose and its Derivatives*, by Messrs. Cross and Bevan. June 16, Photo-mechanical Meeting. June 23, Technical Meeting.

* * *

The Vienna correspondent of a daily contemporary says that "highly sensational intelligence comes from Rome concerning an alleged invention of Professor Salvioni, of Perugia, which, if true, will revolutionise optics and considerably modify even certain social institutions. The Professor read a paper before the Medical Academy on Röntgen's recent discovery, and described the instrument which he (Salvioni) has just invented, by means of which rays of invisible light are made to impart to the eye the capacity of seeing through all objects which those rays can penetrate, and of beholding the contents of opaque receptacles. Salvioni, not content with this description, is said to have produced his invention, and shown the physicians the contents of a closed aluminium box."

Many authorities are inclined to think that the practical value of the application of the X rays to photo-surgical purposes has been overrated. Among others, Dr. Vaughan Harley, in the course of an interview, is reported to have said that Professor Röntgen's discovery was scientifically of absorbing interest, but at present, so far as surgery was concerned, it was not of much use practically. The bones of a hand, by means of the new rays, could be photographed in two minutes, but, before such a result could be obtained with the thicker portions of the body, there must be a further development of the rays. To photograph the trunk would take from fourteen to twenty-four hours, and for a subject to remain quiet during such a prolonged period was a physical impossibility. Quite recently Professor Ramsey, the discoverer of argon, used the Röntgen method in an endeavour to ascertain the locality of a bullet which had entered the fleshy part of a man's leg. The sufferer exhibited much patience, but the rays were not powerful enough to affect the photographic plate in a reasonable time. The great obstacle to successfully photographing through deep layers of flesh was the difficulty of making a good bulb in which to produce the rays.

PHOTOGRAVURE *VERSUS* THE "NEW ART."

It is not very long ago that Professor Herkomer, R.A., in one of his speeches, strongly denounced photogravure as "a very evil thing." Now he is figuring as a joint patentee with Mr. Henry Thomas Cox of a process for mechanically producing printing plates from oil paintings, and which he is vigorously exploiting. A syndicate has been formed to work the process, and a week or two back it was demonstrated at the Fine Art Society's rooms before the art representatives of the lay press. The critiques were wonderfully unanimous about the virtues of the process, and so much so in the same language, that it suggests that they were all inspired from the same source. The technical press was not invited, but probably there was a reason for that.

Let us just consider this new process of Messrs. Herkomer and Cox, and see if it is likely to prove in practice superior to, or so good as, the "very evil thing" it is intended to compete with commercially. The process, as demonstrated, is this: The artist himself produces his picture on a silvered copper plate, with a particular kind of ink or paint, and, while the colour is still tacky, it is dusted over with a brown powder, which adheres to the paint in proportion to its thickness. It has been stated that the coarser particles adhere only to the deepest shadows, where the paint is thickest, and the finer ones only on the more delicate tints, where it is thinnest, so that a discriminating grain is said to be obtained. The superfluous powder is then brushed off, when the plate is ready to be handed over to the "painter engravers' syndicate" to make an electrotype from. This electrotype forms the printing plate.

A little mystery has been made about the particular paint and the brown powder which is to be supplied by the syndicate. On reference to the specification of the patent, we find that the paint is composed of equal parts of almond and castor oils, mixed with German or lamp-black. In the specification it is mentioned that the castor oil is to retard the drying, but those conversant with oils would say that it was the almond oil which fulfilled that end, that being a non-drying oil, whereas the castor is a drying oil, though a somewhat slow one. The powder, as given in the specification, is a simple

mixture of powdered asphaltum and bronze powder in equal parts.

The method of obtaining the grain is precisely analogous to the Waterhouse process, from which the idea was probably obtained. In this process the granular matter—sand, powdered glass, or the like—is applied to a gelatine relief—an ordinary carbon print on a silvered copper plate, while the image is in a moist and adhesive condition; and, in the Herkomer-Cox process, it is applied to a hand-painted picture, on the copper, in oil colour. In the Foxlee modification of the Waterhouse method, powdered asphaltum, or resins, are used instead of the sand or glass. In each of these processes the granulated picture is afterwards electrotyped, and the electrotype forms the printing plate, as in the "new-art" process. There is this difference between the old and the new processes: in the Waterhouse the granular matter is removed before the electrotype is made; in the new one it is not, consequently, that portion of the grain which is relief in the one case is in intaglio in the other.

Let us now consider the Herkomer-Cox "new-art" process, as compared with photogravure, from a practical and business point of view. It is claimed for the former that the original touch of the artist is retained without any intervening operations; but will it be? A touch will be retained, it is true; but will it be *the* touch? We say, No! It is pretty well known that, if a painter attempts to translate one of his own works into monochrome, in nine instances out of ten the result is a failure, or, at least, is far inferior to what it would have been had the work been done by an engraver. As the powder is said to adhere in proportion to the thickness of the paint, the artist will have to take thickness of colour, as well as tones, into consideration in his manipulations. In the demonstrations of how the grained paint *cliché* is produced, in addition to brushes, leathers, dabbers, pointed bits of wood, the finger tip, under cushion of thumb, &c. were used. How far the ordinary artist will adapt himself to manipulating with such tools as these, while attempting to retain his characteristic touch, we can only surmise.

Again, take painters whose *forte* is broad effects on large and coarse canvas: how will they succeed in translating their large works on to a plate of engraving dimensions, say a reduction from a six or eight feet picture to a twenty-four inch plate, for example. Will they be able to work on a proportionately small scale and yet retain their individual touch with the means that have to be used? There is a wide difference between a portrait by a Watts on canvas and a miniature on ivory by a Cosway. Further, how will the artist, who is only used to painting on more or less coarse canvas, get on when working on a burnished metal surface? In the Herkomer-Cox specification it is mentioned that the electrotype plate may be used as it comes from the bath, and adds: "but, when the artist is familiar with the resources of the experienced engraver, the dry point may be used, or the process of etching or mezzotint may be applied, for working up the picture and producing brilliant artistic effects." From this it may fairly be assumed that the plates require working up by hand to obtain the best effects. Hence the artist who would work the new process must needs be an experienced engraver as well as painter to produce good results.

We will now turn to photogravure, which Mr. Herkomer has loudly decried. Here we take the original painting and reproduce it by photography direct to the size desired. In doing this the characteristic, and individual, touch of the painter is preserved in its integrity, and in true proportions as regards the size of the plate and painting; and not on a larger scale, as would almost necessarily be the case if the artist had to copy the original on the small scale. By orthochromatic photography the colours will be better rendered in monochrome than nine out of ten painters could do it with the differing thicknesses of paint on the burnished copper plate. We need not, however, dwell on this subject further, for we, like most who take a practical view of the matter, feel sure that, notwithstanding the way it is being boomed in certain quarters, photogravure has not anything to fear from the "New Art" process either artistically or commercially.

THE SULPHOCYANIDES AS FIXING AGENTS.

II.

On reference to the table of solubilities of the silver haloids, by Valenta, published in the Almanac, it will be seen that on the score of solvent power the sulphocyanides are far superior to hypo when we have to deal with bromide proofs, though hypo is as far ahead of the other when chloride of silver is concerned. The latter fact might be taken as explaining the imperfect fixation alluded to, were it not that, as we have already mentioned, the strength of the fixing bath and length of immersion had no effect in surmounting the difficulty; but, when an immersion of several hours produced no better effect than one of a few minutes, the cause is evidently to be traced in some other direction.

We know perfectly well what occurs in the process of fixing with hypo; the silver salt is dissolved, and forms a double hyposulphite of silver and sodium, varying in solubility according to the proportion of fixing agent present. The precise action in the case of the sulphocyanides has not been so thoroughly investigated, and, whether the change that occurs in the process of fixing is a chemical, or merely a mechanical one in which the silver salt undergoes solution without further change, we are not prepared to say, but several points in the behaviour of solutions of the silver haloids in sulphocyanide of ammonium would point to the latter. So far as the completeness, or perfection of fixing, or the permanence of the proofs fixed is concerned, it would not matter much which is the correct explanation if the silver salt remained in solution; but it apparently does not, as may be quickly recognised by fixing a bromised or bromo-iodised collodion film in sulphocyanide. We leave gelatine out of the question, on account of the powerful softening or solvent action of the sulphocyanide on that substance.

If a collodion film be immersed in a solution of sulphocyanide of any strength—it is immaterial whether it be saturated or comparatively weak, provided it is strong enough to remove the silver haloids—the plate will be fixed in the ordinary manner, that is to say, the bromide and iodide will be dissolved, and the portions of the film unacted on by light will be rendered transparent; but, if the plate then fixed be laid in a dish of water, it will be seen that the haloids are partly precipitated again, some portions being washed out into the solution, others being deposited in and on the film, giving it the appearance of having been imperfectly fixed. A second immersion in the fixing solution will remove this appearance, and, if it be a fresh and unused solution, there will probably be an end of the difficulty; but, if it be partly charged with silver from repeated use, the chances are that there will be a second though less marked deposition of the silver.

If this occur with bromide of silver, which is extremely soluble in sulphocyanide, how much more likely is it to occur when the chloride, which is the less soluble, is in question? and, if this reprecipitation occur with chloride of silver on a paper print, there is nothing to show that it has happened until the print is exposed to a strong light, when, of course, a greying of the chloride will take place over the whole surface. This, we think, fairly explains the reason why sulphocyanide proved for prints, at least, a "fixing agent that will not fix," as it was dubbed many years ago.

In its application to the fixing of negatives we are more fortunately placed in being able to recognise any considerable deposition of silver in the portions of the plate that should be clear, and so in a position to repeat the fixing if necessary. In cases where the fixing, or, rather, the subsequent washing, forms the final operation, no further trouble, perhaps, will occur, but it still remains questionable whether, under such circumstances, it is any safer to resort to intensification after fixing than when hypo is used. A very minute trace of silver in the shadows of a negative or the lights of a transparency, a trace so minute as to be practically invisible to the eye, will be quite sufficient to cause discolouration and ruin when the pyro and silver or mercury intensifiers are afterwards applied, and there is this additional disadvantage with sulphocyanide as compared with hypo, when the fixing has been "perfect," that the danger cannot be removed by any amount of washing, since the silver is present in an insoluble form. Sulphocyanide, in fact, leaves the plate in much the same condition that it would be in if insufficiently fixed with hypo.

Photography in Colours.—In the light of recent investigations this can no longer be regarded as a cry of "Wolf," but we shall need more information before being sanguine about the most recent discovery as given in some of the American papers, which state that two Chicago investigators have succeeded in discovering this photographic "philosopher's stone." Their names are given—Messrs. M. J. Steffens and J. W. MacDonnough. The former uses the Daguerreotype process, while some method of utilising glass screens is employed by the latter. The whole thing seems to be a hash up of Professor Joly's inventions.

Swiss Photographs Wanted.—We have pleasure in giving publicity to a request made through the columns of *Nature* by Léon Du Pasquier, Neuchâtel, for photographs that may assist in discovering the causes leading up to the avalanche of the glacier of l'Altels. To make clear the points referring to its cause, he writes that the Glacier Commission needs photographs taken before the disaster, even going back several years if possible. After having fruitlessly endeavonred for several months past to obtain such views, he feels sure that many photographers must have photographed l'Altels from the W. or N.W., and he asks any who have done so to send prints to him, indicating the date they were taken, at least to the month and year.

"Made in Switzerland."—This cry will, we fear, soon be as common as the more familiar label referring to Germany as the place of manufacture of goods which used to be made, and ought still to be made, in our own country, for it is certain that in the manufacture of scientific instruments the Switzers are already competing seriously with us both in quality and price. Only the other evening, when Colonel Stewart was showing his new panoramic apparatus to the Camera Club, he was asked who was the manufacturer. His reply was that it was made in Geneva, that he found that he could not get it made as he required it to be made in England, but that his wants were readily met at Geneva. The cost, too, was one-third less than the price asked by the British manufacturer. We have heard many stories of a like nature which are corroborative of Colonel Stewart's experience. In one recent case a patentee informed us that it was much cheaper to have the parts of instruments made in Switzerland, and imported over here to be put together, and to pay all the costs of the carriage, than to have the thing constructed, *ab initio*, here. It was not only cheaper, but the work was far better done. "'Tis true, and pity 'tis 'tis true."

The Röntgen Rays.—The interest in the new photography still continues unabated, and from many quarters we have accounts of successful followers in Röntgen's path. So much is this the case, and so comparatively simple does the process appear, that it seems wonderful that their remarkable properties were not made known at an earlier period. As a matter of course, there are many claimants to prior discovery; but the claim is for the same thing—with a difference. There is a fair consensus of evidence that photographic action has been brought about through opaque bodies by radiations of electric origin, but Röntgen's rays are different from all. An opinion has been expressed that the discoverer is holding something back; but results equalling his have, at any rate, been obtained by apparatus put together with no other guide than the newspaper accounts of Röntgen's work. Sparks from an ordinary Ruhmkorf's coil have been used, as also the ordinary Geissler tube, through which an actual current passes unlike the Crookes' tubes, in which the "current" can only be said to pass in the popular sense of the word, the vacuum being so nearly perfect.

We have already put on record some strange light effects produced through opaque bodies, notably M. Le Box photographing through a sheet surrounding a dark slide enclosed in a slide, no other source of light than a paraffin lamp being used; but surely a letter in last week's *Nature*, over the signature of W. Saunders, is the most remarkable contribution of the kind. "Upon a piece of board I placed a sensitive plate, on this a penny piece, with the obverse side downward, and on the penny piece a $\frac{3}{16}$ inch cedar board. The whole was exposed to the light emitted by the burning of sixteen inches of magnesium wire at a distance of six inches. An inspection of the photograph will show a distinct image of the Queen's head." What can be the use of writing this sort of thing? No mention is made of any protection against the entry of reflected light at the side, under which conditions it could be easily imagined that some indistinct impression of the coin would be visible.

Soldering Aluminium.—For such work as joining the edges of the metal in making tubes for optical work, the difficulties of soldering aluminium were long considered a great drawback to its possible future usefulness for these purposes. Improvements have been made, but, from a paper read by Mr. J. Richards before the Franklin Institute, we learn that a method has been discovered by him of reducing the soldering to a very ordinary operation. In his paper he points out how Christoffe, the goldsmith of Paris, showed that the metal could be soldered by either pure tin or pure zinc; but the discovery proved useless, for the zinc junction is brittle, will not stand working, and soon discolours, while the tin seam disintegrated, and fell to pieces in a few weeks. Other inventors recommended the use of ordinary solder, with the use of chloride of silver as a flux, which would naturally be costly, and some one has proposed this as a reason for the enormously high prices of aluminium-mounted photographic objectives.

Mr. Richards set himself the task of discovering a solder possessing the necessary characteristics: 1. It must heat, and adhere closely; 2, must not disintegrate after exposure to air; 3, have a low melting point; 4, be the same colour as aluminium, and not change colour; and finally, 5, must be cheap enough for general use. These requirements he obtained to a reasonable extent after a series of experiments, but it was discovered that, upon remelting this solder, a more fusible portion separated from the mass, and this was found to

act still better under the iron than the first-made. The composition of this was proved on analysis to be aluminium, one part each of phospher-tin and aluminium, eleven of zinc, and twenty-nine of tin, the two latter being present in the proportion given by the formula Sn_1Zn_3. He says, "The result of the investigation is before you in the specimens of soldering presented for your inspection. As practical usefulness is a fair criterion of the value of an invention, I may be permitted to mention that this solder has come largely into use in Germany, Switzerland, England, and our own country." If all that is claimed for it be true, the use of this new solder ought to lead to a cheapening of aluminium-mounted lenses, the price of which, notwithstanding the admission of the difficulty in working it in the lathe, tapping it, &c., is still very high.

ON AN IMPROVED METHOD OF COATING PAPER FOR DIRECT PIGMENT PRINTING.

In my paper on the subject of the Artigue Papier Velours, and similar methods of carbon printing without transfer, I pointed out that the preparation of such paper one's self was not unattended by difficulties. In the hands even of the most experienced, results were variable, and one was obliged to admit that it was somewhat difficult to ensure such an even coating of the paper as should give full value to the effects which one might desire to obtain in the print. A very great step in advance has been made by Monsieur Demachy, and was communicated by him to the Photographic Society of France a few weeks ago. We must be prepared, of course, to be told by scientific men that they knew all about it before, and that it is only a modification, and so on; but, although I shall use no chemical terms of unparalleled length in describing it, and although the novelty is absolutely as simple a thing as the breaking of the egg by Columbus, I have no hesitation in saying that it is entitled to all the merits of a new discovery. The simplification of former difficulties is very striking, and, indebted as we are already to Monsieur Demachy for showing us better than any others had yet done what beautiful effects could be obtained by a method which he had so far matured, we are still more indebted to him, now that he publishes gratuitously the results of his own more recent investigations—results which will go far, no doubt, towards bringing into our market direct pigment paper manufactured by our own manufacturers. I myself am personally aware that it is no mere hazard which has led to Monsieur Demachy's discovery, but that it is the result of long and patient investigation and the trial of many substances and variations.

One of the earliest to reintroduce the method of the direct coating of paper with a bichromated compound of gum and pigment was Monsieur Rouillé-Ladevèze of Tours, and a pamphlet descriptive of his process was published by him a year or two ago. He was careful in his directions to lay stress on the necessity of the pigmented mixture being of a neutral and not of an acid character; but, whether arising from this condition or not, it was difficult to obtain uniformly good results, and ease in applying the coating to the paper. The experiments of Monsieur Demachy with various colloids, alone or mixed with gum and under varying conditions of acidity, or the reverse, led him to the very simple discovery that the principal factor in the successful coating of the paper was, that the mixture should be a distinctly acid one. The procedure requires little more description or amendment of previous formulæ than may be stated as follows:—Take about equal quantities in bulk of very thick gum arabic (the common reddish kind, as thick as it can be made, may be used) and of fresh lemon juice, which homely term and substance will serve equally as well as any other. Mix well together until you get a very glutinous, soft syrup, and add bichromate of potash in solution, and the pigment to be employed, until the requisite thickness is obtained. Brush the mixture over the paper in the manner which has previously been described, making the coating even and smooth by means of a badger's-hair softener. If there is a tendency to clogging of the whites in developing, a few drops of essence of thyme (the essential oil) may be added. Those who have tried and failed with the older formula, or have succeeded only with difficulty, and with no certainty of results, will find the newer method far more easy to work, and the results immeasurably superior. The bichromate solution should not be weaker than ten per cent., for it must be remembered that it will be considerably weakened by the addition of gum and pigment. It is not pretended, of course, that the process of coating is of the press-the-button order, neither does it possess any artistic qualities of itself; but that it is a decided help and a valuable discovery will not be doubted by those who may try it.

What the action of the acid may be must be left to scientific men to determine, if they deign to notice the subject. It may be humbly suggested that it may be favourable to the production of chromic acid, but the question is one which, happily, there is not the slightest necessity for those to determine whose only object in compounding the mixture is the result which may be obtained with it from the pictorial point of view.

It may perhaps appear to be very little to crow about, so simple does the description just given appear to be; but priority of discovery is a thing so audaciously and wrongly annexed nowadays that, until evidence is brought to the contrary, we are justified, while tendering our thanks to Monsieur Demachy, in claiming for him a distinct novelty in the invention of the acid-gum process in bichromated pigment printing. By the way, is not the latter a better term than carbon printing, which would appear to be only applicable when carbon is present? It certainly is not necessarily so always.

I may perhaps be permitted to take the opportunity of replying to an article signed "C. J.," in a contemporary a few weeks back. The writer says that "the gentleman who has laboured most to introduce the Artigue method of work to the notice of photographers in this country has gone out of his way to point out what he considers an error in the text-books, wherein they say that carbon prints must be exposed (? developed) from the back, to avoid the image being washed away," &c. It may possibly be presumption on my part, but perhaps it is to myself that "C. J." alludes as "the gentleman." At any rate, I am prepared to take up the position and avow my sympathy with the sentiments expressed. I need not, perhaps, imitate the reticence of "C. J.," nor hesitate to recognise under these initials Mr. Chapman Jones. It is at least refreshing that a man of science has at length deigned to notice a discovery of such value as the Artigue method of simplified pigment printing, which has for several years been shown to be practicable. In this country, however, there appears to have been a conspiracy of silence concerning it, and it is difficult to avoid the impression that, when at last compelled to take notice of it, the object of Mr. Chapman Jones's remarks is to discount the fact that it is to Artigue, and in a lesser degree perhaps to Ladevèze and others, that we owe the discovery that what has been taught in distinct terms to be impossible is, nevertheless, to be done with the highest degree of success. Mr. Chapman Jones says that the error which I pointed out is my own, and not that of the text-books. I confess my inability to comprehend his arguments. If, for brevity, I may be allowed to give the gist only of his remarks, he says, "The fact that carbon prints *must* be transferred for development was discovered nearly forty years ago, and any tyro can prove that the facts are as stated by a few simple experiments;" and immediately after: "the other fact, that it is possible to get a chromated film so thin and even that a successful printing method can be formulated *by working wholly from the front*, is not contradictory of the first fact." It is, according to Mr. Chapman Jones, a modification only. Well, to my mind, such a statement is pure sophistry. The dictum of all text-books on carbon printing, such, for instance, as that of the Autotype Company has been, up to the latest editions, distinctly laid down. For example (page 3 of the *Autotype Manual*), "the Abbé de Laborde in France, and Burnet and Blair in England pointed out the reason for the imperfect results arrived at by Poitevin: they showed that the pigmented compound became entirely insoluble on the surface, ... *and it was clearly demonstrated that, if the pictures were to be developed at all, that could only be successfully accomplished by attacking the film on the opposite side.*" It has now been clearly demonstrated by, amongst others, MM. Artigue, Demachy, and Ladevèze that it can be successfully accomplished without attacking the film on the opposite side, and it is hardly correct, I think, to call this a modification only of the unsuccessful method. I have brought the charge of false teaching and want of knowledge on this subject

against our scientific makers of text-books, and I maintain it. Mr. Chapman Jones will hardly deny, I think, that such decided statements as I have quoted have contributed to delay the introduction into this country of the beautiful and simple non-transfer process, and to give perhaps to another country the merit of a discovery which might have been ours. As regards priority of invention, will he say when (prior to Artigue's production) he himself was first aware, from actual examples, that pigmented prints could be *successfully* developed from the front, preserving half-tones, &c.? To avoid misconception, as it is admitted that carbon prints were made in early days by exposing through the support, the claim which I make for the recent advance is the coating and subsequent development directly from the front (and, incidentally, *cold* development), and I say that, for work giving the finest detail, no one succeeded in so doing before the advent of Artigue's papier velours. It would be interesting to know also whether Mr. Chapman Jones considers that the cautioning or, rather, prohibitory clauses which I have quoted should still be promulgated in future editions of works on the subject.

I hold no brief for M. Artigue or his paper, and I am personally far more interested in the preparation oneself of paper for direct pigment printing as practised by Demachy, Ladevèze, and others. For what we call artistic work I consider this to be the most natural, the most efficient, and the most delightful to work of all printing methods. It is personal to the artist, and he is entirely free from subjection to the sphere of influence of any scientific considerations whatever.

ALFRED MASKELL.

ELECTROGRAPHY.

IN consequence of the interest occasioned by this new branch of science, I supplement my article, published in the last BRITISH JOURNAL OF PHOTOGRAPHY, with a few additional remarks.

It appears to be an anomaly to assume that the effects are produced by some hitherto undiscovered "Nodal," or X rays in the spectrum, "incapable of refraction." For the spectrum itself is a result of refraction, in which all included rays must go together. There is nothing in the phenomena that cannot be explained and demonstrated by the known laws of induction appertaining to static electricity. I cite the well-known experiment of mounting a series of discs of conducting materials, on insulated supports, in proximity to an electric machine in active operation, with intervals between them. These act reciprocally on each other with a counteracting influence, that is, if the first disc is positive, the next will be negative, and so on throughout the series; so that every substance, according to its material, placed within the sphere of electric induction, will not be passive, but, in a contrary state, either positive or negative, with neighbouring ones, and the approximated discs will be more or less affected by differences of configuration, irregularities, or conductibilities of parts of the surfaces.

It has been pertinently asked by a correspondent if glass, as stated, is "opaque" to these assumed + X rays, why the radiations from an electric vacuum tube should be available? But even glass is permeable, and subject to the influence, for, if a pane be placed in the field of induction, one side becomes positive and the other negative, constituting, in fact, what is known as the "Franklin pane." For this reason, an intervening pane in a state of electric tension may materially retard the passage to other bodies, but yet itself is affected thereby.

That feeble charges of electricity will act on sensitised photographic paper is well demonstrated by the now disused ozometer, wherein a band of sensitised paper, screened from the light, is traversed by a weather recorder or clock movement, giving a continuous dark streak of varying intensity, according to the electric condition of the atmosphere. Sometimes this would be so highly-charged as to give an interval of comparatively surprising intensity for a short period.

About thirty-five years ago a paper from me was published in the *Quarterly Journal of Microscopical Science* on obtaining photographs of objects with the microscope. For artificial light I found it of advantage to get the illuminant as close beneath the object as possible; of course I could not effect this by any ordinary lamp, so I had recourse to the sparks from an ordinary frictional electric machine, the separated terminals almost touching the object. I stated that an intermittent or flashing light was quite as effective as a continuous one; but what surprised me was that structure was brought out in parts of objects so nearly opaque as scarcely to be discernible under the instrument as ordinarily used. I exhibited specimens at the Microscopic Society at the time. I attribute this peculiar distinctiveness to the intense actinic power of the electric spark, but I am now disposed to alter my opinion. It may be remarked that the objects were mounted in Canada balsam, and were therefore insulated, and it yet remains to be seen how far insulation of the subject will effect or enhance the results in the practice of electrography.

As to the source of the electric induction, nothing can be more handy than the Wimshurst machine. My own never gets out of order or fails in energy, but it is always ready for action without any preparation.

In reference to these investigations, as far as experiments have carried them, may it not be inferred that, in the total absence of all light, certain electric radiations, analogous to induced influences, take place between differently constituted bodies or substances that will, like light, exert a chemical change on sensitised surfaces? Experiment has already gone some way towards proving this.

F. H. WENHAM.

FOREIGN NEWS AND NOTES.

Artificial Indiarubber.—In these days of artificially prepared products of all kinds, it is not surprising to hear that Indiarubber can now be made by the action of bromo-nitro-toluol on nitrocellulose, and that the elasticity and properties of the new substance can be altered by alteration of the proportions of the ingredients.

The Production of Indigo by Light.—Professor Engler and Doraut, of Karlsruhe, have discovered that an ethereal solution of benzyliden-orthonitroaceto-phenone when allowed to evaporate at ordinary temperatures, deposits colourless neroles, which are converted into indigo blue. The special interest attaching to this is, that the colourless crystals, although remaining colourless under red glass, become greenish-yellow under yellow, and deep indigo blue under blue glass.

Photographic Journalism in Russia.—We believe that hitherto there has been a grand opening for some enterprising English photographic journalist to give play to his budding genius in Russia, for we do not think there has been a Russian photographic journal, but now we have received the first number of a monthly photographic review, which is well printed, and, doubtless, contains interesting matter; in fact, we are sure it does, because we note some extracts have been made from our columns, and, further, there is a long communication from A. B. Bapnekpe, or, as we usually call him, Mr. Leon Warnerke. After reading the journal through most carefully, we came to the conclusion that photography must be flourishing to be able to support a monthly of fifty pages of literary matter, besides two full-page half-tone illustrations. It is published in Mockba or Moscow, and edited by Pierre Preobrajensky.

Some New Ideas on Lenses.—In the *Photographisches Archiv*, Professor Zenger points out the possibility of making anastigmatic-apochromatic lenses with far fewer elements than are at present employed in some of the newer lenses; in fact, that they may be constructed of two glasses only, and "it is possible to correct all the faults of the single lens, such as chromatic and spherical aberrations, distortion, and astigmatism with two lenses of different refractive glass, by suitable choice of curve and substance, as in the human eye, and thus to obtain a higher degree of apochromatism than can be obtained by use of the newest of the Jena glasses." As the Professor points out, such lenses should be much cheaper than the best lenses of the present day, whilst being equally good in working powers. His final conclusion seems to point to a construction of plano-convex and plano-concave lenses, as in the Concentric.

The Wave-length of Light as a Unit of Measure of Length.—Two assistants of the Smithsonian Institute, Michelson and Morley, have been experimenting in conjunction with M. Benoit,

in Paris, to determine, if possible, the length of the standard metre by means of the wave-length of monochromatic light. Their first attempts with the well-known sodium or D lines showed that these were not sufficiently monochromatic, but that the red cadmium line was. After several months' work, the mean of two absolutely independent experiments proved that the length of the standard metre was 1,553,163·5 wave-lengths.

The Use of Urea in Gelatino-bromide Emulsions.—M. Pierre Scheers contributes to the current issue of the *Bulletin Belge* an article describing his experiments with urea as an addition to bromide emulsions. He points out that the fineness of grain of the silver bromide is dependent on several factors, such as, the concentrations of the solutions, the quantity of the gelatine, the degree of heat, and the method of precipitation. A fine-grained but slow emulsion usually appears of a deep yellow by transmitted light, and it is desirable to transform this colour into blue or violet, which transformation is usually accompanied by an increase of grain. The transformation or ripening is usually effected by heat, or ammonia, both methods having considerable disadvantages, which do not accompany the use of urea, which is slowly decomposed into ammonia and carbonic acid. A definite quantity of urea—which, by the bye, is not stated by the author—is added to the emulsion, together with the ferment necessary to produce this decomposition. This ferment is obtained from urine allowed to stand and ferment, and, by the addition of alcohol, some substance, assumed to be of the nature of diastose, is precipitated, which can be filtered out and kept in a bottle, and mixed in small quantities with the urea before adding to the emulsion. This, it is said, produces an extremely fine-grained, rapid emulsion.

Relative Permanence of Prints.—Vogel classifies the various printing methods, according to their permanency, as follows:—(1) Prints on gelatino and collodio-chloride paper, toned in a combined bath, fade very quickly; (2) the same papers and albumenised, treated with separate baths, keep better; (3) developed silver prints are still more permanent; and (4) the carbon process gives prints which are chemically inalterable; whilst (5) the most durable prints of all are given by the platinotype process.

Acetylene.—Le Roy states that a kilogramme of calcium carbide yields 355 litres of acetylene, and that this gas possesses an illuminating power fifteen times greater than ordinary gas. He makes it in a steel bottle, enamelled inside, some calcium carbide being placed in a leaden vessel in the bottle, and the necessary quantity of water is also enclosed in a thin glass tube; the bottle is closed, the water tube broken by shaking, and the acetylene thus generated compresses itself. To obviate any danger from the heat evolved, the bottle is placed in cold water and the quantity of calcium carbide carefully calculated. A Wiesnegg's Bunsen burner is used, and, if oxygen instead of air is used with the acetylene, a much more brilliant light is obtained—in fact, stronger than the limelight.

Destruction of the Latent Image.—In continuation of his experiments on Lippmann's process of heliochromy, Dr. Neuhuss finds that, if the exposed plate is left for three days in contact with the mercury, the latent image is destroyed, and that, if the plate had stood in contact with the mercury for an hour and was then kept in the dark for four days, no image could be developed.

Two new Actinometers.—C. Conquerant of Paris has introduced two new exposure meters which consist of wedges of smoked glass; one is used in contact with the ground glass of the camera and, is therefore much on the same principle as Decoudun's, and obviously gauges the exposure by the visual rays; the other is used in contact with a piece of thin porcelain or opal, and is used to measure the amount of contrast in the subject as a guide to development.

Lactate of Silver Plates.—Guilleminot of Paris has introduced lantern plates prepared with silver lactate, which with a metol carbonate developer are said to give excellent results as regards vigour, clearness, and tones. The light-sensitiveness of silver lactate was discovered by Pelouze and Guy-Lussac in 1833, and it was used by Cooper in collodion emulsion (THE BRITISH JOURNAL OF PHOTOGRAPHY, 1871, p. 187). In printing out, its sensitiveness is stated by Marktanner-Turneretscher to be eighteen as compared with 100 for silver chloride.

Three-colour Printing.—As light filters or screens for three-colour work, the following solutions are recommended, but the value of the same is doubtful, in that neither the plates nor thickness of solution are indicated.

For the violet screen,

Concentrated cupric chloride solution	7 parts.
Distilled water	17 ,,
Ammonia	5 ,,

Filter and add

Concentrated solution of methyl-violet B ..	3 parts.
Concentrated solution of fuchsin S.	5 ,,

For the orange screen,

Concentrated solution of cobalt chloride	15 parts.
Distilled water	35 ,,
5 per cent. solution of ammonium bichromate	25 ,,
Ammonia .....2 to 3	,,

Filter before use.

For the green screen

Solution of nickel sulphate.

These formulæ are somewhat on a par with those given by a contemporary where we are told to "dissolve a bit of resin the size of a hazel nut."

OAKLEY'S ANTIHALATION SUBSTRATUM.

MR. C. F. OAKLEY, in describing his improvements in the manufacture of photographic plates and films, says that for the purpose of preventing halation it has been proposed at various times during the last six or eight years to coat the glass plate, film, or other support for the sensitive emulsion with a layer or substratum below the sensitive emulsion, this layer or substratum containing a colouring matter which renders it non-actinic, the said colouring matter subsequently disappearing during the development or fixing. But these coloured substrata have failed to answer in practice, because the colouring matters which they contain are of such a nature that they become, to a great extent, taken up by the superposed coating of emulsion, the sensitiveness of which is consequently seriously impaired and sometimes practically destroyed.

It has also been proposed, with the object of preventing halation, to coat the glass plates, or other supports, with two or more coats of emulsion of graduated degrees of sensitiveness.

"Now, the object of my invention is to cover the glass plate, or other support, with a layer or substratum coloured with such a material and in such a manner that the colouring matter will not be subsequently taken up by the sensitive emulsion applied to the plate over the substratum, the sensitiveness of the emulsion therefore not being affected.

"My invention consists in the manufacture of photographic plates and films by first coating the glass plate, or other support, with a solution of gelatine or other suitable non-sensitive material, then immersing the plate, preferably when dry, for a sufficient length of time, say from two to five minutes, more or less, in a colouring and hardening solution, then, after washing the plate and allowing it to dry, coating it with a sensitive emulsion. The coating of sensitive emulsion should be allowed to dry in a dark room. The colouring and hardening solution must be one that will not only colour the layer of gelatine and render it non-actinic by entering into the substance of same, but also produce a reaction which has the effect of oxidising and hardening the gelatine, and rendering it practically insoluble. Consequently the colouring matter is prevented from being taken up by the sensitive emulsion subsequently applied. The solution preferably employed for the purpose is permanganate of potass, and a suitable strength is obtained by adding about one ounce of the permanganate to one gallon of water.

"The colour in the non-sensitive substratum disappears during the development when developers such as hydroquinone are employed, or in the fixing bath when this contains sulphite of soda and acid."

WELLINGTON'S IMPROVEMENTS IN THE MANUFACTURE OF STRIPPING FILMS.

MR. J. B. B. WELLINGTON, in describing his improvements in the manufacture of stripping films, says the invention has for its purpose to provide a film of gelatine, which is supported during exposure upon a backing of paper, cardboard, or the like, from which backing it is stripped prior to the process of printing.

Hitherto stripping films have been formed by interposing between an insoluble gelatine and a paper backing a layer of soluble gelatine, which was, after development and prior to the process of printing, dissolved by means of hot water, thus releasing the negative from its temporary support. In films of this class the insoluble gelatine was so thin that it was necessary to transfer it to another permanent transparent support, this transference forming a necessary part of the process. Stripping films of this kind were found to be unsatisfactory in various respects, and the process is now no longer to be met with in practice.

"In stripping films manufactured according to my invention the disadvantages hitherto obtaining are overcome. The stripping is effected without the use of hot baths or special treatment of any kind, and it is not necessary to transfer the stripped film to any other support

"In carrying my invention into effect I coat upon one or both sides of any suitable paper, as, for instance, upon the well-known photographic papers, and also those coated with baryta, whether matt or calendered, a substratum containing a suitable proportion of any gum or resin dissolved in any of the well-known solvents which are in general use for this purpose. In practice I have found that good results may be obtained with mastic, and this in varying proportions, or with other gums and resins, as, for instance, damar, copal, and their congeners, but I prefer to use gum sandarac or gum copal. The thickness of the solution of these gums is, in like manner, capable of considerable variation, and will depend in great measure upon the means which are adopted for coating the paper. For instance, if the paper be coated by immersion in a trough, a solution of one part of gum sandarac or gum copal and ten parts of methylated spirit or other solvent will be found to answer well. The gum solution may, if desired, be stained with some non-actinic colour in order to prevent the transmission of light through the film and to diminish halation.

"Having thus prepared my paper backing by coating it with a substratum of gum, and permitted it to dry, I proceed to coat thereupon the layer of gelatine which is destined to form the body of the film itself. This body I form of gelatine, which I preferably render insoluble by the addition thereto, immediately prior to coating, of a suitable proportion of soda alum, chrome alum, or any of those well-known chemicals which have the property of rendering gelatine insoluble when dry. I coat the gelatine upon the gummed paper backing in sufficient thickness to give me, when dried and stripped from the gummed paper, a film of sufficient substance to serve as the support of a negative. In practice, I prefer to make the gelatine so thick that the resulting film, together with the emulsion spread upon it, measures from 2000ths to 10,000ths of an inch in thickness when dry, in order that it may not be necessary to transfer the film to another support. If it be desired, the paper backing may be coated with the gelatine upon both sides, the coating upon the back in such case having for its purpose to prevent the warping and cockling of the entire support through change of temperature and hygrometric conditions. When the gelatine is dry, I coat upon it the sensitive emulsion in the manner well known to those skilled in the art. This process completes the manufacture of the film.

"If desired, the silver salts may be emulsified with the gelatine used to form the body film, in which case the body film and sensitive surface are produced at one and the same operation, thus avoiding the loss of time involved in the double process and the intermediate drying operation.

"I expose my improved film while still in contact with the backing of gummed paper upon which it is formed, this backing giving body and rigidity to the film, which is advantageous. In like manner I preferably effect the process of development, fixing, and washing upon the paper backing. When the washing is complete, or at any stage of the process after exposure of the film, I separate or strip the body film of gelatine, together with the emulsion coating upon it, by pulling off the backing of gummed paper, the function of the gummed substratum, in which lies the essence of my invention, being to facilitate the stripping process. Having thus separated the negative with its permanent support, I preferably squeegee this upon a ferrotype plate, sheet of glass polished by means of French chalk, or talc, or with wax, or other similar plane and polished surface, upon which it is permitted to dry, and from which it derives a flat and polished surface. The negative may be squeegeed with either surface in contact with the polished plate. Should it be desired to remove any grain or matt appearance of the paper backing which may appear upon the gelatine body, this side may be placed for this purpose in contact with the polished plate. When the negative becomes thoroughly dry, it is peeled from the polished surface, and is then ready for printing."

NOTES FROM THE WEST OF SCOTLAND.

In Glasgow considerable interest has recently been taken in the utilising of house gas for the purpose of lighting studios for portraiture. On the invitation of Mr. Verel, of the Albion Albumenising Company during the last ten days or so, quite a large number of professional photographers in and around Glasgow have had an opportunity of inspecting and working a new lamp specially designed for portraiture; the gas burners are on the incandescent principle, but there seems to be a distinct improvement in the quality of the light over the earlier forms of such a method of lighting; this may probably be caused by an improved mantle or shield which we understand has been adapted to the lamp; in any case a beautifully pure white light is provided, the mantles of the burners diffusing the light in a most effective manner.

The arrangements for altering the elevations and position of the lamp are simplicity itself, the slightest touch being sufficient to raise or lower the illuminating portions into any desired position.

In candle power, we should say that the lamp, when burning at its best, with a full supply of gas, is considerably over a thousand candle power, but even with this there is no overheating of the studio, and it is claimed that the cost of working the same does not exceed a few pence per hour.

We had the pleasure of making a few exposures with the aid of the new lamp, and were surprised at the shortness of time needed, a few seconds only being required to yield excellent negatives.

Much satisfaction has been expressed by those who have had an opportunity of inspecting and working the new lamp, and it would appear as if a distinct advance had been made in the direction of artificial lighting of studios by means of house gas.

The prospects of Glasgow having another International Exhibition in 1897 continue to brighten every day, and before long it is probable that a committee will be formed to further the scheme.

The Inquirer.

*** *In this column we shall, from time to time, print questions that may be addressed to individual contributors to our pages, or such as are sent to us with the view of eliciting information from a variety of sources. We invite the co-operation of our readers in rendering this feature of the* JOURNAL *useful and instructive.*

ACETYLENE GENERATOR (To MR. THOMPSON).—"The acetylene generator I described was simply an old oxygen generator apparatus which I had had by me for years, and was utilised for this purpose by suspending in it the flower pot to hold the C_2C_2. A diagram would not make it any clearer, and I do not claim it as the best form possible if you are going to construct one specially."—E. BANKS.

COLLODION EMULSION (To MR. J. HAMPTON).—"In an article subsequent to the one Mr. Hampton has been working from, I pointed out that with many samples of the new methylated spirit an organic salt of silver and chromium was found, and which was not discharged by the cadmium bromide. The simplest plan in that case is to add the bromide first, until all the free nitrate of silver is converted into bromide, and then add a drop of saturated solution of bichrome. The emulsion should be pure white or nearly so, and not grey."—E. BANKS.

ACETYLENE (To E. W. B.)—"I wrote of acetylene not as a possible rival to ordinary gas, but as a pure, brilliant, and very actinic light for photographic purposes, and which was so safely and easily produced with simple appliances. For this purpose, ordinary gas is not in it, and even the incandescent gas is not equal to acetylene, on account of its large area of flame. If you place a stop, say of $\frac{3}{4}$ inch diameter, before the incandescent gas, and also the acetylene, the difference is much in favour of the latter."—E. BANKS.

Our Editorial Table.

RECEIVED:—THE NEW LIGHT (a series of illustrated articles descriptive of experiments with the X rays), and TABLES OF CONJUGATE FOCI, by J. R. Gotz (Second Edition). Both these are published by Messrs. Dawbarn & Ward, Farringdon-avenue, E.C.

THOMAS'S A1 PLATES.

R. W. Thomas & Co., Thornton Heath.

THIS is a new plate, claimed by the makers to possess extreme fineness of grain with great speed. We readily testify to the fact that both claims are well grounded, our trials of the plates fully substantiating them. In the present demand for plates of extreme rapidity, the A1 plates should achieve marked popularity. Not only are the A1 plates very rapid, and fine in grain, but they resist fog in development to a notable degree—a point upon which many modern makers of extremely rapid plates are to be congratulated. We developed the A1 plates with Thomas's Universal developer—an

excellent developer—in one solution, which we can highly recommend. The following pyro-ammonia developer is also given by the makers :—

PYRO STOCK SOLUTION.

Sodium sulphite	3 ounces.
Ammonium bromide	½ ounce.
Citric acid	¼ „
To be dissolved in boiling water made up to	10 ounces.
When quite cold add pyrogallic acid	1 ounce.

AMMONIA STOCK SOLUTION.

Liquor ammoniæ ·880	1 ounce.
Distilled or boiled water to make	10 ounces.

(The above solutions will keep good for a long time if well stoppered.)

No. 1 SOLUTION.

Pyro stock solution	2 ounces.
Water to make	20 „

No. 2 SOLUTION.

Ammonia stock solution	2 ounces.
Water to make	20 „

For *normal* exposures use equal parts of Nos. 1 and 2; for under-exposure increase the No. 2; for over-exposure reduce the quantity of No. 2 solution.

For the convenience of those who wish to make up small quantities the following instructions are given :—

Pyro stock solution	1 drachm.
Ammonia stock solution	1 „
Water	2½ ounces.

To be modified for under or over-exposure as above directed.

News and Notes.

MR. THOMAS H. KING, M.P.S., of the Amersham Pharmacy, Market-square, Amersham, writes: "Kindly intimate that I have a dark room for use of visitors."

A CENTRAL NEWS telegram states that Mr. Thomas A. Edison is at present specially devoting himself to work with Professor Röntgen's light, and will shortly attempt to photograph the human brain.

MR. T. A. SCOTTON, Hon. Secretary of the Derby Photographic Society, writes: "Will you kindly inform your readers that I have removed from 9, Church-street, to 11, Pear Tree-road, Derby, and oblige."

WE are informed that the Marquess of Londonderry has consented to open the Exhibition of the South London Photographic Society, to be held at the Public Baths, Church-street, Camberwell, on March 2, 1896, at seven p.m. The Exhibition will continue open for the remainder of the week.

THE PHOTOGRAPHIC CLUB.—The next weekly meeting of the Club will be held in the Club-room at Anderton's Hotel, Fleet-street, E.C., at eight o'clock, on Wednesday evening, February 19. Mr. E. J. Wall will read a paper, entitled *The Composition of the Negative Image and its Relation to Speed Readings and Printing Qualities.*

MR. J. EPSTEIN, of 33, Broad-street, Bristol, has received an intimation that the highest award has been granted to him of a silver medal for his show of picture-frame mouldings and mounts at the National Trades and Industrial Exhibition held at Glasgow. This makes four silver medals within the last two years Mr. Epstein has received.

AN ALARM OF FIRE.—An alarm of fire, which, fortunately, proved groundless, occurred in Bournemouth last week. The South Coast Photographic Supply Association have recently introduced a very powerful flashlight for the purposes of photographic enlarging and copying. On the occasion of its first being put into use, the flash was so vivid and so unlike anything seen in the neighbourhood before that the brigade were immediately called out, and in less than five minutes uniformed and helmeted firemen were on the premises, only to find that their services were not required.

ACETYLENE EXPLOSION AND FIRE.—In New Haven, Conn., January 21, an explosion and fire occurred, by which three men were killed and a building destroyed, on account of experiments with acetylene, the exact nature of which and the especial cause of the accident cannot be accurately determined, as the apparatus was wrecked, several of the participants badly burned, and one killed. On the third floor of a four-story brick building was the shop of Frank P. Phlegar, a machine jobber, who was said to be experimenting upon a regulator to control the delivery of gas from steel cylinders, about six inches in diameter by four feet long, in which liquefied acetylene was kept, the pressure of which, at 66° to 70° Fahr., according to Lewes and Shuckert, would be about 600 pounds per square inch. It was known that, when the explosion occurred, seven men were standing about the apparatus, of whom one was killed, and all the others badly burned and injured. A second explosion soon followed the first, the surrounding structures being badly shaken up, and flames enveloping the building, which was so quickly destroyed by the fire that two other occupants were burned to death.

UNDER the chairmanship of the President (Mr. Leslie Selby), the annual dinner of the West London Photographic Society was held last Friday at the Frascati Restaurant. The toast list included "Success to the West London Photographic Society," admirably given by Mr. W. A. Brown; "The Officers," for which Mr. James Stein (Hon. Secretary) replied; "The Visitors," given by Mr. Wilson, and responded to by Mr. Bedding; "The Chairman," proposed by Mr. Lamley. An enjoyable musical entertainment and a capital dinner contributed to the pleasure of the members and their guests.

CAMERA-PROOF DRESSES.—A facetious writer, referring to the new photography, says: "It is said that the ordinary feminine wearing apparel will be powerless to prevent the camera from taking any picture the operator chooses, and, if the principle is carried out in snap-shot cameras, we may expect all sorts of awkward complications." The same writer has been told that the only material which will baffle the camera of the future is satin, so that ladies "who wish to preserve a certain degree of privacy in their walks abroad will do well to provide themselves with a complete suit of armour manufactured of satin." Further, the writer goes on to say that he has already heard of several dresses being described as "camera-proof."

FOR the purpose of rendering material assistance to a very old photographer (Mr. Henry Reynolds) at a time of serious illness, a smoking concert is to be held at the Champion Hotel, Aldersgate-street, on Friday, March 6. Mr. Reynolds has had a long and honourable association with photography. In the year 1860 he accompanied Mr. Warren de la Rue to Spain for the purpose of taking a series of views of the total solar eclipse, on July 18, at Rivabellosa, near Miranda de Ebro. The party also included Mr. Beckley, of Kew Observatory, Mr. Downes, and Mr. E. Beck. The extraordinary results then obtained formed the subject of Mr. Warren de la Rue's Bakerian Lecture, read April 10, 1862. He photographed the first contingent of invalid troops arriving from the Crimea, and was engaged in making the first series of views of the Abbeys of Yorkshire for the then eminent firm of Messrs. De la Motte & Cundall, subsequently the views of the Manchester Fine Art Exhibition of 1867, and, for the late Mr. Francis Bedford, his series of North and South Wales, Warwickshire, Gloucestershire, &c. Next went to Spain with Mr. Warren de la Rue, the astronomer, to do the photographic work of the eclipse, sun spots (enlarged) and lunar observations, at his observatory, as also spectroscopic work to determine red flames. Later proceeded to India, Nicobar Islands. He had the training of officers at Greenwich Observatory for the transit of Venus, assisting Mr. De la Rue in his researches in electricity with vacuum tubes, and more recently with the London Stereoscopic Company, and working in the British Museum, photographing antiquities, the Portland vase, Elgin marbles, &c. The Hon. Secretary of the concert is Mr. S. Clark, London Stereoscopic Company, 54, Cheapside, and he will be happy to supply tickets, which are 1s. each.

THE Annual Exhibition of Lantern Slides, under the auspices of the Leeds Photographic Society, was given on Thursday evening, the 6th inst., in the Albert Hall, and attracted a large attendance. About 220 slides were shown by the electric light. The Exhibition represented the work of the following members of the Society: Messrs. G. Bingley, J. H. Walker, A. Naylor, H. P. Atkinson, J. A. Moxon, J. Taylor, A. Nicholson, C. H. R. Pickard, Thomas Butterworth, H. C. Watson, A. C. Beilby, A. W. Atkinson, and Miss S. Cliff. The description of the views, all of which were very beautiful, and were much appreciated, was given by Mr. G. Bingley. In the early part of the Exhibition a number of slides, illustrating the new photography, prepared by Mr. F. W. Branson, were shown, as well as a slide showing the skeleton of the hand seen through the flesh, prepared by Mr. C. Swinton, of London, kindly lent for the occasion by Mr. B. A. Burrell. The slides represented several parts of Great Britain, the chief contributor being Mr. Godfrey Bingley, who conducted us first into Scotland, and, in the second part of the programme, into the Lake District, explaining, as he went along, many objects of geological interest. Mr. J. H. Walker's slides were, many of them, of architectural and historical interest. A batch of athletic subjects was shown by Mr. Moxon, flower studies by A. C. Beilby, and several figure transparencies by the remainder of the exhibitors, Mr. James Taylor showing, in addition, excellent work done in Jersey. Mr. Bingley announced that Mr. Branson had arranged, under the auspices of the Leeds Photographic Society, to give a lecture, with practical demonstrations, on the new photography in the Philosophical Hall, on Friday, the 14th inst. It was also announced that the Photographic Convention of the United Kingdom will hold its annual meetings in Leeds from July 13 to July 18. The Society were again indebted to Mr. F. J. Borland for making the electric arc light, and to Mr. A. A. Pearson for assistance with the lantern.

Patent News.

THE following applications for Patents were made between January 27 and February 1, 1896 :—

CAMERAS.—No. 1891. "Improvements in Cameras and Accessories therefor." C. E. PECZENIK.

CAMERAS.—No. 1907. "Improvements in Photographic Cameras." E. H. P. HUMPHREYS.

PHOTOGRAPH FRAMES.—No. 1916. "Improvement in Frames for inserting Photographs, Pictures, Prints, and alike therein." G. BUTES.

HAND CAMERAS.—No. 1933. "Improvements in Magazine Cameras with Screen Focussing Arrangement." J. W. SMITH and F. EVELEIGH.

SQUEEGEE ROLLER.—No. 1945. "An Improved Squeegee Roller for Photographic Mounting." J. HARKNESS.

CAMERAS.—No. 1957. "Improvements in or connected with Photographic Cameras." T. P. BROWN.

CAMERA STAND.—No. 1964. "Portable Camera Stand and Cycle Attachment." J. RUSSELL.

CAMERAS.—No. 2016. "Improvements connected with Photographic Cameras." D. H. T. PEPLOE.

DARK ROOMS.—No. 2117. "Improvements in or appertaining to Dark Chambers for Photographic Purposes." Communicated by H. Hofmann. G. C. DYMOND.

DEVELOPING TRAY.—No. 2165. "An Improved Tray or Dish for Photographic or other Purposes." J. AIRS.

PHOTO-MECHANICAL WORK.—No. 2359. "Improvements in or relating to Photo-mechanical Reproductions." C. F. E. FENSKE.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK

February.	Name of Society.	Subject
17	Leeds Photo. Society	*Stereoscopy.* W. I. Chadwick.
17	North Middlesex	*Development.* H. Smith.
17	Richmond	*Carbon Printing.* The Autotype Company.
17	South London	*Mounting and Framing.* J. C. S. Mummery.
18	Birmingham Photo. Society	Conversazione.
18	Brixton and Clapham	*Stereoscopic Photography.* J. Gunston.
18	Gospel Oak	*Exposure.* A. E. Morton.
18	Hackney	*A Day on Dartmoor.* G. J. Avent.
18	North Surrey	Making of Enlargements Practically Demonstrated. A. Downes.
19	Ashton-under-Lyne	*A Visit to a Spanish Bull Fight.* J. T. Lees.
19	Borough Polytechnic	Lantern-slide Making by Members.
19	Croydon Camera Club	Lantern Night.
19	Leytonstone	*How to Make Lantern Slides by Reduction.* C. A. Russell.
19	Photographic Club	*The Composition of the Negative Image and its Relations to Speed-readings and Printing Qualities.* E. J. Wall.
19	Southport	Query Night.
20	Bradford	Prize Slides.
20	Ealing	*Composition: Different Methods of Retouching.* J. T. Fairs.
20	Leeds Camera Club	*Photo-ceramics.* P. Elliff.
20	Liverpool Amateur	Demonstration on Platinum Toning of Gelatino-chloride Paper. Dr. J. W. Ellis.
20	London and Provincial	*The Kinetoscope.* Birt Acres.
20	Oldham	*Printing and Toning.* J. Brooks.
21	Birkenhead Photo. Asso.	Demonstration.
21	Croydon Microscopical	Demonstration of Anti-halation Plates. C. F. Oakley.

ROYAL PHOTOGRAPHIC SOCIETY.

FEBRUARY 11,—Annual Meeting,—Captain W. de W. Abney, C.B., in the chair.

The nominations of four new members were read, six new members were elected, and it was announced that the following had been admitted as Fellows:—Messrs. F. W. Edwards, Hall Edwards, J. H. Coath, Court Cole, and C. E. Hearson.

THE PROGRESS MEDAL.

The CHAIRMAN, in presenting the progress medal to Mr. T. R. Dallmeyer for his invention of the tele-photographic lens, said this medal was one of those distinctions which it was the aim of all who were working in the best interests of photography to gain, and in all the list of those who had already obtained it no one had secured it more honourably or by greater skill than the present recipient, who had placed in the hands of scientific men a remarkable new power which would, doubtless, in the future, bring forth fruit to the advantage both of science and of art.

Mr. T. R. DALLMEYER suitably acknowledged the presentation.

THE ANNUAL REPORT.

The Annual Report of the Council, together with the balance-sheet, was taken as read.

The report and balance-sheet were adopted without discussion, and, upon the motion of Mr. F. W. Hindley, a vote of thanks was passed to the President, the Council, the Auditors, and the Scrutineers.

Mr. J. W. WILSON then read the report of the Scrutineers, from which it appeared that the result of the voting for the new Council was as follows:—*President:* Captain W. de W. Abney, C.B., R.E., &c.—*Vice-Presidents:* The Earl of Crawford, Sir Henry Trueman Wood, M.A., and Messrs. H. Chapman Jones and T. R. Dallmeyer.—*Council:* Messrs. Thomas Bedding, Thomas Bolas, F. A. Bridge, James Cadett, F. P. Cembrano, jun., E Clifton, A. Cowan, W. E. Debenham, W. England, Colonel J. Gale, T. C. Hepworth, F. Hollyer, A. Mackie, J. A. Sinclair, J. Spiller, J. W. Swan, E. J. Wall, L. Warnerke, Paul L. Waterlow, and Horace Wilmer.—*Treasurer:* Mr. G. Scamell.

THE NEW SHADOW PHOTOGRAPHY.

The PRESIDENT, at the conclusion of the formal business of the Annual Meeting, called upon Mr. A. A. Campbell Swinton, who had promised to make a communication, with experimental illustrations, upon this subject, remarking that he objected to the use of the word "photography" in that connexion, and would prefer to use the term "shadow electrography."

Mr. SWINTON said at the outset that he was not a photographer, but an electrician, and that was probably the reason why he was present, for the difficulties attendant upon "the new photography" were chiefly electrical difficulties, and he therefore proposed to confine himself more especially to the electrical side of the question. He first showed the sparking of a Rhumkorff induction coil, then the same spark in a glass bulb, and afterwards the difference in the effect when the air had been exhausted from the bulb, the spark then appearing as two luminous rings. For the purpose under consideration, he said, it was necessary to employ tubes with far higher vacua than the ordinary Geissler's tubes, of which he showed several specimens. The difference between a Geissler's tube and a Crookes' radiant matter tube was, that, whereas in the former the luminosity was due to the gas contained in the tube, and took place throughout the whole of the tube, in the latter the luminosity was due to the cathode rays, and took place, not throughout the residual gas, but only at certain points, a peculiar point about these cathode rays being that they could be deflected by a magnet, which was a strong argument in favour of their being electrified particles of matter. One of the peculiarities of the Röntgen rays was, that they were unaffected by a magnet after leaving the glass, and this had also been determined by Professor Oliver Lodge, and they were incapable of reflection except to a very small degree. For producing photographic images by means of these radiations, it was very important to use tubes of the right description, and this depended to some extent upon the source of energy that was employed. If suitable tubes could be obtained, he thought the Tesla coil would yield the best results, as with it the exposure could be largely reduced. He had been inundated with inquiries as to where the necessary apparatus could be obtained, and therefore mentioned that suitable tubes were sold by A. E. Cossor, 67, Farringdon-road, H. Henderson, 70, Finsbury-pavement, and Poths, 3, Creechurch-lane, Leadenhall-street. Mr. Swinton then demonstrated the process. Six dry plates cut to lantern size were placed on the table, each being contained in a double envelope of black paper, and upon them were laid purses, pencils, and other small articles, at a distance of about eight inches from the bottom of the tube. An exposure was given of three minutes, by illuminating the tube for twelve periods of fifteen seconds with fifteen seconds' rest between each to prevent overheating and fracture of the glass, and the results upon development were shown in the lantern, and were in every case quite successful. An attempt was also made to obtain a "shadowgraph" of the hand of Mr. Fred Marsh, a Fellow of the Society, one of whose fingers had been crushed, but for some reason which was not explained this was unsuccessful. Mr. Swinton concluded his demonstration by saying that he and his colleague, Mr. Stanton, had been devoting their attention specially to the reduction of the necessary period of exposure, as, if the discovery was to be of any use in medicine and surgery, it was of the greatest importance that the exposure should be short, and he showed a representation of a human foot which had been secured in fifty-five seconds.

A large number of examples were exhibited by Mr. Swinton and Mr. Gifford, as also a series of new lantern slides by Messrs. Newton.

Mr. J. W. GIFFORD said that, in the course of his experiments, he exposed without pausing, giving a continuous exposure, and had not broken any tubes. He had experimented with an aluminium window to the tube, and found the advantage over glass was so small that it was not worth while to take the trouble and risk of making an aluminium tube, as had been suggested. He asked whether Mr. Swinton had noticed any difference between rapid and slow plates in this connexion. In his own case he found that there was no apparent difference in the time of exposure, whether the plates were "rapid" or "slow," and comparatively slow plates gave more plucky negatives.

Mr. SWINTON had only used two kinds of plates, and those not in such a manner as to form any opinion as to their speed.

Mr. SEBASTIAN DAVIS suggested that, for making these investigations, plates should be specially prepared, so that there might be definite knowledge as to their composition.

Mr. GIFFORD thought that no one had yet photographed the human head by the Röntgen rays, and, as a great deal had lately been said upon the subject, he had, as an experiment, attempted to obtain a photograph of the contents of an incubated egg, and he exhibited the result. The network of blood vessels was dimly discernible, but there was nothing else, and, as the human brain was surrounded by a bony envelope, he did not think it could be photographed. He had observed one effect which he was quite unable to explain, a piece of brass tube was placed in contact with a plate, and produced a white place on the negative, but, when the tube was outside the plate box, and not in contact with the film, a black ring resulted. This seemed to point to some sort of attraction of the rays by the tube, or to a reflection from its sides.

Dr. GLOVER LYON said it had occurred to him that, as the microbes of disease were killed by sunlight, they might possibly be killed by the Röntgen rays, and he had made experiments in that direction. It was a very fascinating idea that the germs of consumption might be killed without touching the body at all, by simply throwing germicidal rays into the interior of the patient. With a Tesla apparatus he had operated upon a cultivation of diphtheria microbes for twelve hours, but they grew as fast as ever, and he was sorry to say he had no result at all. But he did not regard this as the end of the subject, for he thought it quite possible that, with higher power than he had used, something more satisfactory might be obtained. He had found that rapid plates gave better results than slower plates, exposures being equal.

Mr. W. E. DEBENHAM suggested that, in order to obviate the necessity for "resting" the tube during exposure, duplicate tubes should be utilised, being alternately brought into position and illuminated for a short time, the exposure thus being continuous.

Mr. SWINTON thought this a very good idea.

The EARL OF CRAWFORD asked whether any experiments had been made in which the sensitive film was spread upon a support which would not fluoresce?

The ASSISTANT SECRETARY said he had tried ferrotype plates coated with a rapid collodion emulsion, but had been unable to obtain any results whatever.

Mr. SWINTON remarked that it had been suggested that, if the plate were heated, so as to increase the fluorescence, the exposure might be reduced very greatly, but he and Mr. Stanton had been unable to produce the slightest difference by this means.

A vote of thanks having been accorded to Mr. Swinton, the proceedings terminated, but a large number of members and visitors remained to witness a

further demonstration of the process and to examine the apparatus employed. The meeting was a "record" one, the Society's room being inconveniently crowded during the whole of the evening.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

FEBRUARY 6,—Mr. H. C. Rapson in the chair.

EXHIBITION OF PICTURES.

The HON. SECRETARY drew attention to the exhibition of pictures kindly provided and arranged in the room by Mr. W. D. Welford, with the aid of Mr. Fortune.

Mr. W. D. WELFORD, in introducing the exhibition of pictures by American and foreign workers, said he had a bureau scheme in operation, in which he acted as an agent for a number of foreign exhibitors, sending their pictures to the various exhibitions, and generally looking after their interests, and was thereby enabled to provide the present display. He thought it was to some extent a novelty and a welcome change in the ordinary routine of society meetings. In an hotel, where it is often impossible to obtain previous possession of the meeting room, except for a short time, he found that some arrangement for the rapid hanging of the pictures was a necessity, and, in conjunction with Mr. C. E. Fortune, he had constructed a series of screens, made of light wood, so as to be portable. These are joined in pairs after the system of clothes-horses, and made rigid by a cross piece at the back, and provide a convenient hanging space about sixty-four feet long. Upon these frames were hung the photographs, numbering in all about 120, of which one-third were framed and the rest simply mounted. Some idea of the rapidity of arrangement may be gleaned from the fact that at 7.15 the room's condition was normal, and at 8 o'clock all four sides were hung with photographs, titled, &c. Mr. Welford thought the members would agree that an examination of the pictures would give evidence that some attempts had been made beyond simply reproducing a transcript of what was before them, and showed careful study of the subject. The exhibitors included many well-known names from America, and Canada, Spain, Germany, and Austria were also represented.

The HON. SECRETARY proposed a hearty vote of thanks to both Mr. Welford and Mr. Fortune for the evening they had given the members, which was seconded by Mr. J. E. HODD and carried *nem. con.*, and these gentlemen briefly replied.

HALOGENS.

A question from the box was read: "Why are halogens so called?"

Mr. W. E. DEBENHAM, speaking from memory, said the word was derived from the Greek, *hals*, meaning sea salt, and was also applied to bromine, iodine, &c., on account of their tendency to produce salts similar in composition to sea salts.

CONTRAST IN DEVELOPMENT.

The HON. SECRETARY, referring to the competition arranged between Mr. Welford and Mr. A. E. Smith, said the plates he exposed were two of Marion's portrait plates. The subject selected he thought was pretty equal on both halves of the plate, and constituted a very fair test subject. The results were passed round.

Mr. WELFORD detailed his mode of development. One was done with ordinary washing soda and dry pyro, and the second with carbonate of soda and dry pyro, in both cases there being an entire absence of any restrainer beyond that peculiar to the soda. His object in the competition had been simply to prove that the yellow negative gave a more brilliant print than the blue-toned negative.

Mr. DEBENHAM would have liked to have seen clearer shadows in both pairs, and suggested that the plates had been fogged.

The HON. SECRETARY stated that, as each competitor had received the right-hand half of one and the left of the other, and there was no fog on the rebate of Mr. Welford's plates, that was out of the question as far as he was concerned, although Mr. Smith might have fogged his subsequently. He thought there was no silver in the yellow stain, and that it was due to the developer, and not to the silver in the plate.

Mr. A. E. SMITH had used the Ilford Universal developer, with the addition in the case of one of two grains of bromide to the ounce extra, the result appearing to be very much over-exposed. In the second case four grains of bromide obtained one somewhat clearer. He did not think the plates had been fogged by his lamp. Development was complete in about four minutes.

Mr. DEBENHAM, in answer to the Secretary, said his grounds for saying the plates had been over-exposed was that certain sash bars were entirely lost in one case. The fact that, with four grains additional bromide in one of Mr. Smith's trials, the plate developed in four minutes pointed to over-exposure, in his opinion.

Mr. WELFORD thought the question of over-exposure entirely answered by his negatives, with which no restrainer was used and no precaution taken. The stain on the edges was in due proportion to that on the rest of the plate.

Mr. BAYSTON inquired as to the temperature of the solutions, and it was ascertained that Mr. Smith's were rather warm, while Mr. Welford's were quite cold, which was conducive to contrast.

Mr. R. A. HODD had always found Marion's portrait plate fog very much with hydroquinone, but not so with pyro.

The CHAIRMAN thought that certain wire gauze would have been lost in the event of over-exposure.

Mr. TEAPE considered that, on account of the fog in the plates developed with hydroquinone, nothing like a comparison could be attempted between the two developers, and suggested that the trials be repeated.

Mr. WELFORD, although not wishing any one to think he was desirous of resting on his laurels, could not undertake to continue the contest, and the matter dropped.

Brixton and Clapham Camera Club.—February 4, Mr. W. Fraser (Vice-President) in the chair.—This was a Lantern Evening, a series of slides,

THE ANTIQUITIES AND HISTORICAL BUILDINGS OF ESSEX,

more particularly of Colchester and its neighbourhood, being shown by Mr. George Biddell, who gave a very entertaining and instructive description of the subjects illustrated, and, in conclusion, urged upon his audience the desirability of devoting their attention to one special branch of photography, thus obtaining, in the course of a year or two, a collection of photographs far more valuable than a similar number without any definite connexion between them. A lantern-slide competition, open to members, will be held Tuesday, March 3. The first prize is a bronze medal, offered by the President, other prizes for second and third position being given by Mr. W. Fraser. Six slides (preferably of a connected series) are to be sent in (before February 25) by each competitor, and must be accompanied by a brief descriptive account. The prizes will be awarded by three Judges chosen by the members.

Camera Club.—At the usual Thursday night's meeting last week, Colonel Stewart showed his perfected

PANORAMIC CAMERA,

together with many excellent specimen photographs taken by its aid. In general construction his camera remains as before, but it has been much improved by the substitution of toothed gearing for the belt previously employed. It will be remembered that this camera, by the action of clockwork, travels round on a horizontal table, so that from any high point a view of the entire horizon can be obtained. The negative is taken on rollable film, which passes over two cylinders at the focal plane, a slit about half an inch in width allowing the rays from the lens to find access to the sensitive surface, which travels one way, while the camera moves in the opposite direction. There is a spirit level at the top of the camera, by which it is made truly horizontal; the operator then aims at the extreme left-hand point of the view to be included, presses a pneumatic bulb, which causes the slit in front to open, and the camera to move slowly and smoothly in a central pivot until the required picture is complete. By making the slit V-shaped, more exposure can be given to the foreground than to the sky, and the time of exposure can be regulated by a choice of stop, the speed of the clockwork being constant, and governed by a fly. It will be observed that, owing to the use of the slit, the marginal rays are cut off; therefore it is possible with this camera to use a single lens without fear of distortion. Colonel Stewart intends shortly to try the instrument for portrait groups, and hopes to get fine results. The camera, in its present form, is remarkably compact, and seems to offer no difficulty whatever in working. Colonel Stewart's demonstration was followed by a paper by Mr. EVANS, the subject being

LINCOLN CATHEDRAL.

This was by no means an ordinary lantern show, or we could not afford space to notice it, ordinary lantern shows being somewhat—well—exactly so; but Mr. Evans's paper was a well-considered and well-written account of a cathedral, which, according to Lord Grimthorpe, is the grandest we have, so far as its exterior is concerned. But his paper was not interesting alone on this account, for it showed how the camera, in capable hands, is able to make the most perfect records of architectural work, both in mass and in detail. At one moment we were shown a view of the grand central tower, with its unique ornamentation, and in the next some gargoyle or finial wrought by the loving hand of a mason who had something more than mere wages in his mind when he took chisel and mallet in hand. Mr. Evans is an expert photographer as well as an architectural student, and he is thus able to take each picture with a purpose, sometimes to show how the work of different centuries is dovetailed together, and sometimes to point out how the restorer's heavy hand has blotted out beauties which he could not appreciate. Beginning with the familiar view from the castle, which shows the broad mass of the Cathedral, towering over and dominating the city, its size being apparently increased by the low roofs in the foreground, Mr. Evans took each part of the beautiful structure in detail; the west front, more curious than architecturally satisfactory, with its Norman recesses, like huge sentry-boxes, and its quaint panels, borrowed from some Saxon church of earlier date; then each bit in detail, until one began to wonder what a mass of scaffolding must have been necessary to get the camera into position. The west front done with, we are shown the beauties of the other sides of the sacred fane, and then a lovely little picture of the stairway which leads to the interior. Here we see how the carvings have been hacked about by Cromwell's soldiers, who turned the place into a barrack and stable, and watered their horses at the font, finely carved out of black basalt. But much rich ornament remains, and Mr. Evans has paid such loving attention to it that he has enough pictures to illustrate a thick volume on the subject of Lincoln Cathedral. Would that all lantern shows were so well illustrated! In the course of a discussion which followed the reading of the paper, Mr. GAMBLE gave an interesting account of the way in which the inhabitants of the fen villages saved their valued churches from spoliation at the hands of Cromwell's lambs. When they heard that the soldiers were coming their way, they made preparation to welcome them with open arms, taking care to have ready plenty of alcoholic refreshment. The result was that the men became so helplessly drunk that they overslept themselves, and had no time the next morning to do more than normal damage to the village church. Lincoln neglected these tactics, and suffered perhaps more than it would have done if the soldiers had not, by force of circumstances, been debarred for some days from the pleasures of sacrilege. The evening's entertainment concluded by the exhibition by Mr. Bros of some interesting pictures which he had lately taken during a trip in Spain. These pictures were of the walls of Tarragona, which showed very curiously prehistoric work at their base, Roman work above that, and at the top of all far more modern masonry. These walls are more than twenty feet thick, and have a most extraordinary as well as picturesque effect. Nearly all the buildings in Tarragona show Roman work, and Mr. Bros seems to have found a new and useful field for photography in their reproduction.

Hackney Photographic Society.—February 4, Mr. E. Puttock presiding.—Mr. Guest showed an isochromatic film negative which had been fogged by exposure to the dark-room light—two thicknesses of ruby glass. The film had been developed in a transparent celluloid well dish, and, on holding the dish and film up to the light to judge density, the light had fogged the film through the transparent celluloid. Mrs. SNOWDEN WARD then gave a lantern lecture, illustrated by American exchange slides, and also by some made from negatives taken by the lecturer in and around Shrewsbury during the Convention week. Mr. SNOWDEN WARD showed a set of six slides, illustrative of work done by the new X rays, and gave at the same time an account of the work being done in the investigation of these newly discovered rays.

North Middlesex Photographic Society.—February 10.—Mr. T. E. FRESHWATER gave a lecture on

BEE CULTURE,

illustrated by the lantern. After describing very fully the insect itself, and its various parts, and the uses of each, such as the tongue and its sheath, the tracheal tubes, constituting the breathing apparatus, &c., he showed slides of hives, both old-fashioned and improved modern ones, with movable trays, which could be shifted when filled with honey. Among the slides were some showing the bees in the act of swarming and being transferred to their new hive. A parasite and various bacilli which prey on the bees were also shown. In view of the great interest shown lately in photographs taken by the X rays of Professor Röntgen, he wound up his lecture by exhibiting some slides from negatives taken by Mr. Swinton of a hand and a live frog, showing the bones through the flesh; also a razor, in which the blade showed through the handle; and coins inside a leather purse, &c. A hearty vote of thanks to the lecturer concluded the proceedings.

Putney Photographic Society.—February 4.—Dr. Cuthbert Wyman in the chair, when a return visit was made from the Kingston-on-Thames Society by Mr. Albert Hill, the subjects being

PHOTO PLASTICS, and TONING, INTENSIFYING, AND REDUCING WITH URANIUM.

Mr. Hill commenced by giving a brief description of photo plastics, exhibiting some interesting examples of photographs in relief, and a series of casts showing the correction of false modelling from the cabinet print to the copper-deposited portrait. Their uses for ornamental relief work and die-sinking were briefly touched on. The lecturer proceeded to give a demonstration on the uses of

URANIUM FOR TONING, INTENSIFYING, AND REDUCING.

Negatives and positives were treated, and the method of building up and reducing by ammonia and glycerine explained. His method of treating negatives of extreme contrasts was shown, which proved to be most effectual as well as simple in its working; finished negatives with prints taken at different stages were also exhibited. Bromide prints were then successfully toned.

Richmond Camera Club.—January 27.—Mr. CEMBRANO (the President) gave a useful and interesting address, entitled

MY CAMERA, HAND AND STAND, AND HOW I USE IT.

Though professedly elementary, it contained a number of hints, of value to more experienced workers as well as to beginners, on the subject of cameras and all their accessories.

FEBRUARY 3 was an Open Lantern Night. — Mr. Cembrano presided, and a very interesting series of slides, by Messrs. F. A. Bridge and A. Bridgman, entitled, *Our Tour in Norway*, was shown. The towns, villages, inhabitants, and natural scenery of Western Norway were admirably illustrated by some 180 pictures, which were well described by Mr. Bridge, and highly appreciated by his audience.

South London Photographic Society.—February 3, the President (Mr. F. W. Edwards) in the chair.—Mr. W. H. DAWSON, Vice-President of the Woolwich Photographic Society (under the scheme arranged between the Secretaries of the metropolitan photographic societies for the exchange of papers), gave an address on

THE CHEMISTRY OF EVERY-DAY PHOTOGRAPHY.

He dealt, first, with the support for the photographic film, and said that it should be transparent, not liable to change on keeping, and not acted upon by the chemicals used in development. Glass fulfilled those requirements in the highest sense. Celluloid was often used, and was highly electrical in its nature. It would be interesting to submit a plate and a film to the new rays, to ascertain whether the plate was more rapid than the film. Gelatine was used chiefly for holding the haloid salts. The various properties of gelatine were explained, and the methods by which those properties were taken advantage of in the manufacture of dry plates. The halogen salts of silver were then dealt with, and the changes which took place during exposure and development were explained by means of diagrams and symbols on the blackboard. Captain Abney's experiment of placing an exposed plate in bromide to destroy the effects of light was referred to. The chemistry of development was fully explained, together with the uses of the various chemicals used. In fixing after development, the lecturer said he used hypo as strong as the plate would stand, to prevent the formation of an insoluble salt, which could not be removed from the film. Reduction and intensification received their share of attention. Mr. Dawson said he seldom used mercury and ammonia for intensification, as he preferred Monckhoven's silver and cyanide method. Orthochromatic plates are either prepared by mixing the dye with the emulsion or by dissolving the dye in water with a little ammonia, and bathing the plate in the solution and drying it before use in a dark room. The chemistry of the various printing processes—platinotype, bromide, albumen, gelatino-chloride, &c.—brought the address to a conclusion, and was followed by a discussion on various points raised.

Bath Photographic Society.—January 29, Mr. Augustus F. Perren in the chair. Messrs. C. J. Taylor, A. Taylor, J. S. Turner, and E. Wright were elected members of the Society. Messrs. E. J. Appleby and J. A. Howe were reappointed Auditors of the accounts. A discussion on the new discovery in photography was opened by Mr. AUSTIN J. KING, who, having recapitulated all known information on the subject, suggested that the Society should obtain the services of a capable lecturer to demonstrate in Bath at an early date. Mr. W. PUMPHREY considered it most desirable the Society should take immediate steps to elucidate by demonstration all known facts. The Secretary was instructed to make the necessary arrangements without delay.

Birmingham Photographic Society.—February 4.—the PRESIDENT (Sir J. Benjamin Stone, M.P.) exhibited about 100

PHOTOGRAPHS OF THE TRANSVAAL AND SOUTH AFRICA,

taken by himself during a two-months' tour with his daughter. Sir Benjamin gave a short discourse, during which he said: "Starting from the Cape, we travelled in a wagon, visiting all the places of interest, and obtaining an amount of knowledge of South African life which it would have been impossible to so accurately acquire in any other or more agreeable way." Sir Benjamin never carried arms, but was protected by his four Zulu servants, and the tour was accomplished without accident or alarming incident. During the tour he exposed about 600 whole-plates, most of them being films. He had an interview with President Krüger, who, it is said, could speak the English language, and yet, during the interview, he would only converse with him (Sir Benjamin) by the aid of an interpreter.

Moseley and District Photographic Society.—February 7, Dr. Hall Edwards (President) in the chair.—Attendance, thirty-seven. The minutes of the inaugural meeting being read and signed, a short discussion took place in connexion with the new radiation photography. Dr. Hall Edwards passed round for inspection the first photograph he had produced by means of the X rays. The print, an exceedingly good specimen, showed a half-crown, a sixpenny piece, a picture ring, two keys, and a microscopic cover glass. These were all taken through a sheet of aluminium one-thirty-second of an inch in thickness, and four layers of black paper. The interesting point in the photograph was the clearness with which the microscopic cover glass was depicted, although its thickness was not more than one-hundred-and-twentieth of an inch. This, we believe, was the first photograph taken in the Midlands by means of the new X rays. The PRESIDENT then called on Mr. HUBERT COOP, artist, to deliver his lecture on art, entitled

A FEW REMARKS IN CONNEXION WITH PICTURE-MAKING.

He presumed that the object of the artist, or artist-photographer, was not only to present the picture of a place or locality, but to present it in an artistic way, so as to be interesting, pleasing, and valuable, not only to those that are acquainted with it, but also to those that are not, and to depict the scene with the most appropriate sentiment and effect. He thought the name of the locality the least important point about a picture. Photographers, he felt, often sacrificed the composition of a subject to the size of the plate; a small portion from, perhaps, one of the sides, the top or bottom, would make a good composition, whereas, otherwise, the pictorial effect would be lost. He admitted that photographic artists were considerably handicapped in not being able to take liberties with nature. Good composition is most essential to a good pictnre. The principal masses should be nicely grouped, and not scattered promiscuously about. In illustration of his remarks Mr. Hubert Coop sketched in charcoal an outline as a study of composition, gradually filling in as necessary to illustrate his remarks. He started by drawing in the horizon, high up in the picture. He preferred a high horizon, and gave as a reason that having a more expansive foreground gave more scope for the introduction of an incident, drawing in with lightning rapidity a splendidly drawn boat on the right-hand side. That being his principal object and chief point of interest, he ststed that all subordinate objects should lead the eye up to it. He laid special stress in warning them not to have two points of interest of equal or nearly equal strength, but only to have one great interest, all others being secondary. Photographers made a very great mistake in so carefully avoiding to photograph facing the light, so much of the untrue detail which is so often seen in a photograph is thus lost. He advised the artist photographer, when looking for subjects, to try and imagine them under different effects of light, and only when the best lighting appeared to take the picture. In touching elaborately on relative tone values, he stated that most photographic pictures were out of tone, mostly too dark. He advised his audience always to aim at an effect; if they did not, they would be liable to get a nature-at-dinner-time sort of look about their picture. Any incident introduced should retain an accidental look, and not have the appearance of having been placed there, and should be strictly in keeping with all its surroundings. The introduction of a figure is not sufficient, there must be some apparent reason for it. He illustrated how the sky formed a most important feature in improving or spoiling the composition. If the principal lines of the composition run from right down to left, the sky clouds should generally run from left down to right. In conclusion, it would be well to bear in mind that the artist appeals to your imagination, and he *never attempts* to deceive your eye, like a conjuror. The artist was kind enough to leave the sketch to grace the walls of the meeting room, by special request of Dr. Hall Edwards, the President.

Oxford Camera Club.—The Annual General Meeting of the Club was held on February 3. The report of the Secretaries showed a steady increase in the membership, the number having risen from fifty-eight to seventy-five, the latter figure including thirteen ladies. Eighteen meetings have been held during the past year. Since July the Club has had the privilege of meeting in the University Museum, an advantage which has been much appreciated. The Treasurer's report showed a balance of nearly 9*l.*, including a profit of 16*s.* from the Exhibition held in November. A few slight alterations in the rules were then passed, and the officers elected for the ensuing year. A set of slides, by the Manchester Society, obtained through the affiliated societies, was then shown on the screen. During this part of the programme the Secretaries showed the working of one of Mr. G. Davenport's curtain-effect carriers. This

worked very well and smoothly, and was on the table for inspection at the end of the meeting. Where a curtain effect is desired, nothing better could be wished.

Plymouth Photographic Society.—

FLASHLIGHT PICTURES.

On Friday, February 7, the PRESIDENT of the Society (Mr. E. H. Micklewood) demonstrated to some forty members and friends, using for the purpose a flashlight lamp made after the pattern of those used by Mr. Burran, of Cambourne, who has produced such excellent photographs of Cornish mines. Mr. Micklewood made two flashes, using pure magnesium powder, and, as a result, some thirty plates were exposed by the members present. One negative was developed by the demonstrator, and proved of very excellent quality. Mr. Micklewood made the subject very interesting, showing prints of flashlight pictures of the principal scenes in the local pantomime of *Dick Whittington*, at the Theatre Royal. Four new members were elected, the member roll now approaching sixty.

Edinburgh Photographic Society.—A lecture was delivered on January 30 by Mr. H. Bellyse Baildon, M.A.Cantab., F.R.S.E., Sir James Russell in the chair.—The subject was

THE PAPUAN AT HOME,

to illustrate which Mr. Baildon showed a large number of slides from photographs which he had taken while on a visit to New Guinea. The lecture was much appreciated by a large audience, and Mr. Baildon was accorded a very hearty vote of thanks for his kindness in providing such an interesting evening. Thanks to the energy of the Secretary, Mr. J. S. McCulloch, W.S., a number of slides from negatives by Dr. Dawson Turner, Edinburgh, and Mr. A. Campbell Swinton, London, illustrative of the new electric photography, were shown on the screen at the close of the lecture just referred to. A photograph of the skeleton of a lady's foot, showing malformation of one of the bones of the little toe through tight boots, and another of a frog taken through a sheet of aluminium especially attracted attention. Most of the slides were made by Messrs. Walls & Fraser, Lothian-street; and a new lantern, specially built for the Society by Mr. A. H. Baird, F.R.P.S., Lothian-street, was used for the first time at this meeting. It gave much satisfaction. The

ANNUAL EXHIBITION OF THE SOCIETY

was opened on Saturday, February 1, by Mr. F. W. Carter, C.A. The Exhibition is to remain open for a month, and an entertainment will be provided every Saturday evening. Mr. Chas. A. Stitt and Mr. James Patrick have each consented to give a lecture, the former having chosen as a title "Looking Backward," and the latter "The Early Home and Haunts of Robert Louis Stevenson." Messrs. Stitt and Patrick have both been heard before, and their names have only to be mentioned to ensure a crowded house. The other Saturday nights will be devoted to music. The Exhibition this year is distinctly the best that the Society has yet held, the work being of a high standard of excellence. A steady progressive movement has been noticed for many years past, but this year a greater stride than usual seems to have been taken, owing, no doubt, partly to the large increase in the number of members, and partly to the increasing attention which workers are paying to the art side of photography. A new feature this year is the introduction of an open class—a good move, as it gives an opportunity to members of comparing their own pictures with those of the best outside workers, and thus the standard of work is sure to be raised. Two very strong sections in the show are the class for amateurs only and the Lady Members' Class, the latter containing some very beautiful work indeed. Class III. (for figure studies) also contains some very good pictures. In fact, taking the Exhibition all round, it is quite a success. Sir Francis Powell, P.R.W.S., Mr. W. Crooke, and Mr. W. M. Warneuke acted as Judges, and made the following awards:—Section I. (open to members and non-members, subject optional): No. 19, silver medal, J. B. Johnstone; No. 11, silver medal, John H. Gear, F.R.P.S.; No. 13, bronze medal, E. R. Ashton. Section II. (open to members only): Class I. Best set of six lantern slides—silver medal, James Patrick; bronze medal, Charles Alfred Stitt. Class II. Best picture, half-plate size and under—No. 114, silver medal, James Hay; No. 124, bronze medal, Miss Christian H. Curle; No. 116, bronze medal, Alexander Allan. Class III. Best figure or *genre* composition—No. 177, silver medal, John Warrack, jun.; No. 182, bronze medal, John Warrack, jun. Class IV. Best picture above half-plate size, other than figure or *genre* composition—no awards. Class V. Hand-camera work, five or more pictures—No. 189, silver medal, Charles A. Stitt; No. 195, bronze medal, Alex. McNab; No. 197, bronze medal, James Hay. Class VI. Best picture, being the work of a lady member—No. 165, silver medal, Miss Daisy Duncan; No. 134, bronze medal, Miss Christian H. Curle. Class VII. Best set of three pictures taken at the 1895 Saturday rambles—No. 169, bronze medal, Alexander Allan. Class VIII. Best enlargement—No. 55, silver medal, J. B. Johnstone: No. 54, bronze medal, C. W. Sinclair. Section III. (amateur members only; best direct picture): No. 68, silver medal, Douglas Croall; No. 74, bronze medal, J. R. Roddick.

FEBRUARY 5, Mr. James Patrick (Vice-President) in the chair.—A lecture on

ANIMAL PHOTOGRAPHY

was delivered by Mr. CHARLES REID, of Wishaw, who is well known as an authority on this subject. Interspersed with anecdotes, of which Mr. Reid possesses a rare fund, and illustrated by a series of slides which, for artistic and technical excellence, are second to none, the lecture could not fail to be highly interesting, even to those who knew very little about photography. Great admiration was expressed for the manner in which the pictures, many of which must have been taken under the most trying circumstances, were composed and lighted, a considerable number of the subjects having been taken right against the light. At intervals during the lecture music was provided, and at the close hearty votes of thanks were accorded Mr. Reid and all who had contributed towards the evening's enjoyment.

FORTHCOMING EXHIBITIONS.

1896.		
February 27-29	Woolwich Photographic Society.	
March 2-6	*South London Photographic Society.	Hon. Secretary, Charles H. Oakden, 30, Henslowe-road, East Dulwich, S.E.
,, 3-6	*Cheltenham Amateur Photographic Society.	Philip Thomas, College Pharmacy, Cheltenham.

* Signifies that there are Open Classes.

Correspondence.

PHOTO-CHROMOSCOPES.

To the EDITORS.

GENTLEMEN,—Mr. Edwards has kindly shown me the photo-chromoscope which is figured on page 85, and also a three-step photo-chromoscope which, he informs me, was his first model. I cannot doubt his statement that he conceived the idea independently, notwithstanding the fact that my United States patent, disclosing everything, was published more than two months before he even applied for provisional protection.

Like Mr. Edwards, I had the idea in mind (as a three-step instrument) long before (in my case some years before) I applied for a patent. I waited to invent the folding chromogram, the two-step construction, and other improvements, and then my *complete* specification was filed about a year and a half before Mr. Edwards! I even claimed the use of the apparatus as a camera, although I have something better for that purpose; and I use coloured glass reflectors instead of thinly silvered mirrors, because they are more perfect for a viewing instrument, cheaper and less easily damaged. The silvered mirrors have to be varnished to prevent tarnishing, and cannot be cleaned by rubbing, like the coloured glasses—a serious defect in an instrument which has to be kept in order by ordinary purchasers.

It is evident that, inasmuch as they have been constructed in accordance with my patent specifications, and for the purposes specified therein, and are infringements of my patent claims, neither the instrument described by Mons. Vidal nor that constructed by Mr. Edwards can be properly described as "other photo-chromoscopes . . . . that produce equally remarkable results."—I am, yours, &c., F. E. IVES.

119, *Shaftesbury-avenue, W.C., February 7*, 1896.

COLOUR RENDERING ON ORDINARY PLATES.

To the EDITORS.

GENTLEMEN,—The insertion of the enclosed copy of letter, sent to the Hon. Secretary of the Croydon Camera Club will oblige.—I am, yours, &c., E. J. WALL.

[COPY.]

DEAR SIR,—According to the reports which have appeared in the photographic journals, Mr. G. R. White said, in a lecture before your Club:—

1. "That ordinary plates will, providing a full exposure be given, yield results in colour rendering not interior to those of isochromatic ones."

2. "That the improvement in colour rendering possible with an isochromatic plate is not exhibited unless a prodigiously dark screen be used and an exposure is given several *thousand times* longer than is needful with an ordinary plate without a screen."

These, it is stated, are conclusions deduced from numerous experiments, and as they are at total variance with the results obtained by Vogel since 1873, by Eder, Abney, Schumann, Bothamley, &c., and my own work begun in 1889, I challenge Mr. White to meet me before some independent and competent body such as the Photographic Club or the London and Provincial Photographic Association, to prove his statements or allow me to disprove them.

I shall be glad if you will communicate the contents of this letter to Mr. White and your members at your next meeting, and let me know Mr. White's decision.

In conclusion, I beg to inform you that I am sending a copy of this letter to all the photographic journals.—Yours truly, E. J. WALL.

PHOTOGRAPHIC COPYRIGHT.

To the EDITORS.

GENTLEMEN,—A writer in a monthly contemporary, under the heading of "Cast Iron Laws," makes some reflections on Rule 23 of the Photographic Copyright Union—a rule which he admits is excellent in principle, and with which he states himself to be in full agreement. But evidently, in the writer's mind, there is a disinclination that the rule should

be strictly observed, he wants exceptions to be made. What is a rule or law but a positive assertion of a principle that must be absolutely followed—permissive rules or permissive laws are not worth the paper on which they are printed? That is common experience; and there is no escape from this. If a rule is a good rule, it must be followed implicitly; if a bad one, the only course is to cancel it.

For the benefit of your readers I give the rule in full.

Rule 23.—That no member shall allow a copyright picture belonging to him to be reproduced (whether registered or not) for a less fee than 10*s.* 6*d.* on each occasion, and for each different publication or form in which it is used, but he shall be at liberty to charge a larger fee according to his own ideas as to its value.

Even in the best rules that have ever been made, there must be times when they will cause an apparent loss. It is impossible to make a rule that will cover every possible circumstance. It is quite sufficient if its strict observance secures the greatest amount of benefit. This, I believe, to be the case with our Rule 23. It was not adopted without repeated discussions by those most interested in obtaining a successful result.

As regards the minimum fee for the right to reproduce landscape photographs, this was arrived at after discussion by thirty of the leading view publishers and view photographers in the Kingdom; and, as yet, I have not heard one of them express an opinion that it has not acted quite satisfactorily for their interests.

The journalistic photographers—or proprietors of photographic newspapers—should be the last to beat down the price for reproduction of copyrights. The photographer who sells this right for book illustrations is certainly not the one who will agree with the *Photographic News* that he should be contented to receive a less fee than that advocated by the Photographic Copyright Union. It has been proved over and over again that the publishers can well afford to pay this small fee.

We trust the writer of "Cast Iron Laws" will, on further consideration, think fit to take the same view of this matter as the Photographic Copyright Union; and certainly, journals especially devoted to photography, should stand shoulder to shoulder with those who are labouring to protect the copyright interests of the profession generally.—I am, yours, &c., HENRY GOWER, *Secretary (for the Committee)*,

Botolph House, Eastcheap, London, E.C., February 10, 1896.

THE RECENT LIMELIGHT COMPETITION.

To the EDITORS.

GENTLEMEN,—If Mr. Gwyer's letter in your last issue means anything at all, it means that the Chairman, the members, and reporting Secretary of the Photographic Club, present at Anderton's Hotel on January 22, are an aggregation of dishonourable men, who conspired to rob him of his just due; otherwise, how is it that, in view of the fact that the Chairman declared, with the concurrence of all the gentlemen present, and in Mr. Gwyer's hearing, that his jet and mine were considered to be of equal light-giving power, he should write to you feigning surprise that the result was so reported in your JOURNAL?

The statements contained in Mr. Gwyer's letter are directly contrary to fact; for instance, the first result was not declared in his favour but in mine, I being 100 against his ninety-five, or five points to the good; the second result gave Mr. Gwyer 100 and me ninety-nine, or one point to him, whereupon I stated that I was willing to consider it a tie. A third trial subsequently took place and the result was declared a tie.

I do not propose to correct all the inaccuracies of which Mr. Gwyer's letter is compounded, but I make him a practical offer, which, if accepted, will settle conclusively the question at issue.

I suggest that we submit our respective jets, with a series of nipples of from, say, one-twelfth-inch to one-twenty-fourth inch bore, to Mr. Hearson (with whom I am unacquainted), and one or two more independent experts to be nominated, Mr. Editor, by you, with instructions to test one against the other in any and every way they may think fit; that Mr. Gwyer and I be not present nor have anything whatever to do with the testing; that the report of the referees be published in your JOURNAL; that such report be considered conclusive as to the merits of the respective jets, and that the owner of the losing jet pay the costs of the reference.

I am also willing, if agreeable to Mr. Gwyer, to add a further condition, viz., that the loser give twenty guineas to a charity to be named by the winner.

If Mr. Gwyer is so cock-sure of the superiority of his jet, here is an excellent opportunity for him to prove it, besides benefiting some deserving institution and getting a splendid advertisement for himself as a jet-maker into the bargain.

I am only an unsophisticated amateur myself, with no axe to grind, so, if Mr. Gwyer succeeds, I shall be prepared to congratulate him as heartily as any one; but I cannot congratulate him upon his sense of fairness as disclosed in the letter to which I am now replying.

In that letter he refers to the size of the chamber of my jet, but he is discreetly silent as to the bore of the nipple *he* used being more than one-third larger than mine, viz., ·085 as against ·072, which is a most important consideration; nor does he inform you that, owing to the small size of the lanterns available at the competition, my jet had to be taken off base plate, tipped forward, and held in position in the fingers during the testing, and was never properly centered, a fact perfectly well known to Mr. Gwyer and every one else present. Any one who knows anything about lantern work will realise the difficulty I had to contend with in competing at all under such conditions, and yet, notwithstanding, I managed to tie with my opponent. Although Mr. Gwyer says his jet was burning the whole evening, which was not the fact, he does not mention that he started a fresh lime, supplied from my own tin, immediately before every trial.

In conclusion, let me say that my offer means business, which is much more to the point than paper warfare. Let Mr. Gwyer either accept it or hold his peace. At any rate, if he must rush again into print, I trust he will do so in the spirit he displayed at the competition, and not as exhibited in his last letter to you.—I am, yours, &c.,

Crouch End, February 8, 1896. W. SCARBOROUGH.

THE LEEDS CONVENTION.

To the EDITORS.

GENTLEMEN,—Will you kindly allow me to remind your readers that the Photographic Convention of the United Kingdom will, this year, hold their annual gathering at Leeds, in the week commencing Monday, July 13, and under the Presidency of H. P. Robinson, Esq.

The Leeds Reception Committee numbers fifty-six of the leading residents of the district, the executive branch of this Committee consists of Messrs. J. H. Walker (Chairman), Herbert Denison (Hon. Treasurer), B. A. Burrell, Washington Teesdale, W. J. Warren, H. F. Wigglesworth, and Dr. J. T. Thresh, Mr. Godfrey Bingley, of Thorniehurst, Headingley, Leeds, holding the position of Local Hon. Secretary.

The above executive Committee have held several meetings during the last few months, and their arrangements are approaching completion.

Important papers will be read and discussed, and there will be various demonstrations of practical utility to all photographers.

The rooms of the Leeds Philosophical Society have been secured for the Convention week; their central position and conveniences will be much appreciated by Conventioners.

The Mayor of Leeds (the Right Hon. W. L. Jackson, M.P.) has kindly offered to "receive" the members of the Convention on Monday evening, July 13.

Attractive excursions have been arranged for, amongst other places to Bolton Abbey and Bolton Woods, Kirkstall Abbey, York with its famous Cathedral, Richmond (Yorks), Ripon, Studley, and Fountains Abbey, Knaresborough; and Plumpton Rocks (Harrogate), the well-known watering place is about two miles distant from Knaresborough.

From accounts from various sources a very large attendance is anticipated, probably exceeding that of any former Convention, which will be, doubtless, exceedingly gratifying to that ever-popular veteran, Mr. H. P. Robinson, who will occupy the presidential chair at Leeds.

The Council of the Convention wish to impress upon all members who attended the memorable Shrewsbury Convention of last year the importance of bringing or sending to Leeds for exhibition during the week of Convention lantern slides from the negatives taken while in Shropshire.

Gentlemen wishing to make trade exhibits of processes or apparatus (for which there are great facilities) during the Convention week, or who would desire to advertise in the official programme of the Convention (the only one to be issued), will kindly communicate either to Mr. Godfrey Bingley, the Local Hon. Secretary (address as above), or to yours, &c., R. POULTER DRAGE, *Hon. Secretary P.C.U.K.*,

95, *Blenheim-crescent, London, W.*

P.S.—The annual subscription is now due.

SAPIENT SUGGESTIONS.

To the EDITORS.

GENTLEMEN,—"An Old Member" has triumphed over me, for I have unreservedly to confess that I am wrong and he is right about Charles II. I thank him for the moderation he has displayed in his victory.

The "dreadful shame" I feel is, however, not unmixed with pleasure, for, at least, I have enabled him to experience an unusual and delightful sensation in being right for once; and—who knows?—perhaps having once attained that brilliant position, he will try to maintain it, and will become quite a good boy, be rewarded with that honorary fellowship, and live happily ever after.—I am, yours, &c., ANOTHER OLD MEMBER.

[This correspondence here terminates.—EDS.]

THE PHARMACEUTICAL SOCIETY.

To the EDITORS.

GENTLEMEN,—I am sorry I cannot spare the time just now for a thorough analysis of "J. A. C. O.'s" letter. Would it be too much, meanwhile, to ask for further particulars and details of the immense suffering, the crippled and struggling industries, and general stagnation,

&c., caused by this poison monopoly——bearing in mind "J. A. C. O.'s" admission, relative to the facilities afforded by our own and foreign wholesale houses for the supply of these scheduled chemicals?

I suspect our friend to hold a brief on behalf of the the class of legally oppressed men anxious to become lawyers, medical practitioners, chemists, and the like, without going through the requisite preliminaries. Lots of people, no doubt, would support a return to the *status quo ante*, and abolish monopoly everywhere.

The sole object of my letter was to point out, what I think is incontestable, that from the earliest days the sale of photographic chemicals has been in the hands of chemists and druggists, and that they are, by examination, equal to the demands made upon them.—I am, yours, &c.,

D. D.

THE CATHODE RAYS.

To the EDITORS.

GENTLEMEN,—You have made an error saying Crookes had first discovered the cathodic light. It was the German philosopher, Hittorf, who first introduced it to the science, and Crookes imitated it.

It was an accidental discovery, as Columbus discovered America, and why that envy?—I am, yours, &c.,

MARIE WALDE.

51, *Gower-place, Euston-square, W.C.*

HALATION.*

IF one takes a photograph of an object in which the contrast between light and shade is very marked, the negative shows, if certain precautions have not been taken, a nebulous luminosity round the light, which makes the picture at this place indistinct. It has been believed, until now, that this phenomenon was caused by reflections from the back part of the glass plate; the author, however, is of a different opinion.

If the hypothesis mentioned above is correct, some parts of the picture showing halation should be double; but this is not the case.

Also, he believes that the strongly dispersive power of the emulsion layer would prevent the reflection of the transmitted light from the second surface. The light, after leaving the emulsion layer, is quite equal, and would, on getting to the back part of the plate, cause, at the most, a general fog; but that does not happen.

Founded on accurate research, the author gives it as his opinion that the phenomenon of halation is caused by interference. It seems to be produced by light reflections in the inner part of the camera, *i.e.*, from the blackened inner surface of the objective mounting. It may be avoided if the objective is protected against injurious light or if the inclination of the apparatus is altered a little.

R. ROUSSEAU.

THE PHOSPHORESCENCE OF GELATINE PLATES.†

THE phenomenon, observed by several experimentalists of gelatine plates, soaked in a pyrogallic acid developer, becoming luminous when placed in a dilute solution of citric acid, is caused, says the author, by a process of oxidation which gives rise to a luminosity identical with that produced during the slow oxidation of phosphorus, and renders it probable that all processes of rapid oxidation are accompanied by evolution of light, even when the oxidation takes place in aqueous solution, though a certain intensity of oxidation is required to give rise to it.

Other developers than pyrogallol, even when possessing a nearly similar constitution and properties, such as hydroquinone, do not give rise to luminosity.

The cause of the luminosity is explained by the author in the following way:—

1. The alkaline pyrogallol solution gives, on addition of acids, oxygen which oxydises the sodium sulphite in the developer to sodium sulphate, with evolution of light.

2. The pyrogallol solution, when mixed with caustic soda and sodium sulphite, absorbs oxygen from the air, and this oxydation is also accompanied by evolution of light.

The correctness of this explanation is rendered probable by the fact that easily reducible bodies, such as permanganate of potash, give out light on addition of alkaline pyrogallol solution.

When sodium sulphite combines with oxygen in the presence of pyrogallol, no luminosity is produced even if the pyrogallol has been previously slightly oxidised; but, when alkaline pyrogallol solution, which has been partly oxidised, is decomposed by the addition of acid, the author considers it probable that some of the oxidation products of pyrogallol are decomposed with evolution of oxygen, which combines with the sodium sulphite, forming sulphate, and thus giving rise to luminosity.

Answers to Correspondents.

*** *All matters intended for the text portion of this* JOURNAL, *including queries, must be addressed to* "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 2, *York-street, Covent Garden, London. Inattention to this ensures delay.*

*** *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

*** *Communications relating to Advertisements and general business affairs should be addressed to Messrs.* HENRY GREENWOOD & CO., 2, *York-street, Covent Garden, London.*

PHOTOGRAPHS REGISTERED:—

Mr. L. M. Williams, 1, Upper Camden-place, Bath.—*Three cabinet photographs of Rev. Canon James Fleming.*

William Harrison, per S. Thorn, 18, The Crescent, Bude, Cornwall.—*Two views of dining hall, and one view of drawing-room, at Tonnacombe House, Moorwinstow, Cornwall.*

M. STARITANOFF.—Please send address and particulars.

LENSES.—L. M. (Dublin). Our experience is that, under equality of conditions, there is little to choose between them.

RESIDUES.—W. SMITH writes: "Is it any good saving the pyro developer for the silver it contains?"—In reply: No; it contains none.

BLUE-BLACK TONE ON PLATINUM PRINTS.—PRINTER. See Mr. Dolland's paper in the JOURNAL for March 1, 1895, which describes a process for giving a blue-black tone to platinum prints.

SMALL GAS BUANEAS.—H. ABBOTT. Any gasfitter will obtain them to order, if he has them not in stock. They may be had in wholesale quantities from Messrs. Hulet & Co., Holborn, we believe.

SPOTTING COLOURS.—E. LAVENDER. Spotting colours, that will answer the purpose, are supplied by all the dealers. Mr. Rudowsky, 3, Guildhall-chambers, E.C., also supplies special spotting colour.

ADDRESS WANTED.—W. N. (Biarritz).—We presume you mean the plate-makers. The only address we know of is, Cours Gambetta et Rue Saint Victor, Monplaisir-Lyon.

NON-RETURN OF SPECIMENS.—J. BLENKINSOPP has suffered from those people who ask for specimens and do not return them, and asks, "What can I do?"—In reply: Write to the Superintendent of Police in the town, giving him a short account of your experience.

CARBON PRINTING.—T. MCCARTHY. A sensitising bath of three and a half per cent. will be a suitable one for general work. Five per cent. may be used for negatives with excessive contrasts with advantage, but it will be too strong for thin and feeble negatives, unless the time of the immersion of the tissue is very short.

COLOURED EFFECTS ON THE LANTERN.—A. SIMMONS. Coloured gelatine films can be used in the lantern, but they are not to be recommended, as with the heat they get dry and brittle. If they contain moisture, they are liable to buckle and lose their flatness. Coloured glasses are much to be preferred.

FADING.—S. O. R.—The print enclosed is not a sample of the way that albumen pictures fade in a few weeks, because the image has not faded at all. The change, where the picture is not shielded by the mount, is due to the fading of the rose tint of the paper; hence your strictures on the albumen process come to nothing.

MATT VARNISH.—GEORGE DANIELS writes: "I am told that a solution of saudarac in toluol makes a good matt varnish. Can you tell me what proportions are the best to employ?" In reply: Dissolve 100 grains of sandarac in two drachms of ether. Filter the solution through a tuft of cotton-wool, and then add six drachms of toluol.

RELIEFS.—T. WHARTON. It is quite possible to take a cast in fusible metal from a gelatine relief which will be perfectly sharp, but, of course, the gelatine must be quite dry. The metal cannot be employed for casting from a moist relief in its "swelled" state, as the heat would cause it to run. If a cast from a swelled gelatine relief is required, plaster of Paris is the thing to use.

LENSES.—T. W. R. The case of six lenses and one mount in a case, bearing the name of A. Darlot, is a set of lenses of different foci. By screwing the different glasses at either end of the tube, doublets of various foci are obtained. They have to be used with comparatively small stops, and with them a large angle of view may be obtained. They are, of course, somewhat slow in action.

BACKGROUND.—E. DESMOND. If the canvas has got so slack and fluted as stated, there is nothing to be done but to take it off the frame and restrain it, and that should be done before it is reflatted. If the frame were made with wedged corners, like the "strainers" of artists' canvases, they need only be driven a little tighter, which would do the necessary stretching. Background frames should always be made on that principle.

EMAMELLING PRINTS.—OXON complains of small air bubbles getting imprisoned between the print and the glass, which, he says, no amount of squeegeeing will get rid of, and asks if we can offer any suggestion.—The most prolific source of this trouble is using the gelatine solution too strong, and at too low a temperature. Try a weaker solution, and use it hotter. Also take care there are no minute air bubbles in the solution in the form of froth.

CERAMIC PHOTOGRAPHY.—T. READER. You have been misinformed as regards a patent and a licence being necessary to produce ceramic photographs by the substitution process. With reference to the comparative merits of the substitution and the powder processes, each have their advocates. We have produced good results by both methods, and, on the whole, we prefer the former, though it requires, perhaps, a little more manipulation and skill to work it.

PORTRAITURE BY GASLIGHT.—R. YORKE says: "Would you please give me the name and address of the gentleman in Birmingham who wrote you about two months ago about his inventing an apparatus (gas) for taking photographs at night? I remember he sent you some specimens of his work taken by the light at the time of his communication. I am thinking of trying the light, and should like to communicate with him as to power of light, cost," &c.—The address is J. W. Beaufort, Birmingham.

MOONLIGHT EFFECTS.—AMATEUR asks "how the moonlight pictures seen at exhibitions are obtained?"—In reply: These are, as a rule, neither more nor less than photographs taken in the daytime, the camera pointed towards the sun, which should be low down on the horizon. The direct rays of the sun should not shine into the lens, but be shielded by a cloud, for instance. The plate is very much underexposed, and the print is toned or stained to a bluish tint, to suggest moonlight, or a carbon print is taken on blue tissue.

GUTTA-PERCHA VESSELS.—JAMES G. LOWELL asks if we recommend the use of gutta-percha vessels for containing solutions of silver nitrate for wet-collodion work?—In reply: We do not. Pure gutta percha is said to have no action upon a solution of nitrate of silver; but it was frequently found, in the days when such baths were more generally used, that the impure gum of which they were composed had a most deleterious action upon the solution, and the bath, if it had been kept in a gutta-percha receptacle for any length of time, deteriorated considerably.

GELATINE WET PLATES.—A. E. H. says: "1. I shall be obliged if you will inform me whether it would be practicable to prepare wet plates by using gelatine as a medium instead of collodion, the process otherwise resembling the old wet plate? 2. Would not such plates be of greater speed than collodion plates, and of purer grain than most commercial plates?"—In reply: 1. The process is quite practicable. We are aware of one gentleman who uses "wet" gelatine emulsion, but it is washed. 2. Probably the speed would be greater; but, the higher the speed, the greater the granularity would be.

LENSES AND PLATES FOR STEREOSCOPIC PHOTOGRAPHY.—W. HILL inquires as follows:—"What is the smallest size of plate which can be employed for taking the ordinary stereoscopic views? What focus lenses should be obtained for such work—that is, when one pair only can be afforded? What is the best focus lens to use in the stereoscope itself?"—In reply: The smallest plate that can be used is one $6 \times 3\frac{1}{4}$, but plates $6\frac{1}{2} \times 4\frac{1}{4}$ are more generally employed, since this size is obtainable without difficulty, and if not can be replaced by two quarter-plates used side by side. We should recommend the use of a pair of four or five-inch lenses on the camera, and those in the stereoscope may be similar as regards focus.

LENS; VENUS PAPER.—C. S. asks: "1. If the round, transparent marking in the centre of a plate sent is a 'flare spot?' He found it on six plates exposed in succession with a rapid rectilinear lens, *f*-64. 2. Is it due to a defect that should not exist in one of the highest-priced lenses in the market? 3. Can you inform me where 'Venus' paper is to be procured?"—In reply: 1. The subject chosen seems to us one peculiarly adapted for giving the defect pointed out. It is not a flare spot, but probably a "ghost." Better refer the matter to the makers. 2. Possibly a slight alteration in the separation of the lenses is all that is necessary. 3. Milne & Co., 1A, Ramsden-road, Balham, S.W.

CARBON LENS.—NEMO writes: "Please oblige me in saying what is the cause of carbons 'washing off' in the high lights. Can it be entirely avoided? Also, say what lens I could get to come nearest the following qualifications:—'Great depth of focus,' 'short focus,' 'wide aperture' for enlarging purposes?"—Certainly it can be avoided. There may be several causes for the trouble, but the most general are under-exposure, and the use of too hot water. Insufficient sensitising, or the tissue not being in the best condition, are also causes. The qualifications required in the lens are incompatible with each other. The lenses most generally used for enlarging with are portrait lenses or those of the "rapid" type.

ENLARGING LANTERN.—VANDYKE writes: "I wish to purchase an enlarging lantern, but I know very little about them. Would you kindly give me some assistance by answering the following questions:—1. Should I do better with limelight than oil or incandescent gas? 2. Would my Wray rectilinear, five-and-a-half-inch focus, *f*-8, be a good one for enlarging from quarter-plates? 3. Is ———'s lantern as good as any on the market? 4. Have rectangular condensers any advantage of circular?"—In reply: 1. Theoretically the limelight is best, but there is really very little difference in practice. 2. Yes; if you do not use the lens, usually, supplies with the lantern. 3. Yes. 4. None whatever.

APPRENTICES.—T. T. E. asks: "Am I right in expecting my apprentice to take home some of our orders when they are for customers within a reasonable distance, say, a mile, of the studio? Is this the custom of the trade or not?"—In reply: This depends largely on the actual terms of the indentures, but it should always be borne in mind that an apprentice is not engaged as a drudge, but to be taught the craft, and that the functions usually discharged by an errand-boy can hardly be considered as forming any branch of professional photography. As far as we know, there is no particular custom one way or the other.

FERROTYPES.—J. C. IRWIN asks: "What are the causes of an image not coming on a ferrotype plate? also, how long should it be kept in the silver bath? I kept a plate in for two seconds, then drained it, and put into a carrier and exposed three seconds, which, after being developed, showed no sign of anything. The solutions, I believe, are absolutely correct."—The cause of an image not developing is that the plate was not sensitised. It should have remained longer in the silver bath or until all apparent, greasiness is removed. This will take three or four minutes at this time of year. Three seconds will be too short an exposure unless the lens have a large aperture and the light is very good.

RED LIGHT FOR DARK ROOM.—ENLARGER writes: "Can you give me a cure for headache, or, rather, how to avoid it? I have to work the greater part of the day enlarging on bromide paper, and the rooms are lighted with deep ruby glass. I find, after working four or five hours, I get a bad headache, and I fancy it is caused by the light, as ruby light always tries my eyes very much. Have you heard of the light affecting others?"—Yes, a deep ruby light for long causes great inconvenience with many. However, a ruby light is not necessary for bromide paper. Substitute for the ruby a good sample deep-orange glass. By doing that, the trouble will most likely be avoided. A good orange glass will be perfectly safe with bromide paper.

SIZE OF STOPS.—C. KRONMAN says: "I have recently had a small lens remounted by good makers. Workmanship is excellent, but I cannot agree that the diaphragms have been correctly marked. I enclose card with full particulars, and shall be glad if you will give correct denomination of apertures in your reply column. Only three are marked by makers, but I should like to have value of all four."—If the lens was remounted by a good maker, it may be relied upon that the stops are properly marked. This you can ascertain for yourself by first finding what is the *equivalent* focus of the lens, and then a rule will do the rest. Bear in mind, stops are calculated from the equivalent, and not from the focus as measured from the ground glass.

ELECTRIC LIGHT FOR PORTRAITURE.—"Electricity" writes: "Can you tell me whether portraits taken by the electric light are usually successful, and whether there are many photographers in London who employ it? Would you advise me (a provincial) to go in for it?"—In reply: We are unable to say definitely whether it would be to our querist's advantage to adopt the electric light without knowing more of the circumstances. Certainly there is less necessity for it, generally speaking, in the provinces than there is in London, since the atmosphere in most provincial towns is much clearer. The employment of it might prove attractive as a novelty. Certainly its use is growing in London, and as good photographs can be, and indeed are, produced by the electric light as by daylight.

TESTING A LENS.—SPEC writes: "I have just bought a lens, which seems not to work to focus; at any rate, if I focus ever so sharply, I do not get a sharp negative in every case, although I do sometimes. How can I ascertain if this is so or not?"—In reply: This is very easily done by fixing up, say, a newspaper, in front of the camera in a sloping position so that the bottom is nearer the camera than the top. Then, with the camera level, focus accurately a blot of ink made in the centre of the paper, see that small type close to the blot is as distinct as possible. Before taking a negative, ascertain that the dark slide and focussing screen are in accurate register, and then expose a plate. Should the blot and adjacent type be the sharpest, the lens works to focus; but, should, on the other hand, the type nearer to, or farther from, the camera be that which is best defined, then the chemical focus is nearer to, or farther from, the lens than the visual focus, and an allowance must be made for such in focussing.

SPOTS ON ALBUMEN PAPER, C. C. PAPER, DRYING PLATES.—PHOTOPHILOS. "I fear I am almost abusing your indulgence in so soon again seeking your help, although it will probably cost your great experience but little to give me a reply on the following:—1. I have recently been much troubled with black spots (see sample), which make their appearance sometimes when the paper is dry from sensitising, sometimes only when it is taken from the printing frame. I should be glad to know cause and preventive. 2. You say English-made collodio-chloride will give a good image from very thin negatives, useful perhaps in portraits of young children. I should be glad to know the name of such a paper; also, 3, the name of some paper which prints rapidly, and is then developed, and with which prints similar in tone and surface to those obtained on albumenised paper can be obtained. 4. May the drying of plates be safely accelerated by the use of formol (or formaline)?"—1. The spots are caused by particles of foreign matter that reduce the silver either on the paper when it is floated or settling on it while drying. 2. Try the paper supplied by the Paget Dry-plate Company. 3. The same Company or the Ilford Company. 4. We should say so, from our experience of it. If the plates are put for a few minutes in strong spirits, they may be dried rapidly with moderate heat.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 1868. Vol. XLIII.—FEBRUARY 21, 1896.

Contents.

EX CATHEDRÂ.

The Annual General Meeting of the members of the Royal Photographic Society was held on Tuesday, February 11, at 12, Hanover-square. The attendance numbered about 150, the rear of the room reminding us of the crowded state of the entrance to Drury-lane Theatre on a Boxing Night. Most of those present had, of course, come to witness Mr. Campbell Swinton's demonstration of "photography" with the X rays. The consequence was that the Annual Meeting was forced into the deplorable position of a *lever de rideau*,—it simply played the people in. The farce—for it was nothing more and nothing less—was rattled through in about five minutes, and, various matters affecting the interests and prosperity of a Society numbering close on 600 members having been thus handsomely disposed of, Mr. Swinton proceeded with his admirable demonstration.

* * *

We should have been sorry if the Society had had to forego what turned out to be not only an interesting, but an educational, demonstration and discussion on the photographic subject of the hour; but we certainly think that a strenuous effort should have been made to secure Mr. Swinton's kind help on some other night—say, the Monday or the Wednesday. Before now special meetings, devoted to photographic topics, have been held, so that there were precedents to fall back on. To put it plainly, the Annual General Meeting was, unintentionally we hope and believe, automatically burked. Somebody incurred the grave responsibility of providing for the one night in the year when members of the Society have an opportunity of discussing its position, prospects, and policy, a subject which robbed them of their rights and privileges. Looked at from any point of view, it was a blunder, and a bad one too.

* * *

Mr. S. Herbert Fry, whose address is 12, South-villas, Camden-square, asks us to state that he is authorised, on behalf of Messrs. Thompson & Co., Manchester, to exhibit and explain to photographic societies McKellen's Infallible hand camera, and is prepared to attend meetings with samples and working models. There are no charges for Mr. Fry's attendance.

* * *

Mr. R. H. Ramsay, of The Studio, Lerwick, who is himself a Shetlander, sends us a copy of a lecture to accompany a set of lantern slides illustrative of *A Visit to the Shetland Isles*. The book, which is well written, does not contain a superfluous word, which is more than we can say of most literary productions of this nature. The negatives and slides are the work of Mr. Ramsay himself. We are always glad to note and encourage enterprise on the part of our professional friends, many of whom, in the preparation of lecture sets of local scenery, have an opportunity of profiting by Mr. Ramsay's excellent example.

* * *

The *American Process Review* is the title of a "new illustrated monthly journal," devoted solely to the interests of all branches of process work. It is published in Toronto, Canada, by the Nesbitt Publishing Company, and is edited by Mr. George W. Gilson. We congratulate our brother Editor on his unique and refreshing candour. He says, in a prefatory note, "We have started this journal for two principal reasons: to make money for ourselves, and to be of service to the process-working trade." We wish him success in both ambitions. The first number is nicely printed and turned out. Useful practical articles on *Lenses for Half-tone Process*, and *Dry Plates* versus *Wet*, are among its principal contents.

It was a happy thought on the part of our energetic and enterprising contemporary, *The Stock-keeper*, to organize, in connexion with Cruft's Dog Show, at the Agricultural Hall, an Exhibition of Canine photography. The number, and in very many instances the excellence, of the exhibits surprised us. Professional photographers from all parts of the Kingdom were represented by examples of Canine portraiture, not merely photographically good, but indicative of a well-applied knowledge of the character and peculiarities of dogs, which lifts this kind of work to the level of a specialistic branch of photography that unquestionably admits of lucrative cultivation. Dog portraiture, in fact, is quite an art within an art.

* * *

Dog photography, however, is not the simple thing it sounds. The field it offers for camera work is a wide one, it is true, but the obstacles to success are at least as numerous as the opportunities. Peculiarities of breed and temperament, the "humanness," so to say, of the animals, their moods and instincts as well as their "points," have all to be studied before successful results can be hoped for, and the work obviously demands the exercise of skill and patience in no small degree. Many of the pictures that were shown failed in these essentials; on the other hand, it was pleasant to be able to appreciate the efforts of many professional photographers, who endeavour to portray their canine sitters to their best, that is, to say, their natural advantages. We shall expect this Exhibition to give an impetus to canine photography in particular, and to animal photography in general. A good photograph of an animal is surely more to be welcomed and valued by the "fancy" than a painting, which, at best, is only an ideal representation, more or less, of the original.

* * *

What, for convenience and intelligibility's sake, we must still call the "new" photography, has, during the last ten days, received much attention at the hands of medical men, and elsewhere in the Journal we record a number of instances in which it has proved of great value in surgical cases. The statements that instantaneous photographs have been taken by the X rays, and that an Italian professor has succeeded in devising a means of making the eye sensitive to those "rays," in the sense that it sees through objects which those rays penetrate, seem almost too remarkable to be accurate; but so surprising has been the development of the subject since Röntgen first mooted it, that an attitude of open-mindedness is the only safe one to assume in regard to these and similar revelations.

* * *

One phase of the subject is not without a somewhat comical aspect. We allude to the strange ideas which a great many of the non-photographic public appear to have imbibed with regard to the exact capabilities of the "new" photography. Innumerable journalists are evidently under the impression that hand-camera photographs of one's skeleton can already be taken with the facility attending an ordinary snap-shot. A more serious matter, however, is the fear which a professional photographer of our acquaintance assures is a real and growing one with many would-be sitters, that the operation of having one's photograph taken is accompanied by the risk that the lens and the dry plate at any time may "take it into their heads" to neglect our integuments and yield an unlooked-for and unwelcome representation of our "innards."

A notable addition to London photographic studios was made on Monday last, when the well-known photographer, Mr. Lyddell Sawyer, inaugurated the Dudley Studio, 219, Regent-street. The studio replaces one formerly situated on the same premises, with which the name of Samual A. Walker was for so long associated. The success which Mr. Sawyer has met with at Newcastle, the high position he has won in his profession, and his unquestioned artistic powers, fully warranted him in the boldness and decisiveness with which he has entered into competition with his London brethren, and we have every confidence that the Dudley Studio will speedily compel success.

* * *

The dingy old rooms have been entirely demolished, and, in their place, a fine suite of apartments has been constructed. A short, artistically contrived flight of stairs leads up to a noble reception-room, whence access is readily permitted to waiting-rooms, dressing-rooms, and studio, the latter commanding an uninterrupted north light, as it is out of proximity of lofty buildings; the electric arc light is also available. All the rooms are furnished and decorated in a sense of refined elegance and luxury, adorned with many examples of Mr. Sawyer's work, and are at once harmonious in colour and tastefully appointed down to the smallest detail. It has taken Mr. Sawyer many months to get his handsome studio completed, and we shall evade the difficult task of describing it by saying that he appears to have "let himself go" in the successful endeavour to give London possibly the most charming photographic studio it has yet possessed.

ANTHION.

Under the above descriptive title is introduced a new and useful auxiliary to the every-day work of the photographer. It purports to be a perfect eliminator of the last traces of hypo, or, to speak correctly, thiosulphate of soda, whether in the gelatine film of the negative or the paper print. Upon carefully testing this, and following exactly the simple instructions issued with each bottle, its claims as an effectual destroyer of the fixing agent are fully borne out. Anthion is a granular crystalline salt, exceedingly rich in oxygen, and sparingly soluble in water. Its solubility, in fact, is only one in two hundred, and the solution, if kept in a well-corked bottle, will be good for a month, but is slowly decomposed, even at ordinary temperature, giving off oxygen or ozone. It is presumably the persulphate of potash ($K_2S_2O_8$), and is thus a salt of persulphuric anhydride, the corresponding acid to which has never been isolated. According to Watts, potasslum persulphate is obtained by passing a current of three to three and a half ampères for some days through a saturated solution of the acid sulphate of potash ($KHSO_4$) contained in a platinum dish, wherein is suspended a porous cell containing dilute sulphuric acid. The platinum dish stands in one of copper, through which a stream of cold water is allowed to run, and which is connected with the battery so that the platinum dish forms the anode. The kathode consists of a stout platinum wire immersed in the sulphuric acid. The granular salt, which gradually forms, is collected and dried. Potassium persulphate is decomposed by heat giving off SO_3 and O, whilst KSO_4 remains behind. Silver nitrate gives no precipitate at first, but a black silver oxide is afterwards thrown down, and the solution becomes acid. Potassium iodide is decomposed with the liberation of iodine, whilst

litmus and turmeric are bleached. By these reactions it will be seen that anthion is possessed of very similar properties to hydrogen peroxide.

Following the instructions, eighty grains of anthion were dissolved in forty ounces of lukewarm water. A half-plate negative, after fixing, was washed in about a pint of water contained in a porcelain dish. After five minutes' soaking, the plate was transferred to a second dish containing eight ounces of anthion solution, and allowed to soak, with occasional rocking, for another five minutes. This operation was repeated with fresh water and anthion solution, when it was found that every trace of hypo was removed from the plate. The test given in the sheet of instructions is to add a few drops of a twenty-grain solution of silver nitrate to an ounce or so of the last washing water, when, if the white precipitate which forms turns yellow, the hypo is not all eliminated. A more satisfactory and easy test is the iodide of starch. For this purpose a piece of paper sized with starch is brushed over with a very dilute solution of iodine in water. A violet colour is produced, which is instantaneously bleached if the slightest trace of hypo remains in the water. A drop from the corner of the negative, after about five minutes' washing from the last dish, was allowed to fall on the coloured paper, and the absence of hypo was shown by the violet colour remaining unaltered.

Of course, the fixing salt can also be discharged with equal facility from prints, and in this case several may be manipulated at the same time and a similar test employed. In the case of prints, however, it will be found handy to have a small bottle of dilute iodine solution at hand, when, by applying a drop to a corner of the print at the back, using a very small brush, or even a match, for the purpose, the violet stain characteristic of iodide of starch will appear if the hypo has been discharged.

It will be understood, however, that the instructions described are only for extreme cases, where the supply of water is very limited. If running water is available, of course it would be advisable to utilise it; but even then a short immersion in anthion makes the absolute elimination of the hypo a matter of certainty. In that case, even a little flowed over the washed negative, and allowed to soak in for a few minutes, will be found effectual. Especially when a negative has to be afterwards intensified with mercury, anthion will be found to be of great service, for then the least trace of hypo in the film will cause the well-known yellow stain, which cannot be eradicated.

The advantages of anthion will be readily appreciated, for it is, in its crystallised state, a stable salt, ready for instant use at any time, whilst nearly all the hypo eliminators hitherto employed are of varying composition and uncertain in their action.

Prohibited Sale of Paintings.—It is often said that "they manage things better in France." So they do, some things. Here is one of them: It appears that there is a law in France which prohibits the sale of any new article by public auction, except in the case of bankruptcy. For some time past there has been a daily sale, by auction, in Paris, of paintings in showy frames. The "pictures," it is said, are produced by a division of labour, one artist painting the skies, another the trees, and another the figures, and so on, at a few francs a day. The business proving so lucrative in the capital, it was being extended to the provinces. It is now, however, determined, in the interest of the natives, and artists, to put the law into force, and stop the sale of new paintings by auction. It is somewhat a pity we have not a similar law here, to put a stop to the sale of the miserable daubs, in showy gilt frames, at some of the mock auctions in London, where the unsuspecting public, mostly from the country, are so often taken in.

The North Pole.—During the past week the daily press has been teeming with reports that Dr. Nansen has really reached the North Pole—and doubts as to the fact. To get to the Pole has been the ambition of many expeditions during the present century, but up to the present—unless Dr. Nansen has got there—they have ended in failure. In the programmes of all the Arctic expeditions of late years has been photography, and a very complete equipment has always been announced as a feature in the paraphernalia taken out. When the expeditions have returned, although they have failed in their main object, we have heard little, and seen less, of the photographic results obtained, if any, in the extreme northern regions. Although the North Pole, or any other predetermined-upon point, was not reached, one cannot but suppose the photographic appliances were brought into use *en route;* but with what result? What photographers are interested in is, to learn how dry plates and films behave as to time of exposure and keeping qualities under extreme conditions of prolonged cold. It is to be hoped that we shall learn something in this direction from the Nansen enterprise on its return.

The Annual Guildhall Fine Art Exhibition.—The Sunday afternoon opening of this Exhibition has again been a topic of animated, almost personal, discussion with the Court of Common Council. A certain proportion of the Council are strenuously opposed to the Sunday opening, and some members regretted that the Ancient Corporation should be "sullied" by the Sunday opening; one read a verse from the Bible, and the result was to raise a laugh. In the end, on the vote, ninety-two were in favour of giving those who could not see the pictures on other days the opportunity of seeing them on Sundays, while sixty-nine were against it. Mr. Alderman Treloar, who has always been the champion of the Sunday opening of this loan Exhibition, is to be congratulated on his majority of twenty-three; many wish it were larger. The figures quoted at the meeting show that, on the thirteen Sundays the last Exhibition was open, 19,720 people visited it. Photographers who cannot get the time during the week to see this show will again have the opportunity of doing so once more on Sundays. It should be borne in mind that this Exhibition is of pictures loaned from the best private collections, and it is the only opportunity the general public have of seeing them.

A Novel Way of Exhibiting Photographs.—A very simple and inexpensive, though ingenious, way of displaying photographs, where wall space is not available, was that adopted by Mr. Welford, with the assistance of Mr. Fortune, at the Photographic Club and at the London and Provincial recently. As the system will be very useful to those societies which have perhaps annually a one-day show of members' work, and only require an extemporary arrangement, the plan deserves more than the notice it gets in the brief society reports. One of its great advantages is that any one who can use a hammer, nails, and a saw can construct the whole affair in a few hours. The idea is, we believe, Mr. Fortune's. Strips of wood, about a couple of inches wide and about half an inch thick, are nailed together to form frames of a convenient height and width, with one or two cross bars, which serve the double purpose of strengthening the frames and to suspend the pictures from. Strips of wood, suitable for the purpose, are stocked at most timber yards. When a number of these frames had been constructed, Messrs. Welford and Fortune, it was mentioned at the Club, were at a loss as to how they should be supported. Mrs. Fortune, however, came to the rescue by suggesting that they should simply be hinged together with webbing, like the domestic clothes-horse, and this was done. The whole affair is nothing but a many-leafed clothes-horse, which is self-supporting. Many thanks are due to Mr. Fortune's better half for the suggestion.

Adulterated and Impure Chemicals.—On Friday last a pharmaceutical chemist was, at the Marylebone Police-court, mulct in a penalty of forty shillings, and two guineas costs, for selling white wax adulterated to the extent of thirty-eight per cent. with paraffin. The defence put forward was that there were two kinds of wax, one containing paraffin, and the other pure beeswax. It was stated that it was the former mixture which was supplied to the public, while the latter was used for pharmaceutical preparations. Since the days of the wax-paper process, wax is but little used in photography, except for "encaustic pastes," and for waxing glass plates from which collodion films have to be stripped. For either of these purposes an adulterated article, such as that in question, would be totally unfit. Although the Poisons Act gives pharmaceutical chemists the monopoly of vending certain chemicals, it does not exempt them from the attentions of the Sanitary Inspector, and this is not the first time that "duly qualified" chemists have been fined for selling impure materials. By the way, when wax is required for photographic purposes, it is better to buy the best yellow beeswax, for, as a rule, that is a purer article than the more expensive white wax. If it can be obtained from a farm house where bees are kept, its purity can be relied upon.

Some little while back we ran out of cyanide of potassium, and wanted some at once. We repaired to a pharmaceutical chemist in the neighbourhood, who makes a display of cheap apparatus and photographic chemicals, when, after going through the prescribed formalities, we were supplied with a couple of ounces, for which we were charged the moderate price of one shilling. This turned out to be about the most impure sample of cyanide that ever passed through our hands. It required quite three times the quantity to redissolve the cyanide of silver formed from a given weight of the nitrate that our previous exhausted stock did, and which cost two shillings a pound. Commercial cyanide of potassium always contains some carbonate of potash, but it is priced wholesale, according to the proportion of cyanide it contains, and this varies from thirty per cent., or less, to ninety-five per cent. If the sample we were supplied with had been bought by the Sanitary Inspector, there is very little doubt that the vendor would have got into trouble.

Roughening the Surface of Glass.—The question of roughening the surface of glass has recently been referred to, hydrofluoric acid having been one of the means recommended, while, in the case of a negative the back of which it is desired to permanently "frost," as some term it, emery powder, worked with a wetted pad, has been said to be superior. If hydrofluoric acid be chosen, the gas should be employed in preference to the liquid, as it gives a surface of greater obscuration. When mechanical abrasion is made use of, it may be noted that the kind of glass to be treated greatly influences the amount of labour required. In a paper on the "Laws of Attrition," recently published in the *Royal Society's Proceedings*, we find, among a variety of other substances whose "attrivity" is given, that, taking quartz as 4, English plate glass is 5·7, and French plate glass 8·8, marble being 100.

Dark-room Illumination.—The last two or three years have seen, in the search after suitable orthochromatic screens, investigations into the properties of such a great variety of tinctorial substances, as regards their power of arresting various portions of the spectrum, that we think the time has arrived when some enterprising manufacturer might come forward, and make, on a commercial scale, a series of coloured screens, either of gelatine alone, or of glass coated with a series of suitable substances for arresting any selected portion of the spectrum. It has been shown that certain of the modern dyes are absolutely opaque to some particular rays; the gelatine sheets might be labelled in regard to the special portion of the spectrum which would not pass through, or, what might perhaps be more in favour with the non-scientific photographer, the makers could, in concert with an investigator familiar with the subject, vend one screen as being most suitable. Of course, a maximum of luminosity in combination with comparative safety would be aimed at. It is quite certain that the glasses and screens at present in popular use are selected mainly empirically. Some are excellent, some risky, some absolutely dangerous.

In connexion with this subject we may note a substance which we believe is new for the purpose, and which possesses valuable properties. We refer to naphthazarine, which, when dissolved in alcohol, will, according to E. Wiedemann and G. C. Schmidt, arrest green, blue, and violet rays. As this would leave the little active orange and the luminous yellow rays to pass through, it is possible that this substance alone might answer the required end. But it is one only of a large number which, alone or in combination, are capable of forming a screen as nearly perfect as possible. We commend the idea to those whom it may concern.

Acetylene.—It is quite evident that we have by no means heard the last of this illuminant. The newspapers "boomed" it to such an extent upon the first introduction on a commercial scale of the new mode of production, while there is now so little heard of it, that it might be supposed almost to have died a natural death, except for experimental purposes. It only needs the gas-compressing firm to send it out in cylinders to at once establish its use on a firm footing. It is remarkable that they have not already done so. Already, however, some firms are catering for possible consumers by the manufacture of gas-holders, and it is highly probable that others will follow suit.

There has been much loose writing upon the cost of the calcium carbide employed to produce it. It is credibly stated that at Spray, in North Carolina, it is made (by the passing of an alternating electric current through a mixture of lime and powdered coke) at a cost of twenty dollars a ton, that is, at the rate of about four shillings per hundredweight. As one ton of the carbide will produce 11,000 feet of the new illuminant, a fair idea of the comparative cost may be formed. This, however, must be qualified, if comparison with ordinary coal gas be made, by the recollection that the chief part of the charge of the latter is for "delivery at one's doors," so to speak.

But this is not all. We now read that the power from the Niagara Falls is to be utilised, works having been erected on the banks, which were expected to be in working order about the middle of this month, and to be able to produce the calcium carbide at ten dollars a ton—some papers state five dollars. Possibly the latter may refer to the actual manufacturing cost of production, and the former to the selling price.

The Röntgen Rays.—Variations upon the originally published process, and a search for similar effects from other sources continue to be made in every direction by investigators of every calibre. Lord Blytheswood, who explained at a public lecture how he nearly discovered the Röntgen rays some years ago, has succeeded in obtaining dry-plate images through "opaque" bodies without the use of either a coil or a Crookes' tube. He has a very large and powerful Wimshurst electrical machine, worked by a one-and-a-half horse-power engine. It gives a torrent of sparks a foot and a half or two feet long. Arranging his apparatus in a manner that need not here be explained, he obtained images upon a plate enclosed in the dark slide, and wrapped in four folds of black velvet. (Details may be found in last week's *Nature*, page 340.)

In contradiction of those who have stated that the light of the electric arc contained rays acting like those of Röntgen, M. Moreau, in the *Comptes Rendus* of the week before last, distinctly shows how the two radiations differ. A powerful arc lamp, of twenty ampères, exposed at a distance of about sixteen inches to an ordinary dry plate, wrapped in several thicknesses of black paper, showed no

result of light action whatever when developed, though, under the same circumstances, the Röntgen rays acted strongly.

M. Moreau used no Crookes' tube, but only the brush discharge from an induction coil. When the case holding the sensitive plate was placed normally to the brush, no action took place; when placed parallel to it, strong, clear negatives were produced. These results may throw much light on some of the recorded experimental failures.

CONTINENTAL STOPS AND THEIR U.S. EQUIVALENTS

PHOTOGRAPHERS are frequently troubled by the Continental nomenclature of the stops, and wish to know the U.S. equivalents for them. The method of finding this out is very simple. All that is necessary is to divide *f*-4 by the ratio to be converted, and square the result. Example: required the U.S. equivalent of *f*-9:—

$$\frac{f}{4} \div \frac{f}{9} = \frac{f}{4} \times \frac{9}{f} = 2{\cdot}25;$$

the square of 2·25 is 5·06, the U.S. number required. The following is a table of the Continental stops more commonly met with, and also the Continental values of the U.S. ratios:—

Ratios. *f* divided by	Continental Values.	U. S. Values.	Ratios. *f* divided by	U. S. Values.	Continental Values.
4·5	512	1·26	2·828	·5	1250
6·3	256	2·48	4	1	625
7	204	3·06	5·66	2	312
7·2	193	3·24	8	4	156
7·7	168	3·71	11·31	8	78
9	128	5·06	16	16	39
12·5	64	9·77	22·6	32	20
14·5	47	13	32	64	9·77
18	32	20	45·3	128	4·88
25	16	39	64	256	2·44
36	8	81	90·5	512	1·22
50	4	156	..	..	..
71	2	315	..	..	..
100	1	625	..	..	..

To find the *f* ratio for the U.S. values, multiply the U.S. value by 16, and the square root of the product is the required ratio. Example:—What is the ratio of U.S. 32? 32 multiplied by 16 is 512, the square root of this is 22·6, the ratio required.

To find the *f* ratio for the Continental stops, multiply the reciprocal of the square root of the Continental value by 100. Example:—What is the *f* ratio of the Continental value 16? The square root of 16 is 4, the reciprocal of 4 is ·25, which multiplied by 100 is 25, the ratio required.

Note:—The Continental ratios of 512, 256, and 8, ought to be 4·4, 6·25, and 35, respectively. The figures in the list are those extracted from Continental opticians' catalogues. EDWARD M. NELSON.

ON THINGS IN GENERAL.

WHAT profession or trade is there upon which Trilbyism has not left its mark the last month or two? That photography should receive the imprint is not to be wondered at, for how much would the general public know of the Haymarket exponents of the cult but for the aid of the camera worker? Every professional owes a debt of gratitude to Mr. Turner for the way he shows and explains to them how to nurse their productions to profitable ends. Why should the newspaper man have all the pickings, and the poor professional see his productions used to enhance the interest and profits of the illustrated journals? The reason is twofold. In the first place, the photographer whose works have never been exploited is so proud at the sight of his name in a paper which is circulated everywhere that he is quite content with the advertisement. This is mere rubbish. I know many professional photographers, and they all say they can never trace a penny increase in their business to any such source of publicity. The second reason is the idea that prevails among the great majority that the Copyright Union minimum of half a guinea is also a maximum. They don't read what is put before them. They should learn that the market value of a copyright permission is unlimited except at the half-guinea end. The popularity of the subject combined with rareness or difficulty of obtaining a negative are the governing factors. The papers are just as anxious to obtain interesting photographs, as to be first in the field with news, and equally to pay—that is, when they can't get them for nothing.

If the now famous Röntgen ray sciographs had been made copyright, a very large sum could have been obtained for sole permission to use them as soon as the rays were "boomed." And what a boom there is and has been! It is marvellous how the public will have the last new thing in science: the less they know about it the greater their interest. Colour photography is quite left out in the cold. If it had not been for Röntgen, the last new paragraph about the Chicago experimenters would have furnished pabulum for scores of leading articles on a subject which has hitherto been one of perennial interest. But, so far, not a line seems to have been written. A feeling appears to be gaining ground that photography, as applied to Röntgen's prints, is an entire misnomer: that electricity, not light, is the factor. It may be either or both, for all we know, at present; but we do know, from the consensus of experimental product, that the exhibited results are, in the main, legitimate, and free from sophistication, though I must call attention to one print—a hand, one of the fingers of which is ringed. The process-block print represents the flesh *outside* the ring, and not as a crease where the ring has become embedded in the course of time, for the contour of the fleshy part of the finger is unbroken. The Röntgen prints are essentially legitimate: but what are we to say of Mr. W. Ingles Rogers's eye pictures? Briefly, he fixed his gaze for a long period on a postage stamp, then held a plate in a similar position as regards his eyes, and gazed upon it equally intently and long. On developing the plate, a distinct image of two postage stamps appeared, the theory being that the original retina impression was of such a character as to be able to emit actinic force, and sufficient to impress a plate. I should be sorry to brand any alleged scientific experiment as worthless, but I may at once say these eye prints cannot be admitted as genuine unless a reasonable explanation of certain difficulties is offered. Thus, firstly, why did the eyes produce two images? If they retained the position they had during the gaze on the stamp, there should be only one image instead of two, for the optic axes would converge to a point, and, if the retinæ were luminous, their luminosities would be focussed on that point. The reply may be that the sensitive plate was in the dark (he does not specially say it was not, in the case of the stamp) while being gazed at. It is known that, when a person is asleep, his eyes are usually focussed for distant objects, and it is generally the case that the focussing of the lens of the eye and the greater or less converging the axes are almost involuntary and synchronous; hence, if Mr. Ingles Rogers's eyes were in the dark, their axes might be parallel, and then, of course, two, if any, images would be given, and the focussing would be for distance. This, the only feasible explanation, is open to the objection that, if the eyes were focussed for distance, the issuing rays would form no image at all, as they would be parallel. Mr. Ingles Rogers is on the horns of a dilemma on these counts alone. Let us grant that the eyes were not focussed for distance, and that, by some inexplicable means, he can turn his eyes outwards, and keep them so and immovable for a third of an hour, he has to face another difficulty. If retina, eye, and plate were similarly placed as retina, eye, and stamp, the image of the stamp ought, by the laws of conjugate foci, to project its luminosity on to a space exactly the size of the original stamp, whereas, in the view printed, it is about half a centimetre high, or one fifth of the true size. I don't think Mr. Ingles Rogers will be heard of again.

Messrs. Haddon and Grundy are giving us the results of some more of their invaluable experiments. With regard, however, to the solubility of silver in hypo in the presence of air not having been previously observed, it is very probable that they are correct, so far as a scientifically expressed statement is involved; but I think many

photographers must have been practically acquainted with the fact, seeing that a negative fresh from the hypo reared up to dry will lose very considerably in strength in twenty-four hours. Of course, this is not a proof that metallic silver has been dissolved, though it is probable that such is the case.

What a huge pother has been created over a simple matter—chemists and the sale of poisons. The matter lies in a nutshell, and is really outside any real disputation. The supreme legislature of this country, with the best advisers to help them, devised a scheme to diminish the risk of poisoning by misadventure or otherwise, and passed an Act rendering it illegal for any but a man who had passed a certain examination to sell certain poisons. The men who pass these examinations are those who keep chemists' and druggists' shops, and the only object of passing the examinations is to enable them to sell these poisons, either in making up prescriptions or open sale. Can any one say that it is fair to these traders, who have to go to great expense and give much time to qualify for the examinations, to render this perfectly nugatory, and wasted money and time, by permitting the sale of poisons by any other than such qualified men? Let us all be reasonable and just over the matter. Get the law altered, if desirable; but don't throw a great burden on an honest trader and give him no benefit from it. Incidentally one writer says he cannot get as pure chemicals from a "chemist" as from a photographic dealer. It is mere rubbish to talk in that strain.

We have had some really valuable hints about dark-room illumination of late, which, read with judgment, should be of aid to almost every one. I say with judgment advisedly, for an amateur was heard to say the other day that all he could learn from recent talk about dark-room lights was that yellow and other windows would fog, and that the proper light to change plates by was an ordinary unshaded candle.

This remark was probably brought about by reading the well-worn dictum that there is no such thing as a "safe light, and it is all a question of time." No photographer of scientific attainments would doubt the truth of this dictum, which, expressed in other words, is that, give it time enough, a gelatine plate is sensitive to all luminous (not to speak of invisible) radiations. This being, as it undoubtedly is, absolutely true, I am constantly marvelling at the crass stupidity of some writers who assert that orthochromatic effects cannot be obtained, even by the aid of screens, on ordinary plates.

I will conclude my lucubrations by calling attention to the cool impertinence of a correspondent "Amateur (London, N.W.)," who wishes to know if it is not unfair for a professional to charge a stiff price "to one who knows the cost of everything used" for taking a first-class negative that he, the amateur, may print copies from for his friends? Putting aside the fact that this amateur is extremely unlikely to know anything whatever of the cost to a professional of taking a negative, one is inclined to ask whether he ever grumbled at having to pay a guinea for a first-class prescription from a first-class doctor when he well knew the cost of his ink and paper?

FREE LANCE.

ELECTROGRAPHY.

MOST of the periodicals have given some notice on the subject of the "new photography" (so misnamed) based upon the alleged discovery of so-termed "Röntgen rays." This has been quite a mania. I have already pointed out in this JOURNAL that distinct images derived from electric induction have been obtained by Professor Draper through intervening opaque substances more than thirty years ago. The recent impressions appearing in support of the existence of such "new rays" are mere hazy shadowgrams. The advocates of newly discovered rays are in a state of perplexity concerning them. They are stated as not refrangible, and therefore not in the spectrum, but somewhere outside, and so cannot belong to it; therefore the lens maker is unable to utilise them optically for picture-making, and consequently results must be more imperfect as distance is increased. The most distinct impressions are those in which prints have been obtained with the object in close proximity to the sensitised surface. The exciting agency is electric induction. When an object is placed in the field of an electric discharge, certain parts, either external or internal, of various degrees of density or conductivity either facilitate or obstruct the passage of the radiations, and so cause a difference in the impression that will result in a picture of the structure.

Improvements may be advanced in two directions. First, by concentrating the energy of the electric discharge. Continuous sparking is not so proportionately energetic; a quiet, continuous current is more productive. For this a simple printing frame may be constructed from a wooden box, the interior of the lid to be either insulated or not. This should be furnished with a pendent group of sharp pin points, and the bottom similarly provided with receiving points. On connecting the lid with the conductor of a Wimshurst machine in operation, a quick, non-luminous discharge will take place between the points, and the object to be copied is superposed upon the sensitive plate, both being laid in the closed box.

Secondly, as to the chemical nature of the sensitive plate. Although unquestionably the presence of weak electrical currents will affect ordinary photographic plates, yet there may be materials that are relatively insensible to light, but highly sensitive to electric influence.

Starched paper sensitised with potassium iodide is usually employed for electric indications, as in the ozometer; or, if a point emitting electricity is traced over the surface, a blue line will follow from the liberation of free iodine, which colours the starch. This is a common test for either. The decomposition of the iodide is probably due to the liberation of a minute trace of nitric acid from the air, which always accompanies a free electric discharge. On account of its blue colour this impression is not well adapted for printing from, and is rather fugitive. The discovery of a compound that is highly sensitive to free electric radiations, and which can be developed to a dark tone, and be duly fixed, is quite within the province of the photographic chemist.

I now end the subject. I adhere to the free electric induction theory, which alone accounts for every result, and leave the "new ray" advocates to prove some separate influence, if they are able to do so, the evidence of which at present is very unsatisfactory.

F. H. WENHAM.

THE "NEW PHOTOGRAPHY."

INSTANTANEOUS photography with the X rays.—In the experiments at Toronto University, Herr Röntgen's X rays are focussed downwards by a glass bell over the Crookes' tube, thus enabling instantaneous photographs to be taken. Trinity College, Hartford, reports the appearance of photographic halation, indicating a reflection of the X rays. Mr. Edison believes that some experiments upon which he has been engaged indicate a method of hardening and tempering aluminium to the quality of steel.

LAST week, at Queen's Hospital, Birmingham, a successful operation was performed with the aid of the Röntgen rays. A fortnight ago, a Mrs. Berry ran a needle into her hand, and the hand became much swollen. Dr. Hall Edwards took a photograph of the hand, and the needle was clearly seen. The operators extracted it with the aid of the print, and speak highly of the assistance it had been to them.

Dr. McKenzie Davidson, of Aberdeen, has utilised the Röntgen rays for the removal of a needle from the foot of a patient. The needle was only one inch long, and when its exact position had been detected by means of shadowgrams obtained by the rays, it was extracted by the medical gentleman.

DR. J. J. THOMSON has discovered an even more delicate test for the presence of these rays than the photographic plate, as he finds that, if a metallic electrically charged plate be perfectly insulated and even bedded in paraffin, ebonite, sulphur, or other non-conductor, and then exposed to Röntgen's rays, it rapidly loses its charge, whether such charge be positive or negative. This fact is particularly interesting, as showing that all substances through which these rays are passing become for the time being conductors of electricity. It has been asserted by other observers that it is by no means necessary to provide oneself with a Crookes' tube and the necessary electrical apparatus, as the light from a few inches of burning magnesium ribbon, and even from less intense sources of light than this, evolve certain rays which are also capable of passing through opaque bodies, such as wood, and impressing themselves on a photographic plate beneath.

MUCH attention is being given at Rome to the discovery made by Professor Salvioni, of Perugia. An instrument called a cryptoscope adapted

to the eye enables the vision by means of the Röntgen rays to penetrate opaque bodies. It is stated that Professor Salvioni is perfecting his discovery, which will acquire as much importance as that of Röntgen's itself. The experiments hitherto made are of the most conclusive character. The retina of the eye is impressed by means of the cryptoscope exactly in the same way as a photographic plate.

The first practical demonstration in a London hospital of the Röntgen discovery in regard to a living subject was given last week at St. Thomas's Hospital, before the members of the Medical and Physical Society. Dr. Mackenzie, one of the assistant physicians, presided, and was supported by a large gathering. The experiments were conducted by Mr. A. F. Stanley Kent, late demonstrator of physiology, who briefly described the new process. The first experiment was a most interesting one to those present. The subject was a young medical student of St. Thomas's, who, during the day, had had the misfortune to break one of the fingers of his right hand. This hand was photographed, and the plate when developed showed the exact position of the fracture in the bone of the finger.

Dr. Carlton Simon, of New York, a pupil of Charcot, has, it is said, stolen a march on Mr. Edison by inventing a process which has enabled him to photograph his own brain. For three years past Dr. Simon had been working quietly towards his end. Reports of Professor Röntgen's discoveries and Mr. Edison's experiments hastened his researches, and last week his labours were rewarded by results which, though still incomplete, were fairly satisfying. An ordinary camera with platinum plates (*sic*) was employed. Dr. Simon is not yet prepared to explain his process in detail. In making a statement to an interviewer, however, he said: The rays I use in conjunction with sound, and they are electric rays so far as the light is concerned. I produce the effect by attraction of the light and propulsion through the brain substance. At the time of photographing the whole internal chamber of the brain is illuminated. My discovery is not consequent on the application of the cathode ray to photography.

The *British Medical Journal* publishes the second part of the report by Mr. Sydney Rowland on the application of the new photography to medicine and surgery. New light must be thrown on the problem of the tube and its adjustment to the current before the new method can be accepted as a means of clinical diagnosis. A photograph of a human foot by Mr. Rowland shows very clearly the nature of the bone changes and the atrophy produced by the wearing of tight boots; and there can be little doubt that the new methods, if they can demonstrate positively the injurious changes wrought in the texture and structure of the human body, will make more powerfully for health than any agency we have previously known.

From inquiries made at some of the principal metropolitan hospitals, it appears that preparations are in progress at several for experiments with the Röntgen rays. Dr. Bellington Smith, Surgical Registrar at Guy's Hospital, stated that in the electrical department active preparations were being made in the direction of constructing the apparatus necessary to conduct the experiments by the new process. Considerable difficulty had been experienced in getting vacuum tubes of sufficient strength for the purpose, but it was hoped the apparatus would be quite complete in a few days' time, and experiments would be made as suitable cases came forward. As to the invention itself, Dr. Smith said he thought it would be extremely useful in determining the position of a needle embedded in the hand, a class of accident that was very common in connexion with public hospitals. It would be a benefit also in assisting physicians to find out the position of a new or old fracture of the bones of the leg or arm; and, further, it would prove of great help in finding the position of a bullet in limbs of the body. About a year ago, a man was admitted to Guy's on his return from Africa, where he had received a wound in the head from a bullet, part of which remained in his skull, and very great difficulty was experienced in extracting the missile. In such a case as this the new invention would have been of great service.

Mr. A. W. Porter, the Lecturer on Physics at University College, said he had been repeating a great deal of Professor Röntgen's work, both as regarded verification and also the extension of it. There seemed to be some hope of settling the question soon as to the nature of the rays with which the photographs were taken. He had been successful in obtaining some of the "sharpest" photographs under the new process that had yet been procured in England, and probably with the least power and with the shortest exposure. His maximum time for exposure was two and a half minutes, and he had obtained some very excellent results. Attempts to take thick objects, such as the vertebræ, had failed up to the present, owing to the radiation becoming diffused through the thick obstacle, and probably, owing to this latter fact, the use of the new process in surgery would be of a limited nature. In conclusion, Mr. Porter said that dozens of medical men had visited the laboratory to witness the experiments, and very great interest was being taken in the matter.

Professor O. J. Lodge, at the University College, Liverpool, the other night, is reported to have said it was now proved that Röntgen's rays were not streams of electrified matter, but it was quite possible that some crucial experiment might soon be made which would set at rest the present doubts as to the merit of the remaining hypotheses on which the discovery was to be explained. If the rays were ultra-violet light, high up in the scale of the spectrum, it was probable, judging from their effects, that the rapidity of their vibration was a million times greater than that of ordinary light, or about as much more rapid than light as light was more rapid than sound. There was some evidence in favour of this, since the rays were able to discharge negatively charged bodies. At present, however, he thinks the rays are longitudinal waves in the ether. If so, the discovery would open up a department of physics as large as light, sound, or electricity. Professor Schuster pointed out the fact of Newton having held that fine particles of light could pass through opaque substances. It was now established that light and sound were transmitted with differing speeds through varying substances. Here, however, were rays which seemed to go at almost the same speed through everything, and which were not acted upon by a lens. There was a feeling on the part of physicists that in these rays we were on the eve of a discovery of something which links the hitherto isolated force of gravity with that of the higher forces of nature.

REPORT OF THE PLATE-SPEEDS COMMITTEE

[Royal Photographic Society.]

To the Council of the Royal Photographic Society.

Your Committee have to report that, appointed by Council on April 25, 1894, *to consider and report upon the best method of determining plate speeds*, they have given the matter their consideration.

The difficulty which they encountered at the very outset of their work lay in the apparent impossibility of defining the phrase *the speed of the plate* in a sufficiently explicit manner, at the same time keeping the definition wide enough to embrace what is usually meant by the term.

Your Committee found that practically four systems of plate-speed measurement were before the public, which might be described as those

of:—Captain Abney, Messrs. Hurter & Driffield, Mr. Spurge, Mr. Warnerke (there are also two systems recommended in 1889 and 1891 respectively by the International Congress at Paris and Brussels) and a series of experiments were undertaken with a view to ascertain whether these four systems, differing widely in method, yielded accordant or discordant results. It was soon thought necessary, for the purposes of comparison, to lay down a definite constant development, and your Committee agreed that their experiments should be conducted by developing at a temperature of 70° Fahr. for four and six minutes with a developer of the following composition:—

Pyrogallol	2	grammes or	2 grains.
Potassium bromide	0·5	,, ,,	0·5 ,,
Anhydrous sodium carbonate	6	,, ,,	6 ,,
Crystallised sodium sulphite	20	,, ,,	20 ,,
Water	437·5 c. c.	,, ,,	1 fluid ounce.

Working under these conditions, two plates of different make were tested by the Committee with a view to ascertain their relative speed by various methods, and it was found that all these gave identical results except one, the speed ratio of the two by three methods being given as 5 : 1, by a fourth as 9 : 1.

Further experiments using the same developer, but, instead of developing for a fixed time, continuing the development until fog appeared, showed that this concurrence in the case of the two plates was probably accidental, since the readings of six plates differed widely, as shown by the table below.

The vertical columns give the various readings of each of the plates 1, 2, 3, 4, 5, and 6, the horizontal columns give the readings by any one experimenter of the set of plates, the speed of plate 1 for purposes of comparison in each case being taken as 100.

Experimenter.	Plate number.					
	1.	2.	3.	4.	5.	6.
A	100	12·3	65	0·19	23	14
B	100	9·7	33	0·23	10·5	10·5
C	100	12	20	1·7	14	6
D	100	18	45	2	40	12
E	100	14	25	2	14	10
F	100	16	31	2	31	10
G	100	31	50	0·16	31	12·5
H	100	20	33·3	0·39	28·5	5·26

From this it will be seen that even the order of their rapidity differs by various systems, the order being as follows (the fastest being put first):—

A ... ... 1 . 3 . 5 . 6 . 2 . 4.
B ... ... 1 . 3 . 5 . 6 . 2 . 4.
C ... ... 1 . 3 . 5 . 2 . 6 . 4.
D ... ... 1 . 3 . 5 . 2 . 6 . 4.
E ... ... 1 . 3 . 2 . 5 . 6 . 4.
F ... ... 1 . 3 . 5 . 2 . 6 . 4.
G ... ... 1 . 3 . 2 . 5 . 6 . 4.
H ... ... 1 . 3 . 5 . 2 . 6 . 4.

Your Committee would emphasise the fact that these differences were obtained with the use of identical developers.

Your Committee have to report that, so far, they cannot see a way to recommend any system of speed determination without the employment of identical development both for the test and for the subsequent use of the particular plate in question.

Your Committee have also to report that for reproduction by photography, where accuracy is required, they are unable to see that exposures described by Messrs. Hurter & Driffield as belonging to the period of under-exposure and to the period of over-exposure are of any value whatever, although they might, on the other hand, be of utility under some circumstances.

PHOTOGRAPHIC SOCIETY OF IRELAND'S EXHIBITION.

Last week the annual Exhibition in connexion with the Photographic Society of Ireland was opened in the Society's Hall, 35, Dawson-street, by the Countess Cadogan, in the presence of a large assemblage of ladies and gentlemen. The number of exhibits exceeds 500, the increase on previous years being largely due to the introduction of a new department, which embraces a splendid collection of Irish scenic views gathered together as a result of a competition held in connexion with the Exhibition under the joint auspices of the Irish Tourist Association and the Royal Dublin Society to exploit the picturesque parts of the country as a happy hunting ground for folks who indulge in holiday travel.

On entering the hall, we were struck by the fine case of photographic appliances exhibited by Messrs. Curtis Brothers, of Suffolk-street, Dublin. Their well-known Trinity hand camera is shown, together with a number of photographs taken by it, which bears testimony to the high-class results which are obtained by its use—we notice that there are some good improvements made in the '96 pattern. Another article which this firm have introduced is specially refined and washed hypo, put up in neat drums, in quantities of 1 lb.; the crystals are very small, which dissolve quickly. We noticed a number of fine results taken on the Gem plates, which prove the great rapidity of these plates. There is a very fine folding Kodak shown, of whole-plate size, also the new Kodet. Amongst other things with which we were struck is a very nicely got-up Russian iron lantern, which is a really practical instrument, having all the necessary adjustments. There were many more of this firm's specialities, too numerous to mention, all of which made a most effective display, for which they deserve great credit.

In Class I., for landscapes, Mr. George Mansfield, J.P., Morristown, Naas, a past President of the Society, has secured the silver medal for a beautiful series of river and tree scenery of refined and delicate outline, foremost amongst which is a fog study of exceptional merit. Mr. J. M. Keogh wins the bronze medal with some pretty examples of land and water effects, and a cottage scene from Lough Derg, near Killaloe. Mr. A. E. Horne, R.M., secures honourable mention for a number of river scenes from the West of Ireland. In Class II., for pictorial subjects taken with hand camera, Mr. J. M. Keogh wins first prize for some admirable snap-shots of scenery at Llanberris, North Wales. Mr. H. Goodwillie obtains second prize for yachting subjects at Kingstown, embodying some fine cloud effects. In Class III., for hand camera work on street scenes, the silver and bronze medals fall respectively to the lots of Mr. J. M. Keogh and Mr. J. Simpson, the subjects being photographed by both during a tour in Normandy, and including quaint street and seaside selections and churches, which will be inspected with interest, and Mr. Goodwillie is honourably mentioned. In Class V., for architectural and archæological subjects, the exhibits are specially attractive, and Mr. J. A. C. Ruthven, Secretary to the Society, wins the silver medal for a series of pictures depicting buildings taken in Shrewsbury during last year's Photographic Convention in that town. An impressive sample of the cunning shown by the winner in the manipulation of the camera is found in the picture of Buildwass Abbey, and other kindred landmarks of the past are no less effectively dealt with. Mr. H. Goodwillie was awarded a bronze medal for tasteful Irish views and a first-class picture of Cologne Cathedral. Mr. J. W. Kelsall obtained honourable mention for some capital reproductions of archways of the ninth-century period. Class VI. is devoted to lantern slides of landscapes, which, of course, are not "hung," but will be exhibited with limelight each evening of the Exhibition. The silver medal was won by Mr J. Simpson, and Mr. G. M. Roche was the winner of the bronze medal, Mr. J. A. C. Ruthven receiving honourable mention. In Class VII., for lantern slides other than landscapes, Mr. J. Simpson won the silver medal, and Mr. J. M. Keogh secured the bronze medal, Mr. Goodwillie receiving honourable mention. In Class VIII., for members who never before won a prize Mr. J. H. Gane won the silver medal for a dainty bit of river scenery, and honourable mention was divided between Mr. M. F. Keogh, whose Alpine scenery examples were capital, and Miss Ida Lynch, whose pictures were mostly taken in Malta, were very artistic.

In the Champion Class, which, unlike the foregoing competitions, was open to others than members of the Society, Mr. W. M. Warnerke, of Glasgow, won the silver medal with a really brilliant study of the sea at Iona, the beautiful sky conditions, the strand, and the waves being brought out with charming richness, while the picturesquely clad fisher girls, gracefully posed in the foreground, were done more than usual justice with the camera. Mr. Howard Esler obtained the bronze medal for a splendid conception of autumn. The Werner medal, for the most artistic picture on exhibition, was won by Mr. George Mansfield with an exquisite river scene. A unique feature of the display is a series of pictures by Mr. Goodwillie, representing the various periods of the spectacle of the "Buffs" parade at the military tournament last year in Ballsbridge, which, having regard to the bad light available in the interior of the building, was singularly successful. Mr. G. M. Roche has on view an interesting view of the recent shipwreck at Kingstown. In the Irish Views Department in connexion with the tourist traffic, a high standard of artistic treatment has been reached. The first prize of 5*l.* has been won by Mr. J. A. C. Ruthven for a splendid picture entitled *Evening on the Liffey*, which depicts, with great boldness and excellent perspective details, the river as seen from the Howard side of Carlisle Bridge. One of Guinness' steamers is alongside the quays, and the twilight sky is most happily portrayed. Mr. F. C. Curry, Lismore, wins the second prize of 3*l.*, his exhibit being *Ounashed Glen*, an impressive study of boulder and bush in rugged grandeur. Mr. E. E. Barrow is awarded the third prize, value 2*l.*, for a view of the *Happy*.

Family Mountains at Killarney, in which lake, mountain peaks, and sky combine to form a majestic piece of landscape work. Thirty certificates will also be awarded in this competition, which entitles the exhibitors to receive 10*s.* 6*d.* as fee for right of reproduction. Examples of colour photography are also shown, and prints depicting the results of Röntgen's new discovery of photography, which will penetrate opaque objects, also found a place in the Exhibition.

JUDGES' REPORT ON THE WATKINS DEVELOPING COMPETITION.

We have been given to understand that about one hundred entry forms were sent out to intending competitors, but the actual number competing was only seventeen. Some of these, however, sent in several sets of negatives. In many instances the conditions of the competition were not complied with.

In going over the matter again, at the request of the members of the Photographic Club, we see no reason to alter our award to Mr. B. J. Edwards, or to Mr. Ben Edwards, for the greatest difference in gradation, but we have decided to make a further award of one pound for a similar result to Mr. John Sterry.

We did not find any instance, where strongly dissimilar developers had been used, that the gradation was the same. It is worth noticing that, in most cases where strongly restrained developers had been used, half of the plate presented a much more glossy appearance. It is also worthy of note, where two halves were exposed identically, one developed with a normal developer, and the other with a developer much restrained, the latter is quite free from halation, whilst in the former the spaces are eaten up with it.

In some cases the formula given was so complicated that it required very abstruse calculations to arrive at the component qualities. In another case trade developers had been used, the constituents of which were not known to us. Although it was not permitted to use reducing agents, yet one competitor treated an exposed plate to the action of bichromate of potass, which, of course, had the effect of destroying the latent image, and so played the part of a reducing agent.

In those cases where the results were similar, the developer was not of such varying strength as to come under a widely varying developer.

We think the results of the competition open up a new field for further experiment as to the real action of a highly restrained developer.

In the case of the negatives sent us to adjudicate upon, there appears no room to doubt that the scale of gradation has been altered.

J. B. B. Wellington,
January 21, 1896. F. A. Bridge.

News and Notes.

Messrs. C. M. Higgins & Co. are putting on the market a special brush for their photographic mounter.

Mr. A. H. Bennett, of 137, Normanton Road, Derby, writes: "Please note that I have been appointed Hon. Secretary of the Derby Photographic Society in place of Mr. T. A. Scotton, resigned."

We are informed that the competition slides entered at the South London Photographic Society's Exhibition (March 2-7, 1896) will be shown by the electric lantern, the lamp for which will be provided by Mr. R. R. Beard.

The Photographic Club.—The next weekly meeting of the Club will be held in the Club-room at Anderton's Hotel, Fleet-street, E.C., at eight o'clock, on Wednesday evening, February 26. Travellers' Night. A lecture, with lantern illustrations, entitled *A Trip through Brittany*, by Mr. Henry Sturmey. Visitors will by welcomed by the members.

Royal Photographic Society.—Technical Meeting on February 25 at 12, Hanover-square at eight p.m. *The Stereoscopic Photo-chromoscope*, by Mr. F. E. Ives. *Messrs. Newton's Simple Method of Projecting Stereoscopic Pictures*, by Mr. T. E. Freshwater, F.R.M.S. *Stellar Photographs taken without a Driving Clock*, by Mr. J. Lunt, B.Sc., F.C.S.

Lantern Society (20, Hanover-square, W.).—Meetings will be held as under at eight p.m.:—February 24, *Lantern-slide Making as an Art*, by Mr. J. A. Hodges, F.R.P.S. March 9, *The New Photography*, by Mr. H. Snowden Ward, F.R.P.S. 23, *The Scottish Alps*, by Mr. Lamond Howie. Invitations to the meetings can be obtained on application to the Hon. Secretary, J. Bashall, 21, Holland-villas-road, Kensington, W.

Messrs. Smith & Brown, Photographers, &c., of Sounthorpe, write: "Our attention has been drawn to your account of introduction of the flash-light at Bournemouth last week. The experience of the South Coast Photographic Supply Association has repeated itself with us. We introduced a flashlight of considerable power into our business last week, and on Wednesday night used it for the first time; the flash so startled the people passing along the roads in the vicinity of our studio, that many rushed to the premises and endeavoured to break open the door, thinking the place was on fire, but in our case the fire brigade could not turn out, as our town does not possess one. It is needless to say it was a false alarm."

We have received the following communication from Mr. Herbert Goodchild, Solicitor, of 27, Castle Meadow, Norwich:—February 14, 1896, Mr. Robert Leamon Kidd, deceased. On behalf of Mrs. Alice Mary Kidd and myself, executors of the late Mr. Robert Leamon Kidd, I hereby give you notice that we have recently sold to Messrs. Ernest Charles Morgan and Harry Martin Dennes, of Richmond, Surrey, all the share and interest of the above-named deceased in the firm of Morgan & Kidd, of the Argentic Works, Richmond, Surrey, and that from henceforth Messrs. Morgan & Dennes are the sole proprietors of the said business, and will liquidate all liabilities.

Patent News.

The following applications for Patents were made between February 3 and February 8, 1896:—

Films.—No. 2415. "Improvements in Photographic Films to be acted on by Röntgen Rays." T. A. Garrett and W. Lucas.

Developing Trays.—No. 2494. "An Apparatus to be used in connexion with the Developing of Photographic Negatives." J. Lewis.

Focussing Scales.—No. 2554. "Improvements in Focussing Scales for Photographic Cameras." T. M. Clark.

Dark Slides.—No. 2601. "Improvements in Dark Slides for Photographic Cameras." E. Pocknell.

Cameras, &c.—No. 2607. "An Improvement in Photographic Cameras, Hand Cameras, and Changing Boxes for the same." S. P. Hyatt.

Lantern Slides.—No. 2671. "Improvements in and relating to Magic-lantern Slides." W. C. Pexton.

Colouring Photographs.—No. 2711. "Improvements in Painting and Colouring Photographs, Prints, Drawings, and the like." M. Williams.

Lanterns.—No. 2820. "Improvements in connexion with Magic Lanterns and the like." S. H. Cousins.

Dark Slides.—No. 2821. "Improvements in connexion with Photographic Dark Slides or the like." R. E. Eggleton.

Developing Plate-holder.—No. 2833. "Photographic Developing Plate-holder." W. J. Windrum.

Dark Slides.—No. 2921. "Improvements in Quadruple Photographic Plate-holders." Complete Specification. E. G. Cone and D. R. Close.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

February.	Name of Society.	Subject.
24	Croydon Camera Club	Rehearsal of Members' Slides for Exhibition on 26th.
24	Lantern Society	*Lantern-slide Making as an Art.* J. A Hodges, F.R.P.S.
24	North Middlesex	*Preparation of Collodio-chloride and Plain Salted Paper.* G. H. Moss.
24	Richmond	*Collodio-chloride Paper.* L. Taylor.
25	Birmingham Photo. Society	Open Lantern Evening.
25	Bournemouth	Lantern Night.
25	Brixton and Clapham	*Retouching, and the Improvement of Negatives.* Part I. Portraits. R. C. Whiting.
25	East London	Annual General Meeting and Election of Officers.
25	Hackney	*Lenses.* J. A. Hodges.
25	Royal Photographic Society	*The Stereoscopic Photo-chromoscope.* F. E. Ives.—*Messrs. Newton's Simple Method of Projecting Stereoscopic Pictures.* T. E. Freshwater, F.R.M.S.—*Stellar Photographs taken without a Driving Clock.* J. Lunt, B.Sc., F.C.S.
26	Borough Polytechnic	*Photo-micrography.* D. Evens.
26	Croydon Camera Club	Twenty-fourth Public Lantern Show—*A Trip to Norway.* F. A. Bridge.
26	Leytonstone	Members' Lantern Evening.
26	Newton Heath	Annual Meeting.
26	Photographic Club	*A Trip through Brittany.* Henry Sturmey.
26	Putney	*A Visit to Spain.* E. D. Purcell.—Members' Slides.
27	Ashton-under-Lyne	*Colour Lantern-slide Making.* W. Chadwick and S. A. Platt.
27	Bradford	*Wensleydale and River Yore, from Mouth to Source.* F. Brundrett.
27	Ireland	*Pictorial Dublin (Old and New).* L. H. Strangways.

28	Birkenhead Photo. Asso.	*The I. O. M.* Mr. Whetton.
28	Croydon Microscopical	Demonstration of Presto Paper. A. Roods.
28, 29	West London	Annual Exhibition of Members' Work.

ROYAL PHOTOGRAPHIC SOCIETY.

FEBRUARY 18,—Photo-mechanical Meeting,—Mr. Chapman Jones, F.I.C., F.C.S., in the chair.

Mr. W. CHESHIRE read a paper on

HAND ENGRAVING OF HALF-TONE BLOCKS,

He said that the use of the screen in half-tone work had a tendency to flatten and deaden the copy made by its means, and consequently a large and increasing amount of attention had been given to the great improvement that could sometimes be made by the engraver, and few would be found to object to this use of the engraver's art if the result showed any real advantage, but in too many instances it was difficult to detect that any improvement had been made. On the other hand, it was easy to find examples of great improvement by the judicious use of the graver in the hands of careful, skilful, and artistic men who, by vigorous touching of the foreground and careful quieting of some noisy features in the background, had done much to brighten and heighten the value of the picture. It would be well, if time and price allowed, to submit an impression of the block to the artist who produced the original, but artists were often lamentably ignorant of the requirements and possibilities of process work. The engraver should possess a natural love of art, and, if he entered into the spirit of the original, the result would be satisfactory to all concerned, and a man who combined the feeling and taste of an artist with the technical knowledge and mechanical skill of the engraver should be fairly paid for his work. The tools required for engraving on half-tone blocks were much the same as those employed in wood-engraving, and, to enable the operator to see the picture and its requirements more distinctly, the ink roller should be passed carefully over the plate, and some finely powdered chalk rubbed into the interstices. The screen used in making a block upon which hand work was to be put should have from 150 to 200 lines to the inch, for the difficulties of the toucher were accentuated if a coarse screen was used. He expressed a hope that the half-tone process might speedily be placed on a sound business basis with respect to remuneration, and to secure this there should be the most complete harmony and singleness of aim on the part of operators, etchers, and engravers, each doing his part in order to produce the most artistic and satisfactory results in the work committed to their care.

Mr. T. BOLAS said that many people, himself included, were of opinion that the very best and most artistic photographic blocks were made before the screen came into use, and, as an instance, he called attention to some prints from Pretsch blocks which appeared in the Society's *Journal* for the year 1860.

Mr. CHESHIRE did not wish to condemn the use of a screen, but thought its effects were often far too prominent.

Mr. H. W. BENNETT pointed out that the character of the lining on a half-tone was very different to that on a wood block, and a wood-engraver had to learn something entirely new when he started to work on process blocks. Much quiet and unobtrusive work could be done with multiple tools making four or five lines at a time. It was very necessary that the engraver should possess a knowledge of drawing, in order that he might insert details which were either omitted or but faintly indicated in the block.

Mr. F. E. IVES was of opinion that great improvement was effected by judicious hand work, although he had previously been much prejudiced against it. He knew that the proprietors of a well-known magazine sometimes paid for hand engraving alone on a full-page block as much as 15*l*.

Mr. W. GAMBLE had found some advantage to arise by working with an ordinary engraver's ruling machine, and thought mechanical retouching was eminently suitable to a mechanical method, such as the half-tone process.

Mr. BOLAS thought that almost ideal results had been achieved by the screen process, but could not help an old affection for the Pretsch method; there was no doubt hand engraving was absolutely necessary to produce useful blocks for newspaper illustration.

After further discussion, Mr. B. J. EDWARDS exhibited a new

CAMERA FOR THREE-COLOUR WORK,

designed to take three negatives at the same time, with similar exposure, and with one lens. The light passing the lens was received on a translucent mirror, and reflected into a chamber immediately above the main body, where the negative for the red sensation was produced on a plate protected by a suitable colour screen; a portion of the light having passed through the first mirror was reflected by a second mirror to the top of the body of the camera, producing the negative for the green sensation; and, finally, the violet negative was formed in the usual position at the back of the camera. He found the Zeiss anastigmat lens was most suitable for obtaining sharp focus and identical size in all the negatives, and thought that with some little alteration it would be possible to take snap-shots out of doors, and portraits in the studio, for three-colour work. The colour screens were made of gelatine or collodion dyed with suitable coloura.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

FEBRUARY 13,—Mr. Barker in the chair.

Messrs. E. T. Wright and G. E. Segall were proposed for membership.

Mr. T. E. Freshwater showed two more specimens of Mr. Swinton's work with the X rays, one of which was a plaice, and another a human foot, which latter had an exposure of only fifty-five seconds.

Mr. W. D. Welford showed a number of photographs of stranded whales on the New Zealand coast, and one of an ant held by finger and thumb holding a sixpenny piece, which he had calculated to be equal to a man holding ten tons.

The HON. SECRETARY, referring to the suggestion made last week that he had fogged or over-exposed certain test plates, described some experiments to prove the contrary.

ENLARGED NEGATIVES.

Mr. J. E. HODD proceeded to give his paper and demonstration on *Enlarged Negatives*. After pointing out the advisability of using a really serviceable camera for the production of the original negatives, and the evils attending the use of cheap and inferior patterns, he advised beginners in this branch not to stint their first outlay if they wish their enlarged negatives to be of any value. He proposed only to consider the making of enlarged negatives by artificial light, as being more convenient to use and leading to greater certainty of result, and described the necessary apparatus, in the present case consisting of a folding baseboard made in the form of a box to hold the entire apparatus when not in use, on the top of which were four guiding blocks to ensure the lens and light being being always at the same axis. The illumination used was obtained from a Silber paraffin burner, to which was fitted a metal hood with an oblong diaphragm parallel with the source of light, together with a crescent-shaped reflector, the idea being to cut off all extraneous light, while a certain increase of definition may be expected. A six-inch condenser was mounted on a block, keyed to the baseboard, and to the same block is also fitted a carrier for quarter-plate negatives capable of insertion either horizontally or vertically, while at the other end of the board a 10×8 camera, fitted with a rapid rectilinear lens of six-and-a-quarter-inches focus working aperture *f* 6, was fixed. Mr. Hodd then discussed the most suitable kind of negative, setting aside as useless any possessing hardness, granularity, and lacking shadow, detail, and half-tone. He preferred making a transparency by contact rather than by enlarging, and mentioned three methods—the carbon process, printing-out gelatino-chloride process, or an ordinary dry plate, the latter being the one he generally adopted. He mentioned that it was absolutely essential that the transparency should possess all the detail and half-tone in the original, and should be almost free from clear glass, transparent, and not too dense in the shadows. Some transparencies were passed round, the exposure with the majority varying from five to fifteen seconds at a distance of three feet from the lamp flame. With regard to the plate for this purpose, Messrs. Hodd had found that a good medium-speed plate answers all requirements, provided that a knowledge of its work under different conditions is possessed by the operator, and they thought that, by the use of a dry plate for the transparency, very great improvement in the result could be made. The formulæ adopted are as follows:—

Stock Solutions.

I.

Pyro	1 ounce.
Metabisulphite of potash	½ ounce.
Distilled water to	9 ounces, 1 drachm.

II.

Carbonate of potash	1 ounce.
Sodium sulphite	¾ ,,
Water to	10 ounces.

III.

Potassium bromide	1 ounce.
Water to	10 ounces.

It is recommended to take for transparencies: Pyro, 5 minims; alkali, 2 drachms; bromide, 5 minims; water to 10 ounces. For enlarged negatives: Pyro, 30 minims; alkali, 3 drachms; bromide, 10 minims; water to 1 ounce. By keeping as nearly as possible the transparencies to one standard density, it was found that an exposure of five seconds at *f*-22 was generally sufficient. Mr. Hodd also mentioned as an alternative process copying from a print direct, and some examples by this method were shown. It was recommended to give both transparency and enlarged negative full exposure, to prevent loss of half-tone, and to ensure against irregular lighting the smallest stop should be inserted when blue patches and yellow corners are plainly to be seen, but which are with a large stop not always visible. The composition of the fixing bath was as follows:—

Hypo	1 pound.
Water	40 ounces.
Metabisulphite of potash	½ ounce.

The CHAIRMAN asked whether Mr. Hodd preferred a contact or camera positive for enlarging.

Mr. HODD replied he had always used a contact transparency.

The CHAIRMAN asked why metabisulphite was added to the hypo?

Mr. HODD said it made the hypo acid and helped to clear the negative.

PHOTOGRAPHIC CLUB.

WEDNESDAY, February 12,—Mr. Haes in the chair.

On this evening the lower hall of Anderton's Hotel was used to accommodate the crowd of members and friends, the occasion being the Club's annual Ladies' Night. The entertainment, which consisted of an exhibition of lantern slides, examples of Professor Röntgen's cathodic silhouettes, and music, was under the competent direction of Mr. F. A. Bridge, and was carried through in his best style.

MANCHESTER PHOTOGRAPHIC SOCIETY.

THE Annual Exhibition of members' work was held in the rooms of the above Society on the 13th and 14th inst. The exhibits on the walls, although not as numerous as previous years, included some very fine work, chiefly brought about by the Exhibition being a competitive one. The following are the Judges' awards in the various classes:—

Class A (Landscape, 5×4 and over).—Mr. S. L. Coulthurst gained the award for *A December Sunset*, a simple but artistic study. Mr. O. H. Webb also

showed some excellent work, and Mr. T. Chilton also had a number of prints of good quality.

Class B (Landscape, 5×4 and under).—Mr. S. L. Coulthurst was also the winner in this class for a frame of four quarter-plate pictures.

Class C (Interiors).—Mr. J. Wood, with a set of Chatsworth pictures, was awarded the prize, the technique being very fine. Mr. J. Wolfendon also showing good work of Lincoln and Hereford Cathedral.

Class D (Instantaneous).—A series of snap-shots of street life by Mr. Coulthurst was first; and of a different character were a frame of five sunsets, which were of an artistic nature, the work of Mr. A. E. Casson.

Class E (Enlargements).—There was a good entry for this class, the prize going to Mr. F. Edwards for a 15×12 bromide from a quarter-plate of *A Street in Lisieux;* others of excellence were *Arthog Lake*, Mr. F. Andrews, and *Ludlow*, Mr. J. W. Young.

Class F (Lantern Slides).—This class brought a large number of entries, a set of six various slides by Mr. Harry Wade gaining the award; other slides, showing technical and artistic excellence, were sent in by Mr. H. M. Whitefield, Mr. S. L. Coulthurst, Mr. J. Wood, Mr. W. G. Coote, and Mr. H. V. Lawes.

Class G (Stereoscopic Slides).—Mr. J. Wood, for a set of six transparencies.

Class H (*Genre*).—No award.

Class I (Home Portraiture).—Mr. J. W. Young, for a good picture of *Laughing Eyes*, a brown toned study of a girl.

Apart from the competitions, there were a number of non-competitive photographs, amongst others being *Yacht Murre*, an enlargement from a quarter-plate snap-shot, by Mr. J. Brier. Enlargement of *Leukerbad*, Mr. J. G. Chapman; a 12×10 direct head; red carbon by Mr. H. Wade; and a number of half-plate instantaneous shots at Blackpool, by Mr. W. Tomlinson.

Lantern exhibitions were given each evening. On Thursday the 13th by Mr. Harry Wade, entitled *Glimpses and Glances*, and embracing views of the Isle of Man, Cork, and the Blackwater, English Lakes, and Shakespere's country. On Friday evening by Mr. S. L. Coulthurst, entitled *Street Life in Manchester*, the audience in imagination walking through the principal streets and into the lowest slums.

After each exhibition there were shown on the screen the slides sent in for competition, and also non-competitive slides sent in for selection by the members, including Messrs. J. Brier, E. Woodward, F. W. Andrews, J. Whittaker, and A. E. Casson. Messrs. W. Artinstall, J. W. Wade, and Geo. Wheeler were the Judges in the competitions.

Brixton and Clapham Camera Club.—February 11, Mr. J. W. Coade (President) in the chair.—Mr. R. G. F. KIDSON related his experiences of

THE TROUBLES OF A TOURIST.

Mr. Kidson gave an interesting and humorous narrative of the difficulties encountered on a tour with the camera, giving many useful hints as to carriage of luggage, changing plates, packing the exposed plates, &c. A general discussion, occupying one and a half hours, followed, many members speaking of incidents in tours which they had undertaken, and of failures through defects in the apparatus being found out too late, perhaps only on development of the plates exposed, and of other things connected with photographic touring. Mr. Kidson received the unanimous thanks of the meeting for bringing forward a subject of such practical importance, with the probable result of lessening the future troubles of tourists belonging to the Brixton and Clapham Camera Club.

Croydon Camera Club.—A very crowded gathering of members ensued on Wednesday, the 12th inst., no doubt greatly attracted by the opportunity afforded them of inspecting a splendid "one-man" collection, consisting of forty of the choicest medalled and other works of Mr. Ralph W. Robinson, of Redhill. The above comprehensive exposition of photographic possibilities as regards portraiture, *genre*, and landscape, formed a delightful series of object-lessons, which were studied and greatly admired by the critical audience. Hopes were freely expressed that so valuable and artistically praiseworthy a series might in the near future be displayed at some hall in Croydon, where the general public might be able to inspect them. The annual report, which the President read to the members, indicates that the Club is in a wonderfully flourishing condition. The meetings have been numerous and the attendances large. Twenty-two members were elected during the past year. The Club has been able to repay the President a loan made during the first year of its existence, and starts the new year entirely free of every penny of debt, and with 4*l.* cash balance remaining over from the last year's receipts. On the proposition of Mr. J. Smith, Mr. Hector Maclenn, F.G.S., F.R.P.S., was for the seventh year in succession elected President. The following Vice-Presidents were appointed:—Mr. James Glaisher, F.R.S., the Mayor of Croydon (Alderman F. T. Edridge), and the Right Hon. G. T. Ritchie, M.P. There was a sharp competition for seats on the Council, the balloting resulting as follows:—Messrs. Burn, Hirst, Isaac, G. W. Jenkins, A. Jenkins, Noaks, J. Packham, Rogers, J. Smith, S. H. Wratten, Wreford, and Watson, who were declared elected. Mr. H. E. Holland was, amidst great applause, re-elected Hon. Secretary, Mr. Brown being appointed Hon. Assistant Secretary. The following candidates were elected members of the Club:—Messrs. Ibeson, P. Wratten, F. J. Elkin, and A. Underhill. A vote of thanks was accorded to Mr. Ralph W. Robinson for contributing the fine selection of his photographs already alluded to. The annual dinner was fixed for Wednesday, March 11, the following being appointed stewards:—Messrs. Frost, Waller, Wreford, and Hirst. Mr. J. T. Sandell presented the Club with an exceptionally fine pair of prints, measuring fifteen inches by twelve inches, taken in connexion with the Club excursion to visit the s.s. *Ormuz*. The President handed round several freshly made shadowgraphs, produced with the Röntgen rays by Mr. Swinton. Messrs. A. J. Noaks, Rogers, J. Noaks, A. Jenkins, and J. Smith exhibited a variety of flashlight pictures, which were of high technical quality, and some of which were of considerable artistic merit.

Hackney Photographic Society.—February 11, Mr. William Rawlings presiding.—Work was shown by Messrs. Roofe and Hensler. Mr. J. CARPENTER showed prints on

VENUS PAPER,

which were much admired. In reply to questions he gave the following information concerning the printing-out paper. It was a paper of recent introduction, and, to his mind, fully bore out the description given by the makers. It was issued in three grades—rough, medium, and smooth. He had tested all, and was much pleased with the results. For small pictures the medium paper was, perhaps, the best, as the surface was not too pronounced in roughness, the manipulation simple, and toning rapid, directions being as follows:—Print somewhat deeply and wash for a few minutes, place in a solution of salt (two and a half per cent.) for five minutes, afterwards well wash, and then place in toning bath. This might be any formula for gold toning, but the speaker had found the platinum bath as follows to give the finest brown tones:—Potass. chloroplatinite, 1 grain; chrome alum, 50 grains; salt, 10 grains; water (distilled), 10 ounces. When freshly made, this bath tones rapidly. The print should be removed when of a warm brown colour, and toning arrested by immersion in a ten per cent. salt bath. After well washing it should be fixed in a solution of hypo, one ounce to ten ounces of water, for twenty minutes, and afterwards washed for two hours in running water. Warm water might be used to quicken the washing.

Woodford Photographic Society.—February 6, Mr. E. B. Caird in the chair.—A few

PHOTO-MICROGRAPHS

were shown by the Secretary, and, as these were among the first taken by any member of the Society, they caused considerable interest. Mr. EMLER explained his method of working, which is simplicity itself. The microscope is so adjusted that the eyepiece end is inserted into the front of the camera. The lens having been removed, all extraneous light is carefully excluded. The object is then placed on the stage of the microscope, a two-inch condenser behind that, while a duplex oil lamp was used for illumination. The exposure varied with the objective used, and ranged between thirty and ninety seconds. Ilford isochromatic plates and pyro-soda developer were used. Mr. WARNERKE's paper on *Development of Printing-out Papers* was then read. The substance of the paper was that, after a short exposure to either daylight or artificial light, the paper can be developed and then toned, the results being equal, if not better, than direct printing and toning, formula and the whole method of treatment being very fully explained.

Woolwich Photographic Society.—February 14, Mr. W. H. Dawson presiding.—An interesting communication was made to the Society by four of its members, viz., Messrs. W. H. Dawson, J. B. Panting, J. Quick, and F. W. Machen, who stated that when the remarkable discoveries of Professor Röntgen were first made known they procured a Crookes' tube with a view of demonstrating these experiments in the so-called

NEW PHOTOGRAPHY

for themselves. They had been so far successful that they produced for the members' view some excellent prints from their first negative by this new process. They also explained that the powerful currents ordinarily used were not altogether necessary, as they had arrived at these results with ordinary science-class apparatus. They were able to prove that coal is transparent or nearly so, and glass quite opaque, the latter being a point upon which various opinions had been expressed in the daily press. These gentlemen intend continuing their experiments with the idea of showing the results at the forthcoming Exhibition on Thursday next, the 27th inst., and the two following days. They also intend to show the process in actual operation on those days, as they have no doubt it will be of great interest to the general public. Mr. H. J. DALBY, another member of the Society, then read a paper on *Toning and Finishing*, dealing with most of the printing processes. His paper raised many points for questions and discussion, which were kept up for a considerable time.

Birmingham Photographic Society.—February 11, Mr. G. F. Lyndon in the chair.—Dr. HALL EDWARDS, who has been so successful during the past week in obtaining

NEGATIVES BY RÖNTGEN'S METHOD

with X rays, gave many interesting results of recent experiments, and demonstrated his method of working before a large audience of members and friends. The lecturer said, owing to a number of circumstances, he had been lucky enough to obtain the first photograph in this city. For that achievement he had to thank to a great extent Mr. Boothroyd, who placed at his disposal one of the finest coils out of London, and Messrs. Philip Harris & Co. for the expedition with which they provided him with a Crookes' tube. The nature of the Röntgen's radiations having been explained by the aid of a partial vacuum tube.) Mr. Hall Edwards drew particular attention to Dr. Röntgen's accidental discovery that certain rays coming from the radiant matter would penetrate substances considered hitherto as opaque. In photographs which he (Mr. Hall Edwards) had taken the rays had not penetrated some of the metals, although they had others, but he believed with sufficient length of exposure they would be to take a photograph through an eighty-one ton gun. He expressed a hope that the rays would for the future be called Röntgen's radiations, rather than the "New Light," which was an absurdity, because they were not lights, being absolutely invisible to the eye. The exact method by which the rays penetrate various metals and opaque substances remained to be discovered, but they evidently found their way between the molecules and atoms and went completely through. Of course, some substances are more opaque to them than others, hence they were able to photograph the human hand; but, curiously enough, most of the substances which were perfectly transparent to ordinary rays of light were opaque to these rays. For instance, glass was opaque to an extent, and if it contained an amount of lead it was exceedingly opaque, and the same was the case with crystals, while the rays passed through an inch of aluminium with the greatest ease. Having technically explained the electrical apparatus used by him in the experiments,

the lecturer showed several interesting results by means of lantern slides. In one of these a coil of wire wound round the forefinger, was seen right through the bone. To ascertain the action of the rays upon bone, the lecturer first experimented with a piece of bone absolutely devoid of animal matter, and then with a piece of decalcified bone, the result going to prove that it is the chalky matters that caused obstruction. In his own mind he had no doubt that he could detect a needle in a hand in a very few minutes, and point out the exact position of it. As to the future of this photography it was impossible for him at this early date to say very much, but he thought it would be of very great practical use, and he trusted that he should again have an opportunity of coming before the Society and explaining his future researches more comprehensively.

Leeds Camera Club.—February 13.—Continuing his series of lectures on *The Chemistry of Photography*, Dr. Thresh explained fully the nature, preparation, and use of

PRINTING PAPERS

before this Club. After dealing in a most exhaustive manner with the theoretical side of the subject, the learned President gave his hearers a few useful working formulæ, amongst others may be mentioned the following:—*Plain or Matt-surface Paper:* Immerse in sizing and salting solution of arrowroot, ¼ ounce; water, 32 ounces; chloride of ammonium, 1½ drachm. Sensitise upon a 45 grain silver bath, acidified with citric or acetic acid. Another, in which gelatine is the sizing agent, is gelatine, 120 grains; water, 5 ounces; to which add 90 grains of chloride of ammonium. Float on silver bath, as in last formula. In preparing *Albumenised Paper* the white of one egg is required to 16 ounces of water, to which 160 grains of chloride of ammonium are added; but in this case a silver bath of 50 grains to the ounce is required, and must be alkaline, and not acid, as in the previous methods. In the preparation of fabrics for photographic printing a similar sensitising bath is used, but a substratum of gelatine, rendered insoluble with chrome alum, must be previously made and applied. The advantages derived, and the chemical changes that take place by "fuming" the paper before printing were also a subject that received considerable attention. The more recent processes of gelatino-chloride and collodio-chloride were most explicitly described, and the various methods of the development of the partially printed image were fully discussed, the lecturer recommending 4 grains of pyro, 3 grains of gallic acid, and 1 grain of citric acid as the best formula for most chemical papers. As regards toning, Dr. Thresh discounted the alleged "permanence" of the gold-substituted image, and strongly advocated sulphur toning alone. For this he claims absolute permanency, and declares that a print toned with sulphur can never fail, his practice being to fix thoroughly *first*, and tone afterwards. An animated discussion followed the conclusion of the lecturer's remarks, which, if correct, has sealed the doom of the utility of gold chloride in photography.

Newcastle-on-Tyne and Northern Counties' Photographic Association.—February 11, Mr. J. P. Gibson (President) in the chair.—Mr. J. E. Goold read an exhaustive paper on the collotype process, illustrated by exhibitions of plates, apparatus, and finished prints. Afterwards Mr. Goold showed numerous successful results of his experiments in photography by means of

THE RÖNTGEN OR X RAYS.

Working with a Wimshurst machine and a Crookes' tube of very small dimensions (one inch) had yielded results quite equal to most of the exhibited specimens; but his apparatus necessitated an exposure of thirty minutes. The most noteworthy specimen was a photograph of a plate of aluminium, which was enclosed in a cardboard box. The aluminium plate had on its surface printed matter in a coloured ink, evidently composed of a metallic salt, with the result that the printing, being of greater opacity to the X rays than the aluminium, was clearly shown in the photograph. Mr. Arthur Lander also showed several very good examples obtained by a tube of the same kind as that used by Mr. Goold, but working in a quite different direction. He used the 100-volt alternating current from the main, reduced to ten volts by a transformer, thence into an induction coil giving a 4-5 inch spark. One end of the secondary coil was then connected to one of the terminals of the Crookes' tube, and the other end connected to the inside of a Leyden jar, the inside of the jar being then connected by means of a spark gap to the other terminal of the Crookes' tube. Mr. Lander showed a photograph of a wire taken through prisms of wood, ebonite, and pitch, which resulted in an unbroken straight line, thus proving that the rays were not refracted, and that they were not Hertzian rays, as these latter are refracted by a pitch prism.

Oldham Photographic Society.—February 13.—Mr. N. Luboshez, of the Eastman Photographic Materials Company, London, attended a meeting of this Society at the Lyceum, when a very pleasant, interesting, and instructive time was spent. The meeting took the form of a *conversazione*, and Mr. Luboshez gave the members valuable information on many matters photographical. Enlarging, printing, and developing were all touched upon. Why failures frequently occur, and how success may be attained in the making of negatives, prints, and transparencies, were graphically explained and plainly demonstrated by Mr. Luboshez, who is evidently a great master of the art, and he fairly succeeded in gaining the attention of his audience, who showed their appreciation by asking a great number of questions and by passing a hearty vote of thanks at the close of the meeting to him for the advice and explanations he had given, and to the Eastman Company for their kindness in allowing their representative to spend an evening with the Society.

1896. FORTHCOMING EXHIBITIONS.

February 27-29 ..... Woolwich Photographic Society.

ORTHOCHROMATIC PHOTOGRAPHY WITH ORDINARY PLATES.

To the EDITORS.

GENTLEMEN,—I hope you will pardon me for bringing up, at this late date, the subject in dispute between Mr. Ives and myself, but I have been so pressed by my regular work that I was unable to make the experiments necessary to form the basis of a reply to Mr. Ives.

Mr. Ives stated that the Seed is not the only ordinary plate which has orthochromatic properties; and, as this is a matter in which he could not possibly be mistaken, I accept his statement.

Not content with knocking out what I intended to be the only point in my letter, he goes still further, and attacks *the dye* (?) I used, and in this attack he displays a spirit I least expected from one who has shown such an ability in scientific investigation as he has.

In the following I hope to prove that his attack (see his letter, page 813, December, 1895) was altogether unwarranted, and that, even if his conclusions should chance to be right, they are based on a knowledge of chemistry of whose soundness I will allow the reader to judge. Mr. Ives stated that he had made tests of the dye aurine, which Dr. Vogel and I had recommended, and then proceeds to dilate upon its worthlessness for screen purposes. To be brief, I never recommended the dye aurine, nor have I any knowledge of Dr. Vogel having recommended it. In *Die Photographie farbiger Gegenstände* (Dr. H. W. Vogel, Berlin, 1885), and in the *Taschenbuch der Photographie* (Dr. E. Vogel, Berlin, 1892), the dye "aurantia" is recommended, and *this* is the dye that I mentioned in my letter (page 735, November, 1895).

According to *Richter's Organic Chemistry*, translated by Smith, aurin (or yellow corallin, $C_{19}H_{14}O_3$) is the carbinol anhydride of trioxy-triphenyl methane, while aurantia is the ammonium salt of hexanitro-diphenyl-aurine ($C_{12}H_5N_7O_{12}$). Dr. Vogel, in *Practische Spectralanalyse* (Berlin, 1889), also says that aurantia has no characteristic spectrum reaction, but gives one for aurin. Well, so much for that; now for the results of the experiments.

The following experiments, of which I enclose proofs to the Editors were all made on Seed's ordinary 26 × plate.

First Formula.

Aurantia	·3	gramme.
Warm alcohol	25	c. c.
Collodion (two per cent.)	75	c. c.

Second Formula.

Chrysoidine	·5	gramme.
Alcohol	50	c. c.
Ether	50	c. c.
Pyroxiline	2	grammes.

Third Formula.

Naphthol yellow	·5	grammes.
Water	200	c. c.
Hard gelatine	10	grammes.

I tried one gramme of naphthol yellow to this amount of solution, but it crystallised out on drying. I coated thin mirror plate glass twice with the first formula, but only once with the others. The exposures were all made under a skylight, the subject being the colour plate which accompanies Vogel's *Handbuch der Photographie*, but were not all made on the same day. The stops used were *f*-25, *f*-8, *f*-12, according to judgment.

No. 1.	Without	screen.		
„ 6.	Aurantia	„	(single)	
„ 7.	Chrysoidine	„	(„)	(very dark to focus).
„ 8.	Naphthol yellow	„	(„)	(easy to focus).
„ 9.	„	„	(double)	screens face to face.
„ 11.	„	„ + chrysoidine	(hard to focus)	„ 7–8 „ „
„ 12.	„	„ + aurantia	(lighter than 11)	„ 6–8 „ „
„ 13.	Aurantia		(double)	two screens like 6.
„ 14.	Chrysoidine		(„)	„ „ 7.

The reader having a copy of Dr. Vogel's book containing this colour plate can follow my explanation best.

No. 1. Without a screen shows the yellows and greens too dark, while the ultramarine blue is nearly as light as the pink.

No. 6. Aurantia single shows the yellows lighter, and the blues darker, than in No. 1.

No. 7. Chrysoidine single shows no improvement over No. 1, and makes the pink lighter than the white paper on which it is pasted.

No. 8. Naphthol yellow single is a decided improvement, the yellows and greens being lighter, and the blues darker, than in No. 1, but the difference is not great enough to show the relative brightness.

No. 9. Naphthol yellow double is but a slight improvement on No. 8, showing that the naphthol yellow had about reached its maximum effect.

No. 11. Naphthol yellow plus chrysoidine. This combination yields, as stated by Mr. Ives, almost perfect results, the ultramarine and dark

green being perhaps a little too dark in comparison with the Prussian blue.

No. 12. Naphthol yellow plus aurantia gives fair results, but would have been better had the aurantia screen been darker, so as to have given the blues darker in comparison with the red.

No. 13. Aurantia *double*. This, to my "colour-blind eye," gives results differing in such a slight degree from No. 11 that it is hard to say which is the better, and it would have been still better had more of the dye been used. It was not near as dark as No. 11. When compared with aurantia *single*, goes to proves Mr. Ives's statement "that little may depend on the kind of dye used, and much on quantity."

Upon the results of this experiment I base the statement that aurantia is, when used at proper strength, a dye suitable for screens for orthochromatic photography. This, you will notice, is an issue which I had no idea of making when I wrote my first letter.

No. 14. Chrysoidine double. This screen was so dark that I focussed with difficulty, although I used the full opening of the lens and on a bright day. The results are worse than without a screen, but whether it is better than aurin, as Mr. Ives states in his reply to Dr. Eder, I am unable to say, as I have never used the latter dye.

In conclusion, Mr. Editor, I would say that, if you find from an inspection of the prints sent herewith that I am wrong in my judgment, you will kindly say so, as I have no desire to wrong Mr. Ives. I would also suggest that, should there be any further controversy, it be carried on in a more friendly spirit than in the past.

As for Mr. Burton's letter (page 15, January 3), if he has only flattery for Mr. Ives and mean insinuations against me to contribute, I would advise him to take Paul's advice to women in church.

Having accepted Mr. Ives's statement that he had used other makes of ordinary dry plates with orthochromatic results nearly equal to those which he obtained on Seed's, I cheerfully accord to him the honour of being the first, to my knowledge, to show the value of an ordinary plate for that purpose. The aurantia I used was purchased of A. Moll, Vienna, Austria.—I am, yours, &c., MILTON B. PUNNETT.

Jennings, Mo., U.S.A.

PHOTO-CHROMOSCOPES.

To the EDITORS.

GENTLEMEN,—In his letter in your last issue, Mr. Ives raises certain questions which, I think, call for some notice from me.

In the first place, Mr. Ives, although expressing his belief in the independence of my invention, remarks that his patent, *disclosing everything*, was published in America two months before I applied for provisional protection. As a matter of fact, until little more than a month ago I was perfectly ignorant of the existence of this patent; and, so far from disclosing any information to me, it could not have done so, since, *fully six months before I applied for provisional protection*, I had tried the methods specified in it, and found them unsuitable for my purpose.

In my last letter I asserted that the "step" idea was the first point I hit upon. This was in the beginning of 1894, and surely Mr. Ives does not claim to have published it then! In fact, I am of opinion that he would find it a most difficult task to prove the "step" arrangement to be his invention, or that of any single indivsdual, or even that he was the first to disclose it.

As I stated in my last, coloured-glass reflectors may be good enough for a viewing instrument, but I repeat that, for a colour camera, they are well-nigh useless. Mr. Ives makes a great mistake in supposing that my silvered mirrors are so exceedingly delicate. So far from their being so, they may be cleaned and well rubbed with a soft cloth, and are as little liable to damage as coloured glasses. When I showed Mr. Ives my apparatus, I distinctly understood him to say that he had not tried silvered glass mirrors, as he did not think it possible to obtain the deposit sufficiently thin.

In his last paragraph Mr. Ives maintains that it is evident that my invention is constructed in accordance with his patent, for the purposes specified therein, and infringes his patent claims.

To all this I reply, that he must know such statements to be incorrect. Instead of my instrument being constructed from his specification, it is decidedly superior to his for the purpose for which I designed it.

As for my purpose being the same as his, I need only repeat what I said in my last letter, that my aim has been to produce not only a viewing apparatus, but a camera in which the three negatives may be taken in the shortest time. The whole design of the instrument, and the difficulties I had to overcome, were connected solely with this aim, and let me assure Mr. Ives that, had I been content with the results I got from coloured glasses, my apparatus would have been patented *before* his photo-chromoscope.

Then, as to the infringement of his patent claims, I would ask Mr. Ives to read my claims when published before coming to such a conclusion, and, when he compares his patent with mine, he will probably find that not one of the claims I make is identical with his.

Finally, I may be pardoned in saying that the few results I have had time to obtain in my apparatus appear to me quite as good as any Mr. Ives has shown hitherto.

No one would gainsay the good and sound work Mr. Ives has accomplished in the three-colour process, nor the skill and ingenuity displayed in his contrivances; but surely he has exceeded the bounds of reason in taking up the attitude he does in the last paragraph of his letter.

No single individual is entitled to pose as the *fons et origo* of human intelligence, attacking a scientific problem such as three-colour photography, nor is any one justified in claiming the independent labours of others in solving such a problem.—I am, yours, &c., B. J. EDWARDS.

The Grove, Hackney.

To the EDITORS.

GENTLEMEN,—The more than vigorous attack upon me made by Mr. Ives compels me to ask you to publish this brief reply. On March 29, 1894 I took out a patent for a chromoscope. In the specification of this patent [I claimed "to make this instrument by superposition of two platinised mirrors, one in front of the other." I did this, and on June 7, 1895, I took out an *additional certificate*, giving three different drawings, showing three ways of placing the platinised mirrors, one in front of the other, in accordance with my claim in March 1894.

Mr. Ives makes use of an analogous arrangement, but with coloured glasses. This arrangement has also been adopted by others in Germany, as well as by Mr. Edwards, as published in the last number of your JOURNAL. Mr. Ives therefore claims too much. Even the date of his patent proves that he had not the idea before me. Further, by what right does he forbid me the sale in France of an instrument which I have patented, and for which he has no warrant, by application for a patent? I reassert it; facts are stronger than words, however vigorous the latter may be. I have but to adhere strictly to my right, and to follow the road Mr. Ives points out, but with more serious intent, and forbid him the sale in France of a chromoscope, where mine has been duly patented at a sufficiently early date, and where he has not any patent. He has therefore no standing, either in fact or in law.—I am, yours, &c., C. NACHET, *Optician.*

11, *Rue de la Paix, Paris, February* 11, 1896.

"USE OF THE SWING BACK."

To the EDITORS.

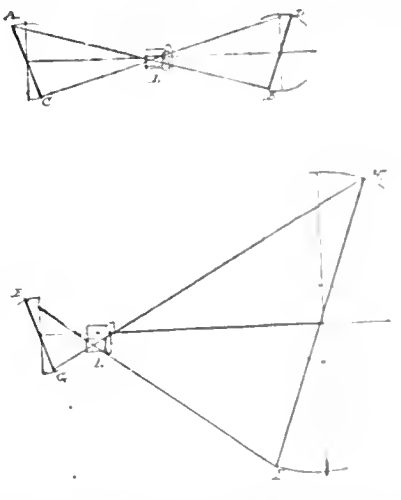
GENTLEMEN,—I read the reply of the writer of this article, as inserted in your number of the 17th instant, and I am much obliged for the explanation.

When it is said that the process of combined and adequate inclinations of negative and sensitive tissue for positive, as described in my article in the *Bulletin Belge*, does not present any novelty to ordinary photographers, I beg to differ, and so do the numerous Continental photographers that reproduced the process as a novelty.

I should feel obliged if your correspondent would kindly name *one* of the numerous photographic treatises, publications, periodicals, or papers read, that described this process previous to the date of my publication.

I wish also to state that this mode of redressing the lines can hardly be applied to enlargments on account of the want of sharpness. When enlarging, the whole of the field cannot be got into equal focus.

When negative and positive to be produced are of equal sizes and swing from the perpendicular a same number of degrees, the rays are of



equal length—A B is as long as C D. When a small negative is placed in a similar position to produce an enlargement, say, of four diameters, the rays or lines are unequally long—E F is much shorter than O H. The consequence is that the enlarged image is vastly out of focus.—I am, yours, &c., VICTOR SELB.

45, *Avenue Moretus, Anvers, January* 26, 1896.

COLOUR-RENDERING ON ORDINARY PLATES.

To the EDITORS.

GENTLEMEN,—May I, *pro tem.*, make reply to the letter of Mr. E. J. Wall, published in your last, respecting Mr. White's lecture at the Croydon Camera Club?

Mr. Wall's letter was only to hand at the Club on the 12th inst., and, Mr. White being absent for several weeks, it will, I fear, be yet some time before he could accept Mr. Wall's challenge to fight the matter out before some "independent and competent body." If by "independent" Mr. Wall means unbiassed, I fancy he will be unable to find such, for, unfortunately, in the upper circles of photographic societies there exists a most perverse objection to giving ear to the conclusions of practical workers.

Inasmuch as Mr. White has lately spent many months in copying coloured paintings, and has tested a variety of plates, screens, lights, &c., in order to get what he aimed at, I expect that he would carry small weight with any jury of theoretical experts, and none other seems likely to be available.

It has been one of the most notable curses of photographic advancement that for years the road has been barricaded by the *débris* of laboratory twaddle and the rubbish of text-books; for the foregoing, and other reasons, I should, if asked, advise Mr. White to leave the challenge severely alone, remaining content to let the photographic world take his conclusions and opinions as they stand for just what they are considered worth, remembering, however, that they are the outcome of personal experience, gained in reproducing several hundred works of art to the satisfaction of an employer who was keenly sensitive to the proper translation of colour values into the tones of monochrome.

Should Mr. White decide not to meet Mr. Wall in friendly contention, I will try and arrange for the publication, in one of the technical journals, of a paper, setting forth, with more precision and fulness than possible in a mere abstract, how Mr. White seeks to substantiate his case.—I am, yours, &c., HECTOR MACLEAN.

Croydon, February 14, 1896.

PHOTOGRAPHIC COPYRIGHT.

To the EDITORS.

GENTLEMEN,—Perhaps a few facts, or what we believe to be facts, concerning fees for the reproduction of photographs, might help to show that the minimum charge of the Photographic' Copyright Union is impracticable, at present at least.

Just the other day a representative of the *Border Magazine* called on us about photographs for reproduction, and our price for each view. He told us that Messrs. Wilson & Co. were charging 10*s.* 6*d.* for each photograph reproduced; but, as that price was too high, they were getting views from Messrs. Valentine & Son to reproduce for 5*s.* each. Our price being higher than Valentine's, he said it was no use looking at our work, and he didn't!

Now, as we do a good deal with London publishers, both in views and portrait studies, we have some experience of what we are writing about, and the rule may be laid down, that no hard-and-fast line can meet business requirements. The publisher knows, as well as the photographer, the value of most subjects submitted to him, and accordingly we find our prices vary on occasions, and properly too; no publisher needing such subjects will demur to a reasonable price.

It is different with popular views of places that sell generally, and Valentine's price for these, although a little lower than our own, is practicable. We could adduce many reasons for this statement. For instance, we supplied above a score of views to *St. Paul's Magazine*, London, at a price a little higher than that reputed to be Valentine's, and very soon after the arrangement had been completed another Edinburgh photographer offered his work at about half our prices. Of course we put little stress on this fact, knowing well that high-class publishers and block-makers have a keen eye on the work that suits their particular requirements. We may not refuse our sympathy to the weaker members of our craft when they endeavour to get a half-loaf rather than no bread; but it is not in human nature to quietly look on when one sees the so-called amateur lending himself to the "cheap-jack" publisher and printer, and this same amateur not seldom receiving his salary from the purses of the ratepayers. Many of these fellows have four and six weeks of summer holidays, besides every Saturday, or a large part of that day, in which they can devote themselves to photographing popular subjects, and suchlike. Not a few are excellently equipped in lenses, &c. and can really photograph well.

Now, the photographic profession cannot altogether ignore these photo-parasites. Their work has to be reckoned with now and then; and that, along with the other finger-posts we have pointed out by the way, demand more flexibility in Rule XXIII. of the Photographic' Copyright Union. We have no doubt, the rule has already done good, but we question if its retention longer be beneficial to any one.

Whether or not, photographers should all be sincerely thankful to the Copyright Union. Already its moral influence is great. Its very name is a terror to piratical printers and advertising schemers, ay, and some others we could name.—I am, yours, &c., JOHN PATRICK & SONS.

52, Comiston-road, Edinburgh.

A WARNING TO ASSISTANTS.

To the EDITORS.

GENTLEMEN,—The letters which have appeared in the JOURNAL from time to time exposing the sweating and bullying which is carried on by a firm with a large cheap trade were hailed with acclamation by the assistants employed by the firm. Although the name was not published, the firm was at once recognised, and many were the expressions of thanks to the JOURNAL for bringing the matter before the photographic world. Some little time since, through force of circumstances, I was employed by this cheap firm of photographers. After being bullied day by day for a few months, I at last could endure it no longer; so intolerable had it become that I resolved to give notice, which was received with a look of wonder by the head of the firm. After leaving, I made many applications for employment to London photographers, and in each case I was received with courtesy, but was informed they did not care to "employ any hands from a cheap house." I was completely annihilated with surprise. I walked home only to find that the country firms whose advertisements I had answered had not replied to my letters, so I presume they also have no wish to employ "hands from a cheap house."

This is a great injustice. I maintain that an assistant may in every way be qualified to turn out good work though he may have been employed for a few months by a cheap firm. It is, indeed, very hard to be boycotted for the simple reason that assistants have, through circumstances over which they have no control, served with a third-rate firm.

I can now see the force of the remarks made by the head of the cheap firm, *i.e.*, that his operators and assistants always stop with him for years." Yes, for they find a great difficulty in obtaining another engagement after being in his employment. Other firms, during my walk in search for employment, remarked, "Your late firm wish to have the monopoly." There is some truth in this; they have now several branches in London, to which I have no doubt they will add. This well-known fact may aptly serve to exemplify the high pressure at which competition, in respect to the cheap work, has been carried on of late years by this firm. I have seen assistants bullied before sitters for taking 10*l.* on a Monday and not "keeping it up" throughout the week. It matters not how dense the fog, or how wet or dull the day, those in charge of studios are expected, under threat of dismissal, to do a "good business," and at the present time, with the trade in such a depressed condition, the assistant must come in for any amount of bullying. This system of bullying is carried on by the heads of the firm, and is eminently calculated to make the most cheerful assistant's life a burden to him. There can be no wonder that the assistants are not treated as human beings, but as machines for turning over money. There can be no possible excuse for this absolute want of justice and humanity.

This letter would be incomplete without I mention the principal grievances. They are as follows:—Bad pay, long hours, stoppage of pay for illness, no holidays in place of Good Friday and the four Bank Holidays, Friday's developing to be done on Saturday (which would enable all hands to leave at five p.m. on Friday); last, but not least, the bullying, which is carried on at all the studios. In fact, gentlemen, the assistants are treated as mere serfs, who have no rights. At the works of this firm great discontent prevails with regard to the treatment of the printer and toner, &c., who have a formidable array of grievances; would space permit, I could fill pages of the petty tyranny of this firm.

In conclusion, I should add that at the time of my leaving there was some talk of a meeting of the assistants after business hours to consider what course to take with regard to their treatment. Whether the meeting was held, I am unable to say; but, if not, it will only be a matter of time, for the hour will come when all the grievances will be perfected, but will never be if the assistants sit down and content themselves with writing grumbling letters, instead of actively engaging in rectifying all defects which abound in this firm. It is pitiful that a large firm, instead of conciliating their workpeople and treating them, as they can well afford to do, should treat them like hucksters. Still the assistants find some comfort in the thought that they can rely upon the courtesy and kindness of the Editor of the JOURNAL to assist them in the redressing of their proved grievances. But I hope that the heads of this firm will have learnt enough from the recent letters, published in the JOURNAL, to perceive that the true interests of their pockets lie in the better treatment of their assistants. Apologising for the length of this letter, I remain, yours, &c., A VICTIM.

London, February 15, 1896.

THE BEAUFORT LIGHT.

To the EDITORS.

GENTLEMEN,—The light used for the gaslight demonstrations taken notice of in your issue of the 14th inst. was the Beaufort gaslight for portraiture.

As the name was omitted from your notice, oblige by publishing this.—I am, yours, &c.,

W. A. VÉREL, JUN. (Albion Albumenising Company).

96, *Bath-street, Glasgow, February* 17, 1896.

PHOTOGRAPHY AT THE ROYAL INSTITUTION.

To the EDITORS.

GENTLEMEN,—About the 3rd of January last I received, whilst at Montreux, Switzerland, the following note:—

"*Albemarle-street, January* 1, 1896.

"DEAR SIR,—I should be very glad if you would show your panoramic camera again at the Royal Institution *conversazione*, on January 31, also your fine collection of photographs taken during the past three years.—Truly yours, HERBERT FYFE, *Royal Institution*."

To this I replied that the photographs were at the Polytechnic Institution, Regent-street, and that I would be very pleased if they could arrange for their exhibition; as regards the instrument, that a new one was being made for me in Geneva, and that, if ready in time, I would show it. To this letter I had no reply. So, on January 25, I wrote, saying that the instrument was completed, and, if the Royal Institution proposed to exhibit my photographs, I would attend personally and show the instrument; in conclusion, I added: "Wire reply, 'Yes,' or 'No.' To this I had a wire, "Yes." Accordingly, I left Montreux on January 28, arriving in London on January 29. I again wrote to Mr. Fyfe, asking at what hour I should attend with instrument, and had for reply, 7.45 p.m. at latest. At that hour I presented myself at Albemarle-street, and asked for Mr. Fyfe. I was told he had not come. I asked another gentlemna, who was acting for Mr. Fyfe, where the instrument should be set up. He indicated a corner. I then looked round the room, and, seeing none of the photographs, asked where they were. This gentleman showed surprise at being asked such a question, and asked what photographs I referred to, and where they were. I told him I had travelled from Montreux at the request of the Royal Institution some seven hundred miles, and that some one had grossly blundered in not obtaining the photographs as arranged. He sent off to the Polytechnic Institute, and about 8.30 a portfolio containing a few prints (not those referred to in Mr. Fyfe's note) was obtained. There was no suitable place to arrange them, so the majority were left in the portfolio. I was offered no opportunity whatever of explaining or describing the instrument, and at 11 p.m I left. Thus, I travelled some seven hundred miles at the request of the Royal Institution at a cost of 5*l.* for railway expenses alone, for the privilege of putting up and taking down an instrument. I was not spoken to during the entire evening by any one on behalf of the Royal Institution. I leave your readers to form their own opinion on the matter, and, if, as I think very possible, others have received similar treatment to myself, I hope they will come forward and say so, so that, if possible, public opinion may be brought to bear upon what looks very much as if the Royal Institution catered for their own members at the expense of outsiders.—I am, yours, &c.,

February 11, 1896. R. W. STEWART, *Colonel* (LATE) R.E.

RE THE RECENT LIMELIGHT COMPETITION.

To the EDITORS.

GENTLEMEN,—In reply to Mr. Scarborough's letter, permit me to say that if any observations contained in my letter can be considered as reflecting upon the conduct or honour of Mr. Scarborough or any of the gentlemen present, they were not so intended by me, and I can only beg of them to accept my most sincere apology, and to believe me when I say that I shall be extremely pleased if the same gentlemen can be prevailed upon to officiate again, and I should be certainly wanting in justice too, if I did not also say that I consider Mr. Scarborough's conduct throughout the contest was marked by a spirit of the utmost fairness, although there are points in his letter upon which I suppose we must agree to differ; but I must take this opportunity of correcting Mr. Scarborough's figures, viz.—·072 against ·085—upon the difference of bore of the nipples the proportion of which is, I believe, ·18 or between a fifth and a sixth, not nearly a third, as stated by him.

I am quite agreeable to accept Mr. Scarborough's challenge, although it will entail considerable inconvenience upon me, having over 120 miles to travel; but, as the challenged party, I think the right to name the conditions of the contest rests with me, and these are:—

1. That the contest be public as heretofore, in the lanterns.
2. That Mr. Scarborough and myself each work his respective jet.
3. That I have the liberty to use a mixing chamber of as large a diameter as Mr. Scarborough, and not, as previously, to be handicapped by fighting with a mixing chamber only ⅝ in diameter against one three or four times that size.
4. That in the event of a dead heat the jet consuming the least gas be declared the winner.
5. That neither of the competing jets be so large as to be unavailable for use in lanterns of maximum commercial size without alteration.
6. The loser to bear the out-of-pocket expenses of the competition.

Lastly, to make the contest, if possible, satisfactory to all parties as a final solution of the jet question, and to give Mr. Scarborough an opportunity of doing his utmost in this direction, I mention the fact that I have since the contest constructed a jet of rather more than double the illuminating power of the one I used on January 22, the full particulars of the trial of which I think he will find in the report of the meeting of the Bristol and West of England Amateur Photographic Society, which should appear in the next issue of THE BRITISH JOURNAL OF PHOTOGRAPHY.

Any minor details I shall be happy to arrange with Mr. Scarborough privately.—I am, yours, &c., G. W. GWYER.

Bourneville, Sneyd Park, Bristol, February, 17, 1896.

FILING OF TRADE CATALOGUES AT THE PATENT OFFICE.

To the EDITORS.

GENTLEMEN,—A few months ago some correspondence appeared in the electrical trade papers on this subject, and the attention of this Chamber was recently called to the matter. The following letter to the Patent Office and the reply thereto may be of interest to your readers, and the publicity given to the same through your paper may be the means of rendering the collection of trade catalogues at the Patent Office still more complete.—I am, yours, &c., KENRIC B. MURRAY, *Secretary*.

Botolph House, Eastcheap, London, E.C.

[COPY.]

SIR HENRY READER LACK, *Comptroller General, Patents, Designs, and Trade Marks Office, 25, Southampton-buildings, Chancery-lane, W.C.*

SIR,—The attention of this Chamber has been called to the fact that the Librarian of the Patent Office of the United States of America is making a collection of illustrated and other trade catalogues, price-lists, circulars, and other similar publications, for reference by those instituting inquiries in regard to patents, designs and trade marks, or making use of the Patent Office Library.

I am desired to say that in the opinion of this Chamber such a collection of records in your department would be exceedingly valuable, and am directed to bring the suggestion before the authorities of H. M. Patent Office as one which it would be well to adopt.

By this means there would be permanently preserved an enormous amount of extremely useful material which might on occasion elucidate the meaning of many trade terms and usages.

If such a collection and filing were adopted by the Patent Office, it would, no doubt, be extremely serviceable, and be largely resorted to by those interested in patents, designs, and trade marks.

I am desired to express the hope that this suggestion will receive the careful consideration of the authorities of H. M. Patent Office, and I shall be glad to learn their decision in the matter.—I am, Sir, yours faithfully,

January 27, 1896. (Signed) KENRIC B. MURRAY, *Secretary*.

[COPY.]

THE SECRETARY, *The London Chamber of Commerce, Botolph House, Eastcheap, E.C.*

SIR,—I beg to acknowledge the receipt of your letter of the 27th inst., suggesting, on behalf of the London Chamber of Commerce, that a collection of illustrated and other trade catalogues, price-lists and similar publications should be made and filed in the Patent Office Library, and in reply to inform you that the nucleus of such a collection was formed some twenty years ago, and has since that date been gradually extended.

In view, however, of the suggestion of the London Chamber of Commerce, I shall be happy to consider how far it may be possible to render this collection more complete and to make it more easily accessible for public reference.—I am, Sir, your obedient Servant, (Signed) H. READER LACK.

25, Southampton-buildings, Chancery-lane, London, W.C. January, 29, 1896. *Comptroller-General.*

RUSSIAN PHOTOGRAPHIC PAPERS.

To the EDITORS.

GENTLEMEN,—In THE BRITISH JOURNAL OF PHOTOGRAPHY, for February 14, I notice a statement that a photographic journal has been started in Russia. It may interest your readers to know that there exists a monthly journal, *Photographe Loubietel*, published at St. Petersburg, and edited by Captain Lavroff, which is now in its seventh year at least. Until quite recently it possessed a rival in the *Photographicheski Westnik*, also of St. Petersburg, which was founded in 1888.

Most of the back volumes, as well as current issues of these periodicals, are to be consulted in the Royal Photographic Society's library, by those who, like yourselves, appear to be familiar with the language.

The journal of the Imperial Russian Polytechnic Society also devotes much of its space to photographic matters.—I am, yours, &c.,

R. CHILD BAYLEY.

Answers to Correspondents.

*** *All matters intended for the text portion of this* JOURNAL, *including queries, must be addressed to* "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 2, *York-street, Covent Garden, London. Inattention to this ensures delay.*

*** *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

*** *Communications relating to Advertisements and general business affairs should be addressed to Messrs.* HENRY GREENWOOD & Co., 2, *York-street, Covent Garden, London.*

PHOTOGRAPHS REGISTERED :—

A. H. De' Ath, Bank-street, Ashford, Kent.—*Three photographs of Alfred Austin, Poet Laureate.*

CONSTANT READER.—W. L. NASH. Probably in our next.

FACTORY ACT.—A BRIGHTONIAN. You omitted your name and address.

COL. J. E. GURBINS.—Thanks for suggestion. It will probably be acted on.

LENS FOR ENLARGING.—BEGINNER writes: "Can I use the lens with which the original negative was taken for enlarging, or is a special lens required?"—In reply: The first lens will answer all purposes.

RATIO OF STOPS.—D. ANDERSON writes: "Can you let me know through your Inquiry column how the size of a stop or diaphragm is ascertained for a lens of a given focus?"—Simply divide the focus of the lens by the size of the stops.

DEXTRINE FOR MOUNTING.—TOUCHSTONE. Although this would be a convenient mountant, it should not be used for silver prints. The dextrine met with in the shops is almost always acid, sometimes strongly so, which would act injuriously on the photographs.

CHIPPED LENS.—R. RODGER. The two chips caused by the accident will not injure the working of the lens if the places be blackened over with a little black varnish to prevent reflections. There will be a slight loss of light, but so trifling that it will not be noticed in working.

COPYRIGHT CHARGES.—J. E. HUNT says: "Recently I have heard from a publisher, *re* one of my copyright photographs. He asks if he might use it for publication. The photograph is of a very popular minister. What fee should I ask?"—Possibly a fee of 1*l.* 1*s.* would meet the case.

VARNISH.—TACKY. If the varnish is of the brand mentioned, we feel assured that the fault does not lay with that. The only way we can account for the non-drying is that the hyposulphite of soda was not all washed out of the film. Hypo left in the film will often prevent the varnish from drying hard.

SUBSTRATUM FOR LANTERN PLATES.—R. E. C. asks how the substratum is made that is used in making lantern slides by the wet-collodion process? —Put the white of an egg in a Winchester quart bottle, add a quart of water and a few drops of ammonia, and shake it up vigorously for a few minutes, then filter through paper for use.

FIXING BATH.—H. H. EALY wishes to know the proper strength of a fixing bath for bromide papers, and the time for which the prints should be immersed, opinions seeming to be widely different on the point.—In reply: The best strength is four ounces of hypo to the pint of water. If there is plenty of solution, and it is fresh, *i.e.*, has not been used before, the prints will be thoroughly fixed in fifteen minutes, and there will be no gain in leaving them in any longer.

ENCAUSTIC PASTE.—J. BATEY. The formula for this, as given in the ALMANAC, is quite correct. There may be two causes for your want of success: First, the use of impure wax; secondly, faulty application. Rub a little of the paste over the print with a piece of soft flannel, and then polish off with a second piece. A thin coating only is required. The same flannel can be used over and over again. Indeed it improves by use until it becomes saturated with the paste.

NIGHT PHOTOGRAPHY.—W. PINDER says: "I have got an order to take an instantaneous photograph of a large group at night at eight p.m., out of doors, in the main street. Kindly let me know if it is possible. If so, I should like to know the best way to illuminate the group. We have no electric light here."—It can be done, of course, with a strong light. Magnesium flashlights are the only things that can be used if the work must be instantaneous. Several lights should be used, and placed so that they evenly illuminate the group, and be fired simultaneously.

SECONDARY IMAGE.—PETTINGELL inquires: "How do you account for the enclosed, I mean the seeming shadow of the house inside the other? We are quite sure there were no double exposures, or any way in which the light could get in. These prints are off two different plates taken after each other (at the same time) on a rather dull and windy morning. Taken with a 12×10 camera and lens."—The second image is caused by a minute hole in some part of the camera, probably in the front, near the flange of the lens. This has acted the part of a "pin-hole" camera and produced another image.

CRACKS ON ALBUMEN PRINTS.—E. BLISS. With highly albumenised paper cracking of the albumen is no uncommon thing if the prints are allowed to curl up as they dry, then they crack when they are uncurled. The trouble may be avoided by mounting the prints while they are still wet, or drying them between blotting-paper, so that they are kept flat the while.

EXPANDED FILM.—MAC says: "I took a negative of a ball-room on Saturday which cannot be done again. When I took it out of the fixing bath, it had nearly all left the glass, so I removed all the film, with the intention of putting it on a larger glass, but I find that the part of film that left the glass in fixing bath has expanded. Is there any way of contracting it again?"—If the film had been put into spirit at the time, it would have gone back to its original size. If it is still wet, it will probably do the same now. If it has been allowed to dry, the case is doubtful. The best thing we can suggest is to soak the film for some hours in water, and then to put it into spirit.

CONDENSER.—ENLARGER writes: "As we wish to be independent of daylight for enlarging, we should like your opinion as to the best way to get, say, whole-plate negatives enlarged, evenly illuminated, and the exposure not too slow. Condensers are said not to give satisfactory results, and without them very likely the exposure would be too slow. An answer will oblige."—The best way will be to use condensers. They do give satisfactory results, and are generally employed where artificial light is used. Of course, the light must be in the proper position, and the condenser of sufficient size to evenly illuminate the negative. This, for the size named, must not be less than eleven inches in diameter.

STAMP PHOTOGRAPHS.—F. H. INQUIRY asks: "1. Where can I purchase a camera with twenty-five lenses for postage-stamp photographs? I want to take twenty-five on a cabinet plate, five in a row. 2. Where can I purchase a perforating machine for dividing the aforesaid postage-stamp photographs? 3. What is the method of gumming the backs—if any special—and where to purchase the gum best for the purpose? 4. How to produce those beautiful rich brown tones on P.O.P.—not chocolate—I have seen produced by several first-class photographers? I use the sulphocyanide toning bath, and get good tones, but they are too much like the ordinary silver print tone, and certainly do not approach in any way the tones I speak of."—1 and 2. Any of the large dealers will supply the necessary apparatus. 3. Gum arabic, with a trace of glycerine, brushed on the back. 4. Almost any tone may be obtained with the sulphocyanide bath from suitable negatives.

A LENS FOR GROUPS.—BETA writes: "Can I use one combination of my portrait lens as a single lens to take a group by? What stop should I have to employ to get good definition? Would the exposure required be longer than that when using the entire lens?"—In reply: The front combination will most likely be found to be satisfactory, but it should be turned round, so that its convex surface is towards the ground glass. It will certainly have to be stopped down to *f*-11 or more to get the best definition; but, if very sharp outlines are not required, it might be found to work well at *f*-8. The exposure will certainly be longer than is the case when the entire lens is employed. It is sufficiently accurate to expose in proportion to the stop employed, in the usual way, giving, with *f*-11, an exposure about eight times that which would be given were the portrait lens, with open aperture, in use. Theoretically, a little less exposure would suffice with the single lens, since this has fewer reflecting surfaces to diminish the light, but in practice this difference is too slight to need to be taken into consideration.

A MEAN TRICK.—S. W. writes as follows: "Our vicar came to me three or four weeks ago to have his portrait taken to sell at a bazaar. He said he would require a large number of copies, but he would pay for the sitting and order the number of copies required afterwards. I took three negatives, though I only charged him for one, and sent him a proof from each. As no order followed, I wrote him, and had a reply, saying the portraits were very good, but he would not require any more. I found, when the bazaar was on, that he had sent the proofs to a London house that advertises cheap copying, and had several dozens made, which were sold at eighteenpence each. Though they were wretched things, they were said to have been taken by me, and they will do me an injury. Have I any remedy under the Copyright Act?" —No; we fear not. You might, however, advertise in the local press that the prints sold at the bazaar were not your productions as alleged. By that means you will set yourself right with the public, and, at the same time, expose the mean trick.

TONING BATH.—PSEUDONYM says: "Regarding the combined bath for gelatino-chloride prints, I have used Solio and Criterion paper for more than three years, and, on the whole, got on well; but sometimes it happens that it is impossible to get anything but foxy tones, no matter how much gold is used. Can you suggest a reason why it is? The Eastman Company, in their instructions, tell one to put a piece of litmus paper in the bath before toning, so that only uniform acidity should be maintained; but they don't say what to use to make the bath more alkaline or acid, as the circumstances may require. Can you inform me as to this? Why is it necessary to use a lead salt with the gold, lead salts being always regarded with suspicion in a toning bath? Lastly, can you tell me what purpose each of the ingredients is used for, except the hypo?"—The reason good tones are not obtained is that the bath is out of order. Too great an acidity of the bath may be corrected by a little chalk. Why the lead salt is used is because the combined bath does not work well without it or the other ingredients. The combined bath is not to be recommended on account of its uncertain action and results. Why not use the sulphocyanide bath? It is in every way preferable to the combined bath.

JOURNAL OF PHOTOGRAPHY.

No. 1869. Vol. XLIII.—FEBRUARY 28, 1896.

Contents.

EX CATHEDRÂ.

Mrs. L. R. Stuart-Wortley, of 55A, Gloucester-place, Portman-square, W., writes to us: "I am the widow of the late Colonel Stuart-Wortley, who was famous for his sea and sky studies and life studies. I am now carrying on photographic work in memory of him, and have all the original photographs he took, which I have made copyright, and am exhibiting them in my little studio. It has been suggested to me that these studies should be seen by artists and students of nature, to whom they would be most valuable and helpful, and, no doubt, there are many young men who have never seen any of these photographs."

* * *

We are happy to give publicity to Mrs. Stuart-Wortley's communication. The photographs are on view at her studio, at the address given, on Mondays, Wednesdays, and Thursdays, between two and seven.

* * *

The most recent One-Man-Show at the Camera Club included a number of works by Mr. Henry Stevens. The photographic art of Mr. Stevens is many-sided. At one time it seemed as if he was inclined to devote himself exclusively to the representation of flowers by means of photography—a branch of work in which he was signally successful. Then his fox-terriers, next his cats, and finally both, characteristically grouped, occupied his attention. Of these varieties of work, and the opportunities they present for photographic treatment, Mr. Stevens showed many examples and illustrations in the display which was on view last week. Snow scenes and portraiture have also come within the scope of his powers, and the total result was a collection of signally good and faithful photographs. If we may presume to hazard a general opinion with regard to Mr. Stevens's work, we would say that, in the field of animal portraiture, he has not yet fully developed his own capabilities or exhausted the opportunities it offers.

* * *

Mr. F. F. T. Weeks, a clever artist, of 263 Canu Hall-road, Leytonstone, whose lantern-slide reproductions of life studies we have already had occasion to favourably notice, is making a speciality of touching up photographs which have to undergo the ordeal of phototypic reproduction. The special features of Mr. Week's work are thus summarised by himself:—"Halation and movements rectified, detail strengthened, and all faults and imperfections accurately made good and improved. Figures, backgrounds, skies, and scenic surroundings added, obliterated, or altered, as desired. Enlargements produced and improved for process from any basis. 'Mosaics' and 'composites' artistically and pictorially made up with or without fancy and appropriate borderings, lettering, &c. Old engravings, &c., bleached, improved, and worked up. Old portraits, photographs, &c., reproduced equal to new." In giving Mr. Weeks the benefit of this publicity we are animated by the wish to see others of our readers profit by his example. Assuredly the "working up" of photographs for reproduction is a branch of the art that admits of remunerative cultivation.

* * *

At Marlborough Hall, Regent-street, kinematographic or kinetoscopic pictures on the screen are being shown by means of the contrivance "invented" for that purpose by Messrs. A. and L. Lumière. Setting aside some minor imperfections of vibratoriness and "light streaks" rapidly flashing across the pictures, the representation of lifelike movement on the screen was very successful on the occasion of our visit last week. We described and illustrated the kinematograph at p. 11 of the Lantern Record (Supplement to this Journal) for February

7 last. In their official circular relating to these projected photographs of animated scenes Messrs. Lumière say: "The photographs, taken on a continuous band at the rate of 900 per minute, are by means of the electric light projected life size upon a large screen at exactly the same rate of movement, so that a changing picture is produced perfect in its fidelity and naturalness. It thus becomes possible to reproduce scenes and events of historic importance, of political, social, or sporting interest, with such perfect accuracy of detail, change, and movement, that a roomful of people in London may enjoy the perfect illusion of being actual witnesses of the spectacle." There is a mechanical rhythm and jerkiness in the movements of the figures as shown on the screen which possibly combats the theory that the projection of the pictures is effected at the same rate of movement by which they were taken. For all that, the system is wonderfully interesting and effective, and, for a time at any rate, kinetoscopic pictures on the screen will assuredly be popular.

IODINE AS AN ELIMINATOR.

When it is necessary to intensify a negative after fixing with hypo, it is a common practice to resort to the employment of what has been called an eliminator, to remove the last traces of that agent and its compounds, though it has frequently been pointed out in these pages how wrong the practice is in principle. Of the various agents so employed, tincture of iodine amongst others has been recommended, but it is probably one of the very worst that could be so employed, and, in many cases, does far more harm than good, since it only transforms any hypo that may be present into sodium tetrathionate, which is, at least, as dangerous. But iodine is frequently employed before intensification, not as a hypo eliminator, but to convert a small surface portion of the image into iodide of silver, and so facilitate the subsequent deposition of silver.

This application of iodine is really useful, and in every way legitimate, but, in adopting it, what we have said above should be borne in mind. Now, many operators, both with gelatine and collodion plates—we speak more especially of emulsion films—employ tincture of iodine in this manner, trusting to it to do duty as a hypo eliminator as well; and here danger comes in. If there be any considerable quantity of hypo present—and this means that there must of necessity be also some silver remaining in the form of the double hyposulphite—the iodine will convert the silver into iodide, and render it necessary to refix the plate, and, of course, the trouble of washing again is incurred. If the quantity of soluble matter remaining be very small, there may be no visible precipitation of iodide of silver to warn the operator of danger; but, upon proceeding to intensify, it is almost certain to make its presence palpable by a strong discolouration in the shadows.

Whenever it is necessary to adopt the iodine treatment previous to intensification, unless the fixing has been already performed with cyanide of potassium, a solution of that salt should be flowed over the plate previous to the application of the iodine; or, better still, if the image will bear a little reduction, flood the film with iodine before the cyanide. The iodine will convert any hyposulphite of silver into iodide, which the cyanide will remove, as well as any slight veil that may be present, and a moderate washing will remove the final traces of silver. Then the surface may be iodised to any extent, and intensification proceeded with in safety.

It is worth while to bear in mind that, of the three fixing agents that have been mentioned, cyanide acts most freely upon iodide of silver, and upon bromide and chloride in the order named. Hypo dissolves silver chloride most readily, bromide next, while its action upon the iodide is very feeble.

THE CARRIAGE OF GAS CYLINDERS.

We are still without the report of the experts appointed by the Home Office to inquire into the charging, transmission, &c, of gas cylinders, although we are fast approaching the end of the lantern season, and the railway companies still place vexatious restrictions on the conveyance of the cylinders. Whatever may be the report of the Committee, it by no means follows that it will influence the railway authorities as to their regulations and prohibitions. We have a pretty shrewd idea that, notwithstanding these, charged cylinders are often carried, surreptitiously, as personal luggage.

Only a week or two back we alighted at a suburban station of a railway that refuses the conveyance of gas cylinders on any terms. Out of the same train got, apparently a young curate, with a considerable amount of impedimenta—more than he could conveniently carry. It consisted of a large square black box, on the top of which were strapped three long deal boxes, about four inches square. He had also a stout leather bag. The box package seemed to cause no inconvenience to this muscular young Christian, but the bag did. Evidently by its weight it contained something heavier than a cassock or surplice.

At the exit of the station the services of an outside porter were invoked, who took the bag, but soon found it necessary to hoist it on his shoulder for convenience of carrying. One could not help speculating on what the packages contained. We had no doubt whatever but that the smaller long deal boxes contained lantern slides, and as little doubt that the square box held a lantern. But the leather bag? Except for the fact that all the stations on that line were placarded with bills, stating that cylinders of compressed gas would not be carried as personal luggage, or admitted in the company's stations for any purpose whatever, and the fact that the gentleman was in clerical garb, we should have had no hesitation in saying that the strong leather bag contained a couple of ten-feet cylinders of oxygen and hydrogen gas. Later on, we heard there was to be a lantern show with the limelight, by a reverend gentleman, to the children of a Sunday school in the neighbourhood.

Photographs of a "Flying Man."—Some of the most interesting of recent photographs are those of Herr Lilienthal, whom photographs of undoubted *bona fides* clearly represent suspended in the air with his wings expanded. They show incontestably that he is in the air, and suspended many feet high by his curious apparatus, the whole suggesting a huge bat with an extra pair of wings some distance above and parallel to the main pair.

Liebig's Condenser.—The true name for this time-honoured piece of apparatus is at present the subject of a mild polemic. In a foreign contemporary Dr. G. W. H. Kaulbaun has a note on its origin. It appears that Liebig himself always wrote of it as Göttling's; but neither did the latter lay claim to its invention, for he clearly attributes it to C. E. Weigel, Professor of Chemistry and Botany at Greifswald. The first description with diagram of this indispensable adjunct to the laboratory was published thirty years before Liebig was born.

Marey's Chrono-photographs.—Those who are interested in the photographing of a series of views of various animals executed with phenomenal rapidity will find much to interest and instruct in a new work on the subject, which this philosopher has recently published. His plan of working is different from that of many others. In some cases a large number of photographs are taken on one plate, the exposures varying from one-five-hundredth to one-tenth of a second, fogging being obviated by placing a background of unilluminated black velvet behind the subject, which receives full sunlight.

A Novel Use for the Röntgen Rays.—According to a Vienna correspondent (but it is not necessary to believe everything written about the latest popular science) an application of a very practical nature has been made with the new form of energy. In the Museum of Natural History in that city is stored an Egyptian mummy, which is esteemed as very valuable. In appearance it is like the mummy of a human being, but certain inscriptions upon it suggest that a bird—an ibis—lay beneath the wrappings. It is too rare and valuable a specimen to be subjected to possible injury by unwrapping it, so it was determined to Röntgenate it. It was taken to the School of Photography and operated upon accordingly. The sciograph obtained showed clearly the outline of a large bird.

Cheap Aluminium.—It is stated that new works for the production of this metal on a large scale are about to be erected in Norway. A syndicate of German and American capitalists has purchased for a sum of 800,000 kroner, or over 30,000*l.*, the estate of Hafslund, near the great waterfall of Sarpsfos. It is intended to utilise the water power of the falls in a similar manner to that adopted for the falls of Foyer in Scotland. With all the new sources of output it is inevitable that the competition will bring down the price of the metal, and with the recently described improvements in soldering we should be within measurable distance of having aluminium mountings for lenses or cameras vended at a price little, if any, in excess of what would be charged for brass.

The New President of the Royal Academy.—Sir John Millais has been unanimously elected President of the Royal Academy in place of the late Lord Leighton. The election to this important office is a very simple affair. Each member at the meeting is handed a list of the forty Academicians, and places a mark against the name of the one of his selection. The Chairman is the oldest Academician present; he opens the papers and announces who has been elected. Although the election is so much more simple than that to less important presidentships, other formalities have to be gone through afterwards. Following the signing of the patent and the transfer of the gold chain and medal of office, the new President is presented to the Queen. The badge, it may be mentioned, which is enclosed in a glass case, was presented to the Academy by George III. It is always worn by the President on all great occasions, suspended from his neck by a massive gold chain. Will the Presidency of the Royal Photographic Society ever attain this importance?

The Kinetoscope and Prize Fighting.—The sporting fraternity, both here and in America, have been in a state of excitement about a projected fight between a couple of noted pugilists. On Friday last the fight came off in Texas, and a Reuter's telegram says: "The weather was cold, and a slight rain was falling. Elaborate preparations had been made for taking a series of accurate pictures of the fight by means of the kinetoscope." Of course, we do not know how the negatives turned out; but, as it is mentioned that rain was falling at the time, the result may be doubtful. If it is successful, it will, doubtless, prove highly successful to the sporting advocates of the "P. R." Some, on the other hand, may consider it a demoralising exhibition and a prostitution of modern science. However, Mr. Birt Acres, with his lantern kinetoscope, has depicted on the screen some excellent "boxing matches," which have been highly appreciated by those who have seen them, although they have not been those who would be strongly opposed to prize fighting There is, however, a difference between a friendly boxing contest and a prize fight, but one will look very much the same as the other in the kinetoscope.

Early Colour Photography.—A paragraph has been going the round of the lay press, and has been copied in one or more of our contemporaries, to the effect that, according to Dr. Vogel, Dr. Selle's method of photographing in natural colours is thirty years old, and is the invention of an Englishman named Cullen, though since improved upon by Ducos du Hauron, Dr. Albert, and himself. One likes to see credit given where it is due, but the Englishman's name is Collen, not *Cullen*. It may be interesting to our countrymen to know that Mr. Henry Collen, a portrait painter residing at St. Albans, was one of the very earliest workers of photography in England. We believe we are correct in saying that the first photographic lens the late Mr. Andrew Ross constructed, for portraiture at least, was for Mr. Collen. This lens was of the doublet form, and was non-distorting. It consisted of two plano-convex lenses achromatised, with a diaphragm between them. It had a very round field, so much so that the sensitive paper (for this was in the pre-collodion days) had to be pressed into part of a sphere between two glass plates, when it was used for portraiture. This lens was made for Mr. Collen in 1841, and is still preserved as a relic of the past.

Alum and Hypo.—It is well known that, when solutions of these substances are mixed, a precipitate of sulphur takes place, and the fear of some untoward accident governing the permanency of the film prevents the photographer putting a plate out of the hypo solution into alum till he has well washed it; but it should be borne in mind that the presence of gelatine and other substances materially retards, if it does not actually prevent, the precipitation in certain mixtures that, without its presence, would throw down a deposit. Hence, in case of frilling, it is not uncommon to see a plate thrown directly into alum water out of the hypo solution without apparent injury. Light has been thrown on the matter by the investigations of Herr N. Pringsheim, who, placing a gelatine septum between two solutions which, when mixed, produce a precipitate, made notes of the result under varying conditions. Bearing upon the topic we have under review, he found that a precipitate took place in the gelatine, and continued to increase under certain conditions. The direction of that increase was sometimes to one and sometimes to the other side of the septum. When the strength of the solutions was not equivalent, he found, in many instances, that the direction of the increase was towards the weaker solution. It might thus well follow that, in the case of a hypo-containing plate put into alum, so long as the alum was present in solution of weaker equivalence than that of the hypo, any precipitate that occurred would be towards the surface of the film, whence it could be rubbed away.

Another Fatal Cylinder Explosion.—Just now the explosion of a gas cylinder, particularly if attended with fatal results, is likely to militate against the use of compressed gases by those of an extra-nervous temperament, as well as not being conducive to their freer transit by the railway companies. Last week an explosion occurred in the chemical laboratory of Messrs. Redwood & Hailes, in Red Lion-square, Holborn, when the unfortunate experimentalist was killed and another was injured. According to a daily contemporary, the deceased was "seen holding a small oxygen gas cylinder over a gas-combustion stove, and the next moment the explosion occurred." We call special attention to this accident, because prominence has been given in the daily press to "another oxygen cylinder explosion." At the inquest (which was adjourned) it was stated that the cylinder with which the deceased was working was empty; but, even if it contained oxygen, heating it over a combustion furnace, and producing an explosion, must not be taken as militating against the safety of compressed gases for the purposes for which they are ordinarily used.

It is amusing to note the different versions of the unfortunat

accident as they appear in the press. One says: "Two young men were engaged in mixing a quantity of acid in a large steel cylinder. By some means an explosion occurred." Another has it that "the gas engine, at an artistic-card manufactory, without the least warning, suddenly exploded, which caused the greatest consternation amongst the *employés*, and, after it had subsided, two of the girls were found to have been so seriously injured that they died shortly afterwards." It is also stated in this account that "the two bodies were conveyed from the premises by the back entrance in Eagle-street."

JOTTINGS.

I HAD occasion last summer to pass an unfavourable criticism on the new premises of the Royal Photographic Society in Hanover-square. To my knowledge not a single member, either orally or in writing, has spontaneously disagreed with me. The terrible over-crowding of the meeting-room—an apartment which has always impressed me as combining the features of a disused swimming bath, a soup kitchen, and a glorified rabbit hutch—on the occasion of Mr. Alan Swinton's demonstration of electrography has, I am pleased to see, induced two or three contemporary writers to point out the inadequacy of the accommodation provided for members, which, of course, is felt with extra poignancy when unusual demands are made upon the seating accommodation.

It was most unfortunate that, on the occasion of the Annual Meeting, with a large number of members and visitors eagerly awaiting Mr. Swinton's demonstration, the opportunity of ventilating this subject could not be taken. Under the circumstances, a discussion of that nature could only have been of a mild, hasty, and perfunctory character, would not have been relished by the visitors, and might have seemed ungracious to Mr. Swinton; but it is to be hoped that an early opportunity will be given members to express an opinion on the question of the premises and other matters, for I understand that the application of the gag, on the one night of the year when many members of the Society looked forward to discussing its business affairs, has provoked a feeling of great resentment. There was one passage in the report of the Council, implying that the new premises met with the approval of members, which was a piece of imaginative writing that simply makes many of us smile, and at the same time is picturesque enough to drive a novelist into paroxysms of envy.

There are some things which are managed better in Germany than in England, especially in scientific matters. When Röntgen's discovery was announced, he was sent for by the German Emperor, and, after repeating his experiments, was honoured with a decoration, in official recognition of his work. In this happy land scientific progress is too unimportant a matter to attract the patronage of our rulers and the Government, when not engaged in plotting the annexation of big bits of distant continents, seem never so happy as when perpetrating such wicked jobs as the payment to the Duke of Saxe-Coburg and Gotha (a foreign potentate) of the vast sum of 10,000*l.* a year for a month's residence out of twelve at Clarence House, St. James's. I'm quite sure that all but a handful of Court toadies would be only too happy to relieve His Royal Highness of his obligation—at the price.

I started the previous paragraph with the intention of pointing out the need which science in general, and photography in particular, daily feels for the existence of specially provided facilities so that public experimental work of importance can be undertaken as occasion may demand and at the minimum of expense. What is wanted, in fact, is a public experimental laboratory—as free and open as are our museums and libraries. It is nothing short of scandalous that the initiative in verifying Röntgen's experiments in this country should have been left to private gentlemen and enthusiastic experimentalists like Mr. Gifford and Mr. Swinton, who went to great trouble and expense in the matter, and that facilities for the work were not available to scientific students whose purses are not overloaded with money. What could we not do with that 10,000*l.* a year! How valuable in the cause of photographic research and progress would be but a twentieth part of it if judiciously expended by the Royal Photographic Society.

A photographic laboratory with a permanent staff of investigators, however small, is, indeed, badly needed. Frequently in matters of theory, and now and then in matters of practice, we are obliged to take much for granted that would better conduce to accuracy and certainty of knowledge if it could receive the stamp of official verification or disproof. Orthochromatic photography supplies a case in point just now. Careful readers of these pages during the last few weeks have noticed the growth of a polemic on this subject, which personal feeling will probably prevent coming to a head. A and B (able practical photographers) maintain that correct colour renderings can be obtained on plates not specially sensitised for the purpose; C and D (persons of great eminence—in theories) deny the power of "ordinary" plates to give what we call "orthochromatic" effects. Now, surely, here is a matter which could be settled without much difficulty, and in which the services of a kind of English Dr. Eder would be invaluable. In the meanwhile the sooner those gentlemen who maintain the "orthochromatism" of ordinary plates put the photographic public in possession of the wonderful secret they appear to have discovered of making silver haloids sensitive in the camera to bands of the spectrum which nearly a generation of experimentalists has shown have almost no effect, the sooner they will earn the gratitude of all photographers. In the meanwhile, if I was the Britannia Works Co., Messrs. Edwards & Co., Messrs. Lumière, or Messrs. Cadett & Neall, I should still "list" orthochromatic plates and yellow screens. There is no "slump" in them visibly near at hand.

"Herkotype" is the name that has been given to the process of photogravure—minus the photography—which Professor Hubert Herkomer, R.A., has "invented" for the purpose of enabling an artist to autographically reproduce his pictures, without jeopardising what used to be called the "artistic merit" of them through the use of such a vulgar and debasing medium as photography. There are several examples of herkotype in the current number of *The Studio* by Professor Herkomer, and—nobody else. The pictures seem really good, and so do the other (half-tone) reproductions in the same issue. It has already been pointed out in these pages that herkotype as a reproductive process is intrinsically open to objections which photogravure can successfully defy. So far as can be learned, no artist but Herkomer himself has yet used this method of painting on metal plates for multiplying his pictures. Unless I am much deceived, it will have to be taught, and learned, at Bushey—that rare shrine where the worshippers of Herkomer do homage to their deity and "art," and gratefully pay so many guineas a year for the double privilege.

By the way, I have to thank the editor of *The Studio* for a couple of phrases, which I shall carefully make a note of for use at the next photographic Exhibition I go and look at. Reviewing Emerson's *Marsh Leaves*, a writer in *The Studio* (a publication which grows in beauty and value every month) says the etchings in that volume "will go far to widen the existing gulf which yawns between the crowds who depict too much of everything with harrowing insistence, and the few, such as Dr. Emerson, who impose upon their records an impressive reticence!" "Harrowing insistence" is good, very good; but "impressive reticence" is really a gem of inscrutably, irreconcilable, critical phraseology, which is eminently calculated to "knock 'em in the Old Kent Road." Armed with the phrases "harrowing insistence" and "impressive reticence," with their obvious cross changes "impressive insistence" and "harrowing reticence," I calmly await the next exhibition of the Photographic Salon. Thank you, Mr. *Studio*.

COSMOS.

CHEMICAL DEVELOPMENT IN PROCESS WORK.

SINCE the introduction of dry plates into process work, the question has cropped up in various forms as to whether the different form of development, or perhaps, to speak more accurately, the different

constitution of the image produced by chemical development, is as well adapted to the rendering of line and dot work as the old wet plate. Most operators at the outset experience greater difficulty in securing absolute clearness in the fine lines when using dry plates—by which I mean more especially gelatine plates—than is the case with wet collodion, and to a certain extent the same thing is found with collodion emulsion films. But the question is, Can the result be truly attributed to the fact of the image being formed within the film?

During the past few months I have developed some hundreds of negatives of line subjects, mostly by means of alkaline pyro and other developers of the "chemical" class, some on gelatine, but the majority on collodion plates, and, from the observations I have made, I am strongly inclined to believe that the apparently greater tendency to filling up of the finer lines, or the "closing up" of the dots in the high lights of a half-tone negative, are not due to the method of development, nor to any greater tendency to "lateral spread" of the image, but rather to causes dependent upon the exposure and the optical conditions.

In the use of gelatino-bromide plates in conjunction with the screen, it has been found desirable, in order to produce a similar result, to employ, not only a smaller stop, but also a less distance between the screen and the plate than if a wet plate were being used; but, when a collodio-bromide plate is substituted, if the reverse conditions do not prevail, at least there is very little difference required in the treatment as compared with a bath plate, although the development is practically the same as in the case of gelatine.

In order to explain the difference, it may be laid down as an axiom that, in order to secure an absolutely clear and sharp rendering of a fine line or dot, it is necessary that it be projected on to the sensitive surface with absolute sharpness and crispness, whether that surface be wet collodion, gelatine, or collodion emulsion. Carey Lea, in his admirable *Manual*, in speaking of copying, says: "To obtain a fine copy of a line engraving in which the hair lines are to be faithfully and sharply reproduced, requires a good lens, well managed. The stop must be very small, not exceeding *f*-60, or one-sixtieth of the focal length. The lens should be a large one." Now, although the copying lenses of the present day are, no doubt, far superior in point of definition to the best of the period at which he wrote, the above statement contains the gist of the matter, namely, in order to secure clear, sharp lines, a small stop must be used; not merely a stop that will give apparent or visual sharpness upon the ground glass, but a degree of sharpness that will bear a considerable amount of magnification.

Although pure line and half-tone work are essentially different in principle, the bearing of the principle on the fact that gelatine plates require a smaller stop than collodion under similar conditions is not far to seek, and the same arguments may be used in both cases. Let me take a half-tone negative to illustrate what I mean; or, perhaps, better still, let us make a series of varying exposures on a plain white sheet of paper, using a ruled screen in front of the plate. When the image of the screen is examined on the ground glass, or with a compound microscope on a sheet of plain glass, a series of dots will be obtained, varying in sharpness and intensity with the distance of the screen from the plate, and with the strength of the reflected light. But, on making a series of exposures, we shall have as many different renderings of the dots, probably not one of which represents the screen as it appears to the eye under a magnifier. The explanation of this is, no doubt, that the eye fails to recognise the gradual softening away of the edges of the light dots as seen on the focussing glass, although the sensitive plate does, and consequently, with each increase of exposure, the dimensions of the dot increase.

In precisely the same manner, though not in the same degree perhaps, when a line engraving is sharply focussed with a stop of, say, *f*-16, although to the eye, even when aided by a magnifier, the image may appear perfectly sharp, it still possesses or suffers from the same unrecognised softening of the lines, and, in proportion as the exposure is increased, so do the light lines widen, and consequently the hair lines of the engraving gradually close up or disappear. When the stop is decreased to, we will say, *f*-64, the definition is proportionately finer, and there is less softening of the edges of the lines, and consequently less closing up. I have before me as I write two negatives upon ordinary gelatine plates, the subject being a line engraving possessing considerable contrast of light and shade. One was exposed with a stop of *f*-16 for four seconds, the lens being one that, with that aperture, gives perfect visual sharpness over the whole plate; the other was exposed with *f*-40 (No. 100, U.S.) for twenty-five seconds, or equivalent exposures under the condition of light and stop. In the first the lines of the shadows and the middle tints are, to the eye at least, perfectly clear and sharp; but, as the high lights are approached, the lines become gradually more and more veiled, until the hair lines, to repeat the expressive term, are absolutely lost.

In the second negative, while the lines that are rendered with perfect clearness in the first are not appreciably sharper, the highest lights are now not sufficiently veiled to prevent their printing through on ordinary photographic paper. I should have liked to repeat the experiment with collodion emulsion, but the weather has been so unfavourable, though, no doubt, the result would have been similar, so far, at least, as the decrease of the filling up of the lights is concerned; but in this latter case, or with wet collodion, I anticipate the hair lines would have been *quite* clear.

Not as a matter of difference between chemical and physical development on the one hand, or between gelatine and collodion on the other, but purely and simply on account of the difference in sensitiveness of the different plates, in the case of gelatine the film is so sensitive to the weaker radiations that it reproduces the gradually softening lines to a degree that the collodion is incapable of doing, and consequently brings about a much greater thickening of the lines.

There is another element that should be taken into consideration in connexion with the difference in sensitiveness of the two classes of films, namely the nature of the subject photographed. It is customary to speak of an engraving as black and white, but a comparatively rough examination, especially if a magnifier be used, will prove this to be anything but the truth. The hair lines will prove to be only light grey, or, if analysed with a powerful magnifier, will resolve themselves into a series o grains of alternate black and white, and, at the same time, the fine white spaces dividing the heavy lines of the shadows will prove to be smudged or grained with black, which reduces them also to the condition of half-tones only. The lightening of the hair lines in this manner materially assists in their "filling up," especially when a quick plate is used, and the degradation of light portions of the shadows, while it does not greatly affect the sensitive gelatine plate, does so seriously with the slower collodion films.

I have had no opportunity of comparing wet-collodion or bath plates with collodion emulsion, but I have pitted the two kinds of developer, one against the other, on wet collodio-bromide plates giving, as nearly as I could ascertain by trial, equivalent exposures for the respective developers. The proportionate exposure, using pyro and silver and alkaline pyro respectively, with the same exposure, was about six to one, as far as I could judge, taking into consideration the very different characters of the two images: and, under these circumstances, there was no practical difference in the *amount* of filling up of the finer details, though it was of a different nature in the two cases. With alkaline pyro it took the form of a soft veil, filling up the interstices between the black lines, and conveying a suggestion of loss of sharpness: in the other case it was a hard, ragged thickening of the black lines, which gradually closed in, and, as it were, buried the hair lines. There was the advantage in the latter case that a clearing solution somewhat improved matters, though it did not remove the "raggedness," while, with alkaline pyro, it was comparatively useless.

It seems to me to be for line work simply a question of using a sufficiently small stop and giving a long enough exposure, when, of course, other things being equal, the more rapid gelatine plates will have a decided advantage over collodion; but, for half-tone work, the slower plates still seem to be better adapted to the purpose, since the power given by the system of working with different sized stops for different portions of picture enables us to get over the weak-

nesses of the process. This was spoken of a short time back as a "complication" in process work, but I cannot help thinking that it would be a great help in line reproduction if some similar method existed of differentiating the exposure, so as to keep back the high lights while the shadows gain force.

In conclusion, let me repeat my argument, namely, that I think much of the prejudice formerly existing against dry plates is due to the attempt to work them under similar conditions to wet, and that the difference in the results obtained under similar conditions of working is solely due to the higher degree of sensitiveness, and not at all to any inherent defects in the process, or to the action of the image or its development. W. B. Bolton.

HOW TO TAKE ELECTROGRAPHS.

We have had numerous inquiries during the last few weeks about the Röntgen shadowgraphs, as many call them, and how they can be produced, and so we propose to give sufficient details, without discussing in any way theoretical matters, to enable any one possessing the requisite apparatus to produce similar results.

The essentials are few in number, a radiant matter tube and a source of high-tension electricity being the only things necessary other than the purely photographic appliances, such as a dark slide, developing dishes. &c., which every photographer will have by him.

The radiant-matter tubes are glass bulbs, into which are sealed two terminals or wires composed of platinum where they pass through the glass, and aluminium where the wire is exposed inside the tube. Each terminal finishes up outside the tube in a little wire loop, by which it is

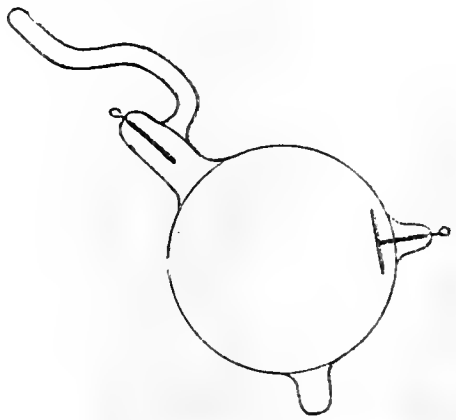

Fig 1.

connected with the source of the current. The bulbs having the terminals sealed in are then very highly exhausted, so that the merest trace of air is left in them, and, when that stage is reached, the glass tube, by which exhaustion was effected, is sealed up. Such tubes in many designs are now upon the market, and in figs. 1 and 2 we give two of those found up to the present to be the most successful in practice. Fig. 1 is a radiant-matter tube designed by Crookes for quite a different purpose, it has been used with the greatest success by Mr. J. William Gifford in his recent work. Fig. 2 is a pattern specially designed for work on Professor Röntgen's lines, and is that used by Mr. Campbell Swinton, who has found it most satisfactory. This is the shape we should be inclined to recommend unless the form shown in fig. 1 is more readily obtainable.

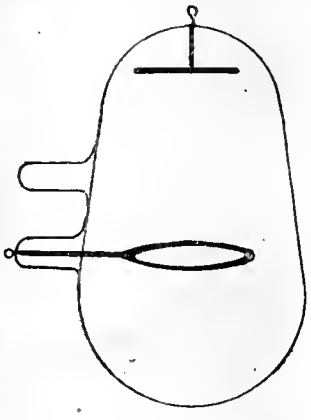

Fig 2.

So much for the tube itself. The source of current is not quite so simple a matter. It can be arranged in several ways, but each arrangement is based on the use of an intensity coil, or, what amounts to the same thing, a transformer. To those accustomed to electrical experiments of one sort and another it is hardly necessary to give more than a word of caution; but, to those who approach these instruments with only a photographic experience, it is only right to point out that a current at the tension at which it is best employed in the tube is by no means a pleasant nor a very safe thing to meddle with. So long as the original source of the current is small in amount, a shock may be merely a very unpleasant experience, but, when the primary source is great, it may not only be unpleasant, but highly dangerous.

To consider the case of batteries, or accumulators, or a small dynamo first, one or other of these sources of supply will be required together with an intensity coil. The batteries may be six or eight pint Bunsen or Grove cells, coupled in series, or their equivalent, while the intensity coil should be capable of giving a four-inch spark. A smaller coil and less battery power will answer if it is merely required to experiment with inanimate objects, coins and the like in purses, &c., and we have little doubt that successful work in this direction could be done with a one-inch spark coil and a couple of Bunsen cells, but the exposure necessary with so small and feeble an apparatus would preclude any very successful work with such things as the hands or feet of living persons, &c.

An intensity coil such as we have spoken of, giving, say, a four-inch spark, is an expensive instrument, and must be handled with care. Particular attention must be given to see that the primary source of current is not greater than is recommended by the maker of the coil, and that the insulation of the coil is not broken down by any means. A defect in this respect, which is almost invisible to the naked eye, would ruin the most expensive coil in a moment.

Essentially, the intensity coil consists of (1) a "core," which takes the form usually of a bundle of straight iron wires, (2) a "primary," consisting of a few coils of comparatively thick copper wire, insulated with silk, and wound round the core, (3) a "secondary," which is wound on the top of the primary, and is composed of a large number of turns of very fine copper wire highly insulated. There is no metallic connexion between the primary and secondary wires in any way, and, while a steady current is passing through the primary, nothing material takes place as regards the secondary. But if the current in the primary wire is rapidly stopped and started again by the circuit being rapidly made and broken, or if it is a fluctuating or alternating current, each variation in the current in the primary wire "induces" a corresponding current in the secondary wire, *but with this difference*, whereas the current in the primary wire may be large in amount, or in "quantity," but low in "tension" or "voltage," that which it induces in the secondary will be small in quantity but high in voltage; very roughly speaking, the tension increases in proportion to the length and number of turns in the secondary. In consequence of this quality, these intensity coils or transformers are largely used where very high-tension electricity is required, or where, having an alternating current at one tension, one is wanted at a different tension. Intensity coils and transformers are identical in principle, the differences being mainly in their details and design. Speaking generally, intensity coils, being made for use with the constant currents from batteries, &c., have to be provided with a "contact breaker," an automatic apparatus for making and breaking the primary circuit, which is indispensable in such cases. Transformers, on the other hand, being made for use with primary currents which are already alternating, require no such apparatus; in most cases also, transformers are made to transform the voltage within much narrower limits than intensity coils. For example, an intensity coil might very easily give a potential of many thousands of volts with a primary current of eight or ten volts, whereas most transformers are made to transform from, say, fifty to a thousand volts, or *vice versâ*.

We have felt bound to make this short and necessarily imperfect explanation at this point for the benefit of our non-technical readers, but the whole matter is one which can only be properly dealt with at a very much greater length, and which will well repay the study of any one of scientific tastes.

To return to our subject, the arrangement of coil, tube, and plate can be gathered from fig 3. The batteries, the carbon of one being connected to the zinc of the next, and so on, are joined by a couple of wires, seen coming into the figure on the left, to the two terminals of the primary of the coil, while by means of two other wires, which may be much thinner, the secondary terminals (A) are connected with the radiant matter tube (B). The hand to be photographed is seen at C, placed upon a dark slide holding the plate. The contact breaker on the coil, as soon as the connexion with the batteries is made, begins to hum; and if all is going well the tube will appear dark inside, but the glass will glow with a greenish light. The secondary terminals of the coil, and the

wires leading from them must on no account be touched while the coil is in operation, or a nasty and dangerous shock will be experienced; nor should the hand be brought too near the secondary wires or connexions, or a spark will pass and a slight shock be experienced, which, while not in any way dangerous to the person receiving it, will make him start, and, in so doing, damage may be done to the delicate tubes or other apparatus near. The primary wire is comparatively harmless.

The tube is best suspended over a table by means of a retort or table stand, which is preferably of wood, and the table itself used as a support for the plate and objects to be depicted. The sketch shows the arrange-

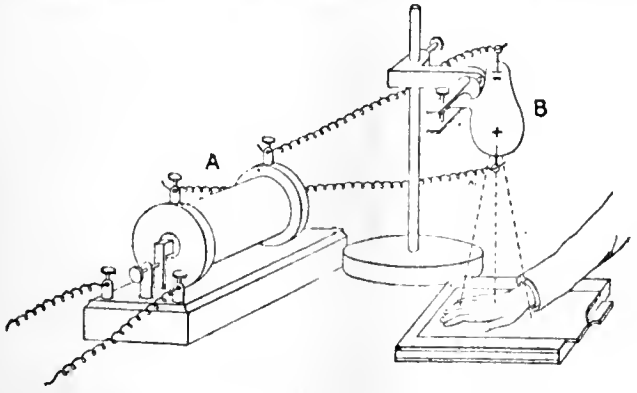

FIG. 3.

ment for making a shadow picture of a hand. A rapid dry plate is protected by having its film in contact with a piece of the fine tissue or waxed paper used in packing plates, and is then enclosed in a couple of black paper envelopes so as to be quite safe from light. If preferred, it may merely be wrapped in three or four folds of opsque paper, or enclosed in an ordinary dark slide with an ebonite, fibre, or wooden shutter. The paper-wrapper method is the best, because it allows the object to be much nearer the plate than when a dark slide is employed, and the shadow is sharper and more true to size. The plate, however protected, is laid on the table at c, in the sketch, film uppermost, the hand, or other object, placed flat upon it, and the current allowed to pass through the primary.

One or two trials should be made with a view to seeing which terminal of the two should be connected with the zinc, and which with the carbon; but this can soon be ascertained by changing them over once or twice; some coils are fitted with a commutator for the purpose. In one position the brightest part of the tube will be the curved bottom next the hand, and this is the one in which the top terminal is said to be the cathode, and should be the one selected. During the exposure the tube glows, as we said before, with a greenish light, and a sound like a miniature hail-storm is emitted from its interior. If the coil is at all powerful, and indeed for safety's sake under any circumstances, the current should not be kept on for more than a half minute at a time, after which an interval of at least half a minute should be given before again making the connexion. If this is not done, there is a great risk of breaking down the tube and utterly spoiling it, and, as they are both expensive and difficult to come by, this is not a course to be recommended.

During use, the glass of the tube gets quite hot, and after running for a little while the tube becomes "fatigued," and is almost useless until it has had a rest of some hours' duration.

We have hitherto spoken of an intensity coil and batteries, but we have seen another arrangement in use which consisted of two transformers, one specially made for very high-tension currents and a battery of Leyden jars. As such an arrangement, however, could only be fitted up by a practical electrician, and depends for its supply of current on an alternating supply from the street mains, and as any meddling with such a supply might lead to dangerous and fatal accidents, we do no more than mention it.

A third method of exciting a radiant-matter tube is by means of a Wimshurst or similar electric machine. There should not be much difficulty in doing this, it being necessary merely to separate the dischargers of the machine sufficiently far apart to prevent their sparking from one to the other and to connect their two knobs by thin wires to the terminals of the tube. It is doubtful whether such an arrangement would be of much use in experiments with living persons on account of the comparative feebleness of the effects, but with other objects it will be probably the most convenient, as it certainly is the cheapest and most compact arrangement of the three.

The photographic details call for very little remark. The developer used should be vigorous and clean in working, the exposure must be largely a matter of guesswork and so care must be used in developing to get all out that can be got. Intensification in most cases can be resorted to with advantage.

The exposure can only be gauged with the greatest difficulty, because the regular working of an intensity coil is very hard to ensure, and because the unexplained phenomenon of "fatigue" in the tube renders each exposure less effective than its predecessor. The tubes, moreover, differ very largely among each other. Some give excellent results, some have little or no effect whatever on the photographic plate, although to the eye no difference in their behaviour with the current was visible.

We have given above the practical details as far as they have at present been determined, and shall supplement them from time to time as occasion may arise. We think it only right to point out, however, that it is most essential that the experimenter using the coil, batteries, &c. should have a certain amount of acquaintance with their construction and use, more in fact than it is possible to give in the pages of a photographic paper. To such we would advise the purchase of a little shilling book issued by Messrs. Perken, Son, & Rayment entitled "Intensity coils, how made and how used," which will be found to give just the information necessary, in a lucid manner and free from technicalities.

We have spoken throughout of an electric current as passing through the tube, and in one or two other ways have used expressions which answered our purpose of explaining the *modus operandi*, but to which exception might be taken on more theoretical grounds; for this we make no apology.

The Inquirer.

*** *In this column we shall, from time to time, print questions that may be addressed to individual contributors to our pages, or such as are sent to us with the view of eliciting information from a variety of sources. We invite the co-operation of our readers in rendering this feature of the* JOURNAL *useful and instructive.*

STAMP CAMERAS (To F. H.)—Messrs. WELLS & Co., of Southgate, write: "Seeing an inquiry in last week's JOURNAL, *re* Stamp Cameras, we beg to state we are agents for Hyatt's patent ditto (and other specialities). This camera is made for taking postage stamps from a cabinet photograph."

LANTERN SLIDES FOR TEACHING PHOTOGRAPHY.—Mr. C. H. BENNET, of 5, Richmond-terrace, Green-lane, Seaforth, writes: "I should be glad to know if it is possible for me to get the use of a few slides to give a somewhat primary description of the art of Photography. I have only a limited knowledge, and I want to try and arrange a paper with limelight views on the subject, to bring before a class of young people connected with a 'Mutual Improvement Society,' with a view of, if possible, starting an 'Amateur Photographic Society,' and, at the same time, to make it as entertaining and interesting as possible."—Perhaps some reader can supply the desired information.

FILMS OF PURE SILVER BROMIDE.—A. W. S., referring to the description of Professor Schumann's methods of preparing films of pure bromide of silver for experimental purposes, considers them unnecessarily troublesome for an admittedly imperfect result. He asks: "Why not employ a Daguerreotype plate, sensitised with the fumes of bromide alone, instead of the usual mixture of iodine and bromide? Such a film, if properly prepared, can be relied upon as consisting of perfectly pure bromide of silver unmixed with any binding material and adhere with all requisite firmness to the plate. It can be developed by the usual aqueous solutions instead of mercurial vapour, and the result, though of no use for printing purposes, would seem to satisfy all the requirements of the experimentalist when a pure bromide of silver film is the object." He goes on further to suggest, in lieu of the Daguerreotype plate, where such is not readily procurable and is probably in some respects superior to it, a very thin film of silver deposited upon glass by any of the usual methods and subsequently converted into bromide. This he considers would have the advantage, if converted throughout its whole thickness, of being free from any possible secondary action, chemical or otherwise, that might arise from the contact of the underlying film of metal in the case of the Daguerreotype plate, and the layer of bromide could be of any desired thinness or the reverse. He would be glad of the opinions of any of our readers who may have had experience in that direction.

ARTIGUE PAPER (To MR. MASKELL).—W. BENINGTON says: "I read with very great interest Mr. Maskell's article on the Artigue pigment process, which I have carefully followed since his interesting demonstration of it at the Photographic Salon two years ago, and would like to ask him one or two questions, if I may so far trespass on your space and his kindness. 1. Is the pigment employed preferably in solution or in the form of powder? 2. What colours are most suitable in such matters as permanence, &c.? and under what names should one ask for them in purchasing, so as to ensure getting the right thing? 3. What is the 'requisite thickness?' and about how much of the bichromate solution is necessary when using (for example) a black? I should like to work out these little matters myself, but unfortunately my time and accommodation, for even these experiments, are very limited."

PANORAMIC PICTURES.—"LAKELAND" would like to have the advice of any of our readers who may have had any experience in the production of panoramic pictures with an ordinary lens and camera. He says: "In the course of my wanderings with the camera I occasionally, but very rarely, come across a subject that is suitable for rendering as a panorama, or that will bear much more than the ordinary angle of view. But, even were I the possessor of a pantascopic camera or similar apparatus, I should not care to carry it about with me on the chance of using it once in three months, for, like the Yankee's 'shooting iron,' I should not want to use it oftener, though, when I did, I might, like him, 'want it bad.' But I know there are various ways of improvising panoramic pictures by joining separate prints, and also, I fancy, by making two or more exposures with a very short-focus lens on a large plate. What I want to arrive at is, which are the best or easiest methods of effecting the junction of the pictures; and which, if any, gives the most correct result as regards perspective?"—Perhaps some of the readers of this column can satisfy our correspondent.

Our Editorial Table.

CATALOGUES RECEIVED.

FROM A. H. Baird, 37 and 39, Lothian-street, Edinburgh: price-list of chemicals for photographic and experimental purposes. From Messrs. Ross & Co., 111, New Bond-street, W.: three neatly printed little booklets, descriptive of Ross-Goerz anastigmatic lenses; the convertible anastigmats; opera glasses, telescopes, &c.

A SECOND edition of *Photo-ceramics*, by W. Ethelbert Henry and H. Snowden Ward, has just been issued by Messrs. Dawbarn & Ward. It is a useful little book, the instructions and formulæ given for the process having been compiled with commendable care.

THE GEM DRY PLATES.

THE youngest of the dry-plate making houses, the Gem Dry Plate Company of Willesden-green, N.W., have recently sent us samples of the plates they are manufacturing—the "Meteor" and the "Special Portrait." The former plate is of very great rapidity and both it and the "Special Portrait," which is adapted for studio use, possess undeniably good technical qualities. We had occasion to write in favourable terms of the "Gem" plates last year, and, judging by the latest samples of them we have tried, the Company should, this season, be successful in their bid for favour. It may be accepted as axiomatic that there is always room on the market for a good dry plate.

INTENSITY COILS: HOW MADE AND HOW USED.

By "DYER." London: Perken, Son, & Rayment, Hatton-garden.

THE recent direct association of electricity, through Röntgen's X ray experiments with photography, may render this little book of service to many would-be followers in the German professor's footsteps. The elements of electrical science are plainly set forth, and chapters are devoted to batteries and their construction; how an intensity coil is made and how used; vacuum experiments, &c. The price of the book, which is in its seventeenth edition, is 1*s*.

News and Notes.

THE *Microscope* gives this formula for an ink for writing on glass with a pen as with ordinary ink: Bleached shellac, 10 parts; Venice turpentine, 5 parts; lamp-black, 5 parts. Dissolve the shellac with turpentine and stir in lamp-black.

BIRMINGHAM PHOTOGRAPHIC SOCIETY.—A very successful *conversazione* was held on Tuesday, February 18, at the Grosvenor Rooms, Grand Hotel. Mr. Alfred Gregory's band provided music for dancing. About 200 members and friends were present.

THE PHOTOGRAPHIC CLUB.—The next weekly meeting of the Club will be held in the Club-room at Anderton's Hotel, Fleet-street, E.C., at eight o'clock on Wednesday evening, March 4. A lecture on the *Photo-chromoscope System of Colour Reproduction*, with lantern illustrations, by Mr. F. E. Ives. The electric power by Messrs. Peto & Radford, of Hatton-garden. Visitors will be welcomed by the members.

EVEN LETTERS ARE NOT PRIVATE.—By means of the new system, two Paris journalists have photographed the contents of a letter through the envelope in which it was enclosed. It appears that every kind of paper is not equally favourable for the operation. Nevertheless (says the *Standard*), the thick Parliamentary envelopes of the Senate and Chamber cannot conceal the secrets which may be contained within. To prevent the cathodic rays penetrating, it suffices to wrap the letter in a sheet of tinfoil, such as is used by the chocolate-makers.

TRULY the appetite grows on what it feeds. A week or two ago a photograph of the bones of a living being's hand, taken through the flesh, would have been considered sensational enough for most people, and G. W. Wilson & Co. (Ltd.) thought they were doing well in publishing Dr. Mackenzie Davidson's "shadowgrams" of hands and feet showing the skeleton. This, however, is not enough for some people, for they have received a telegram from the principal stationer in a large town in the south of England to this effect: "Photographs received very tame; send more sensational ones, such as interior of belly, backbone, brains, liver, kidneys, heart, lungs, soul!!!"—*Aberdeen Evening Express.*

THE Battersea Polytechnic held its third annual *Conversazione* on Saturday evening last to commemorate the opening of the Institute by H.R.H. the Prince of Wales, and over 1500 persons took advantage of the occasion to view the Institute and to participate in the numerous entertainments. One of the chief attractions was the Photographic Exhibition, organized by the newly formed Camera Club. Besides a large number of excellent photographs contributed by the members of the Club, Messrs. Ross, Watson & Sons, Benetfink & Co., exhibited cameras and other photographic and scientific apparatus, and the Eastman Company and Perken & Rayment sent some fine enlargements. An additional attraction was given to the Exhibition by some beautiful statuary, lent for the occasion by Mr. Horace Montford and Messrs. Farmer & Bindley, the latter firm also exhibiting some splendid specimens of ornamental stone. The room in which the Exhibition was held was gaily decorated with plants, and the effect was most pleasing and artistic. The members of the Club are to be congratulated on the success which attended their first Exhibition.

ON Tuesday, February 24, Dr. Danford Thomas, Coroner, held an inquiry respecting the death of Arthur French St. George, aged thirty-four years, a chemist, lately residing at Cotswold House, Earlswood, Surrey, who was killed by the explosion which occurred at 15, Red Lion-square, Holborn, on Thursday, February 20. Mr. Alfred Spencer appeared for the London County Council. Mr. Alfred James De Hailes, analytical chemist, stated that the premises, 15, Red Lion-square, were in his occupation. He knew the deceased, who was bringing out a patent for the manufacture of candles, and a week ago witness let him have the use of his laboratory. Deceased had one small room, and on Thursday last he was demonstrating his patent, and for that purpose used a small cylinder. The cylinder was guaranteed to stand one and a half tons' pressure, but if it was full, and was then placed on a combustion stove, nothing else but an explosion could result. Dr. W. R. Gould, 11, Lamb's Conduit-street, deposed that the top of the deceased's head and the brain had been blown into an adjoining room, fifteen feet from where the body lay. The cylinder was jammed into the ceiling, and in witness's opinion deceased must have been bending his head over it when the explosion occurred. The inquiry was adjourned pending the receipt of the Home Office inspection report.

ACETYLENE A POISONOUS ILLUMINANT.—"Twice in the course of my studies," says Dr. Birchmore, "the opportunity occurred to measure the amount that, diffused in the air of the room, would produce distinct headache in the course of a short time, and it was found to be rather unexpectedly large as compared with the product of the imperfect combustion of the ordinary illuminating gases. As stated, the air in the room wherein the experiments were conducted was known to be changed once in an hour. The cubic contents of the room was about five thousand feet, if a proper allowance is made for the space occupied by properties. The amount of gas diffused was two and a half cubic feet, or one in 10,000. Within twenty minutes a decided headache was noticed, with a sense of dizziness, that was a sufficient warning to get into fresh air. The second time, the experiment was made of remaining until the sight was slightly affected. This proved very foolish, for, in the course of an hour after leaving the room, respiratory difficulty appeared, and, in the course of a few hours, nausea, and a prostration and sense of the impossibility of exertion that forced me to remain in bed all the next day. The effects were not those of sleep, but the exact counterparts of the subjective effects of the ether narcosis—hallucination and all. Three days afterwards the heart respiration ratio was so sensitive that an attempt to walk rapidly across the Brooklyn bridge produced such a feeling of exhaustion as to compel rest."—*Electric Engineer (U.S.).*

DURHAM CITY CAMERA CLUB'S EXHIBITION.—The following were the Judges' awards:—Open Classes. Class I. (Landscapes and Seascapes), silver medal, Wm. Norrie, Fraserburgh; bronze medal, Paul Martin, Wandsworth; certificate, J. H. Gear, London. Class II. (Portraiture and Figure Study), silver medal, F. H. Flather, Scarborough; bronze medal, E. J. Farnaworth, Albany, N.Y.; special bronze medal, F. Marsh, Henley-on-Thames; certificate, R. E. Ruddock, Newcastle. Class III. (Architecture and any Subject), silver medal, H. W. Bennett, London; bronze medal, H. Sandland, Maidstone; certificate, Dr. Stainthorpe, Saltburn-by-the-Sea. Class IV. (Lantern Slides),

silver medal, J. Ward, Erdington; bronze medal, J. H. Gear, London; certificate, Dr. Stainthorpe, Saltburn-by-the-Sea. Members' Classes. Class A (Landscapes and Seascapes), medal, E. White; certificate, J. G. Stokoe. Class B (Portraiture and Figure Study), medal, J. N. Hunter; certificate, D. W. Findlay. Class C (Architecture), medal, E. White. Class D (Club Outings), medal, R. Hanxwell. Class E (Hand-camera Work), medal, H. Oliver; certificate, J. F. Hobson. Class F (One Enlargement), medal, D. W. Findlay; certificate, J. Morson, jun. Class G (Four Lantern Slides), medal, W. Moult; certificate, R. H. Blyth. Special Prizes.—Gold challenge medal, E. White; silver medal, F. W. Cluff; bronze medal, J. G. Stokoe.

SHEFFIELD OPTICAL LANTERN SOCIETY.—This Society held its annual *Conversazione* on the 13th inst., and its annual meeting on the 20th. The large hall in which the *conversazione* was held was crowded by ardent devotees of science, who accorded a hearty welcome to the President (Dr. Manton), who, in his address, gave a brief review of the present position of the photographic world. He pointed out that the quality of the gelatine dry plate was steadily improving, whilst the methods for orthochromatic photography had placed an additional truth in the hands of the photographer. He also spoke of the advent of the new Jena optical glass, and made reference to the New Photography, his concluding remarks being that the scientific world was rapidly reaching the stage at which the supernatural was the natural. The Secretary (Mr. J. Maclaurin) read his annual report, which gave many interesting details of the progress of the Society, incidentally noting the increase of twenty-five members during the past year. The awards in the several competitions were then presented, the successful competitors being Messrs. S. Hughes, A. Nicholson, H. J. Clague, J. H. Lygo, and C. H. Lea. The Judges were: Prints, Mr. Slater, Liverpool; Slides, Mr. Chadwick, Manchester. These prints and slides, together with a large number of others, mostly the work of members, were on view. Some of the latest photographic apparatus and novelties were shown by Messrs. J. Christie and F. Motteshaw. Mr. Henry Staniforth was the Lanternist, and some sensational evidences of photographic skill and ingenuity were thrown upon the screen. The musical programme was effectively rendered by Messrs. Cunningham, Shipman, Reynolds, and Law. At the annual meeting on the 20th, the accounts were audited and passed, showing a balance in hand of 4*l.* 3*s.* 5*d.* Votes of thanks were accorded the retiring officers, and the following elected for the ensuing year:—*President:* Dr. Manton.—*Vice-Presidents:* Alderman Carter and Messrs. J. Clowes and A. Nicholson.—*Reporter:* Mr. J. S. Stephens.—*Treasurer:* Mr. E. Copley.—*Secretary:* Mr. R. Glenn, 107, Nottingham-street.—*Assistant Secretary:* Mr. T. G. Allen, and a Committee consisting of nine members.

Patent News.

THE following applications for Patents were made between February 12 and February 19, 1896:—

CAMERA AND DARK SLIDE.—No. 2965. "An Improved Photographic Camera and Dark Slide." T. P. BETHELL.

PHOTOGRAPHIC MOUNTS.—No. 3026. "Producing the Appearance of Finished Mounted Photographs upon Plain Cards to which Photographic Prints have been Transferred, thus Dispensing with the Ordinary Mounts now in Commercial Use." Complete Specification. J. BACON.

HAND CAMERAS.—No. 3055. "Improvements in and relating to Hand Cameras." A. C. JACKSON.

FLASHLIGHT.—No. 3204. "A New or Improved Apparatus for Producing Flashlight in giving Photographic Exposures." Complete Specification. T. MALONI.

DEVELOPING.—No. 3404. "Improvements in Devices for Oscillating the Baths or Tanks used for Photographic and other Purposes." C. MESSAZ.

HAND CAMERA.—No. 3471. "Photographer Hand Camera." E. C. STANLEY and W. DARBIN.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK

March.	Name of Society.	Subject.
2	North Middlesex	Informal Meeting.
2	Richmond	Lantern Evening: Members' Slides.
2-7	South London	Annual Exhibition.
2	Walthamstow	Slides by Members of the G.E.R. Photographic Society.
3	Brixton and Clapham	Slides by W. H. Whittard.
3	Dulwich	*Toning.* H. S. Jackson.
3	Gospel Oak	Exhibition.
3	Hackney	Lantern Evening: Royal Chapels, &c.
3	North Surrey	*Lantern-slide Making by Contact and Reduction.* T. Bright.
4	Borough Polytechnic	Slides by *Tit Bits.*
4	Croydon Camera Club	*An Introduction to Photo-micrography.* James Packham, F.R.H.S.
4	Edinburgh Photo. Society	*Photography and Art.* G. Baldwin Brown, M.A.
4	Photographic Club	*Photo-chromoscope System of Colour Reproduction.* F. E. Ives.
5	Bradford	Prize Slides.
5	Ealing	Lantern Evening.
5	Leeds Photo. Society	*More Chemicals Used in Photography.* B. A. Burrell, F.I.C.
5	Liverpool Amateur	Lantern in Use.
5	London and Provincial	*The New Photography. Notes and Examples by Various Workers.* H. Snowden Ward.
6	Croydon Camera Club	A Visit to Brin's Oxygen Works.
6	Moseley and District	Lantern and Musical Evening.
7	Birkenhead Photo. Asso.	*Photo-ceramics.* The Secretary.

ROYAL PHOTOGRAPHIC SOCIETY.

FEBRUARY 25,—Technical Meeting,—Mr. J. W. Swan, M.A., F.R.S., in the chair.

The HON. SECRETARY (Mr. Chapman Jones) announced that the Council had elected the following officers: Hon. Secretary, Mr. Chapman Jones; Hon. Librarian, Mr. E. Clifton; Hon. Solicitor, Mr. F. Iuce; and also, to fill vacancies created by those appointments, as a Vice-President, Mr. J. W. Swan, M.A., F.R.S.; and as members of the Council, Messrs. J. W. Marchant and E. Cecil Hertslet. Messrs. Mackie, Pringle, and Warnerke had been re-appointed as Affiliation delegates, and the Chester Photographic Society had been admitted to the Affiliation.

Mr. F. E. IVES exhibited

THE STEREOSCOPIC PHOTOCHROMOSCOPE.

A full description of the apparatus was given in THE BRITISH JOURNAL OF PHOTOGRAPHY for January 17 last, page 39.

Mr. T. E. FRESHWATER, F.R.M.S., then read a paper describing Messrs. Newton's simple method of

STEREOSCOPIC LANTERN PROJECTION,

and showed a series of examples. The process in question is described in our issue of January 10 last, page 24.

Mr. J. CADETT thought it very desirable that the use of coloured spectacles for viewing the pictures should be got rid of, and suggested the use of prismatic spectacles instead.

Mr. T. BOLAS said prismatic spectacles for combining the two images had been used from the earliest days of stereoscopic projection. Sutton employed them in or about the year 1855, and M. Moessard had lately introduced a new form of the same instrument.

The CHAIRMAN recalled Mr. Anderton's method of showing stereoscopic pictures with polarised light; and

Mr. BOLAS said that not only did Mr. Anderton's system permit the exhibition of coloured slides, but M. Ducos du Hauron had succeed in projecting on the screen, according to the three-colour process, two elements of the three-colour system being superimposed for one stereogram, and the third element for the second stereogram, and had by those means obtained coloured effects.

Mr. W. ENGLAND remarked that a great deal of light was lost by the use of deeply tinted glasses in the spectacles and in the lantern, and asked whether it was necessary to have such strong colours.

Mr. IVES said that one of chief reasons why this method of projection had not become popular was that the mixture of coloured effects on the screen was distressing to the eyes, and no satisfaction could be obtained by the observer without the use of the coloured spectacles. It must be remembered that the nerves of one colour-sensation were excited in one eye and the nerves of two other colour-sensations in the other eye, and this was very fatiguing if continued for any length of time. It was possible to project two almost perfectly white pictures on the screen, and to examine them through glasses which appeared to the eye to be smoke-coloured, each picture exciting all the nerves of colour-vision almost equally. This could be done by means of screens of aniline dyes, one to transmit a mixture of spectrum red and spectrum blue-green, and the other a mixture of yellow and violet-blue.

Mr. W. E. DEBENHAM suggested that the fatigue of the eyes caused by the excitation of the same nerves of colour-sensation might be obviated by from time to time altering the order of projection so that the red and green eye-pieces might be brought to either eye alternately, the exhibitor calling out "right" or "left" to indicate the manner in which the spectacles should be used.

Mr. FRESHWATER, in replying, acknowledged that the continued use of the spectacles was tiring to the eyes, but said it was not intended that the system should be employed for an entertainment of an hour or two in duration, but only as an interesting alternation to the ordinary method of projection. He did not think it was possible to use glasses of a lighter colour, as it was necessary that the red glass should entirely shut off the green image, and *vice versâ*. Mr. Debenham's suggestion, he was afraid, was not practicable, for the shouting of "right" and "left" would afford amusement to an audience, and rather interfere with the appreciation of the result.

Mr. J. LUNT, B.Sc., F.C.S., then exhibited a number of slides from

STELLAR PHOTOGRAPHS,

taken without a driving clock. He said his method of working was as follows: A two-and-a-quarter-inch telescope was fixed side by side with one of three and a quarter inches; the image of a star on the two-and-a-quarter-inch was put largely out of focus, producing a disc instead of a point of light; this disc was brought across the cross wires of the two-and-a-quarter-inch instrument, and the pair of telescopes was then slowly moved by hand, so that the cross wires divided the disc into four equal quadrants, the problem being to keep the quadrants equal throughout the time of exposure. This, he had found, was not difficult; and, if the mounting was good and firm, and properly adjusted, so that the star was followed equatorially, the method appeared to be capable of general application to ordinary small telescopes, and very satisfactory photographs could be obtained. Mr. Lunt also showed photographs of the spectra of helium and argon.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

FEBRUARY 20,—Mr. E. J. Wall in the chair.

Messrs. G. E. Segall and E. T. Wright were elected members of the Association.

THE NEW PHOTOGRAPHY.

Mr. T. E. FRESHWATER said he had been making some experiments in the new photography with X rays, using only a very low current. With a low sparking coil, a much more prolonged exposure was necessary than with a high power, but he had succeeded in taking some pictures, which he passed round.

REMOVING STAINS FROM P.O.P.

Mr. W. E. DEBENHAM, although he considered that we ought not to get

yellow stains on printing-out paper now, knew that occasionally it was the case, and then more often than not in a batch. He therefore proposed to show a method of removing the stain, two being selected from a number he passed round. The procedure was as follows:—A print was put in a dish, with just enough water to cover it, and, after soaking a while, a pad of cotton-wool, wetted and rubbed on a cake of cyanide of potassium, was gently passed over the face of the print. He said the action seemed to be more rapid on the stain than on the image, and therefore there was no fear of spoiling the print.

The HON. SECRETARY suggested that the use of a stronger solution might probably improve a vignette.

CONSTRUCTION OF LENSES.

The following question from the box was read: "What is the practical method for calculating the curves requisite in a combination of Jena glass for a given focus?"

The CHAIRMAN mentioned Offord's book for amateurs, from which, he thought, one could get some given curves by which experimental work could be done; also Monckhoven's *Optics*, which, however, did not treat of the Jena glass.

The HON. SECRETARY said three methods were in use—the experimental, the graphic method, and by pure mathematics.

THE KINETIC LANTERN.

Mr. BIRT ACRES, who had promised a display of his new kinetic lantern, apologised for its non-appearance, and explained his reasons for not showing the same. He had but just heard of a competitor from the other side of the Channel who had that day shown his apparatus in London, and he was not satisfied to show to the London and Provincial his original apparatus and take second place. He had machines in the hands of the best London mechanics, but unfortunately they were slow, and he was unable to show his latest improvements. He invited all present to a private view in Piccadilly-circus, where he intended to exhibit his machine, and said a few words about kinetoscopic work. The first practical attempt was made by Mr. Friese Greene, but he had never seen his work. Mr. Acres had been at work on the subject many years, and nearly thirty years ago had made drawings for the zoetrope. When he took up photography, he had an idea to make photographs and then drawing from them. At the London Convention, Mr. Muybridge exhibited pictures showing motion. He believed they were made pretty much on the same plan as he originally proposed of making photographs and then drawings. His first attempts were to put twelve small lenses together, and endeavour in that way to get a succession of pictures, but they were not satisfactory. If you wish to get the best results, the pictures must all be taken from the same point of view. He thought the greatest difficulty was the spacing of the pictures. In a French apparatus they successfully made pictures, but signally failed over the spacing, and that was the main difficulty. It is also of the utmost importance that the photographs should register exactly. Another difficulty he mentioned was with the celluloid films. When making negatives as he did, 200 feet long, one wanted a perfectly ductile film. He had discovered a method by which celluloid films can be made as nice as a piece of silk, and offered to return any film sent him in such a condition.

The CHAIRMAN had seen Lumière's Exhibition, but was of opinion that they were not by any means ready. They had used an electric lamp, with alternating current, and a peculiar disagreeable flicker was apparent. He mentioned that three years ago Edison's results were announced as coming out, but he had not seen anything of them. A worker whom Mr. Acres had omitted to mention was Anschutz, who does not actually project on a screen, but uses an aperture in a wall, while the audience sit in a room at the back, the pictures passing rapidly in front of the opening.

Mr. DEBENHAM asked in what respect the mechanical details differed from Friese Green's machine, and whether the same instrument was used by Lumière for showing and taking the series.

Mr. ACRES referred Mr. Debenham to his patent specification, and said it was absolutely necessary that similar apparatus should be used for taking and projecting. He said that Anschutz's principle was almost the same as one he had discarded as useless.

The CHAIRMAN inquired the respective exposures given to the film and to the positive on the screen.

Mr. ACRES considered it of the utmost importance that the pictures should be taken at the same speed as they were shown, and explained the effect obtained by taking at forty per second and projecting at fifteen per second, and *vice versâ*. He had found an exposure of from one-thousandth to an eight-hundredth of a second quite enough for anything. In the case of a man throwing his hat to the ground, he had counted fifteen negatives. In reply to a query from Mr. Bayston as to the duration of exposure of his longest series, Mr. Birt Acres said he had perfect control over his machine, and could stop and go on as he pleased.

Mr. SNOWDEN WARD, in the interest of historical accuracy, said that the Anschutz instrument was adopted for lantern projection, and was on view at the Chicago World's Fair. With regard also to Edison's work, he said his instrument had been running for some months in several places.

The CHAIRMAN had noticed a defect with Lumière's machine, in which flashes of bright light had appeared.

Mr. ACRES considered they were due to clear spaces in the film, where, by some mechanical defect, the gelatine had been scraped away.

A NEW LENS.

The Hon. Secretary showed one of the most recent developments in lens-making. It was one of the new convertible anastigmats by Ross. It consisted of a double combination, each being composed of four cemented elements. The focus of the front lens was eleven and a half inches, and the back lens nine inches, while combined the focus was five and three-quarter inches. It worked at an aperture of *f*-7.

The CHAIRMAN had tested it for three-colour work, when it is essential that the images should be absolutely of the same size, and found it answered perfectly, and possessed more covering power than almost any in the market. He promised a chat on *Colour*, and to show a few three-colour slides at an early date.

PHOTOGRAPHIC CLUB.

FEBRUARY 19.—Mr. Alexander Cowan in the chair.

Mr. Frank Haes showed a pair of

HARRISON'S GLOBE LENSES,

bearing the name of Vogel, of Philadelphia. The lenses had been the property of the late Robert Slingsby, of Lincoln. The lenses worked at a maximum aperture of about *f*-12. The objection to this form of lens was stated to be a liability to flare spot, but this might be altered or minimised by reducing or increasing the distance between the component parts of the combination.

A general discussion upon the matter of lenses brought up the subject of the newer forms of

ZEISS OBJECTIVES,

and Mr. BRIDGE asked why the visual brightness of the image formed by a Zeiss lens upon the focussing screen was not noticeable in the negatives made with the lenses.

Mr. FINDLAY, a visitor, suggested that it was due to the fact that the Zeiss lenses were corrected for all the rays of the spectrum so far as chromatic aberration is concerned. This would make the visual image appear brighter.

Mr. BULBECK said that he had found these lenses quite apochromatic, and Mr. FRY added that, owing to the fact that equally good definition could be obtained with a considerably larger aperture, it was possible to make good work under less advantageous conditions of light, the necessity for stopping down not obtaining. He added that such lenses could be used with a condenser and artificial light more satisfactorily than could the older forms of rectilinear lenses.

Mr. B. J. EDWARDS then interested the meeting with a description and demonstration of his new

CAMERA FOR THREE-COLOUR WORK.

Mr. Edwards touched briefly upon the subject of the generally accepted theory of colour vision, viz., that there are three colour sensations—red, green, and blue-violet. He makes his three negatives—one for the red sensation, reaching a little higher than D in the spectrum; the second for the green, reaching as far as E; and the third for the blue-violet—all at one exposure, by means of an ingeniously arranged camera, containing two lightly silvered mirrors. The first mirror—that nearest the lens—reflects the rays upon the plate which is to receive the red, the plate being specially colour-sensitised, and protected by a suitable red-colour screen or light filter. A part of the light from the lens passes through the first mirror towards the second, which again reflects a part of it to a second sensitive plate, specially coloured, sensitised, and protected by a green light filter. The remainder of the light passes through the second mirror, and falls upon a third plate, which is colour-sensitised for the blue-violet rays, and is similarly protected by a light filter of suitable colour and character. By this contrivance Mr. Edwards stated that he, in one operation, made his three separate negatives, the positives from which, properly combined and viewed through suitably coloured media, result in a photochromoscopic picture. Mr. Edwards also stated that his instrument can be used as a viewing apparatus for combining the positives. This he showed in practice with one of his own experimental pictures of a vase of flowers. The result appeared charmingly natural and realistic, and demonstrated that the apparatus promises to be of a most useful and practical character.

In reply to questions Mr. EDWARDS stated that he used a Zeiss-Satz lens of seven-inch focus on the recommendation of Dr. Rudolph, and he found the correction for colour and aberrations exceedingly satisfactory. The three negatives must be developed at one time and to one depth. He preferred the method of using plates each separately sensitised for its own colour. A plate sensitised for all colours was not so suitable for his method. In development care must be taken to use as little light as possible, and that of the right sort. A dark red orange combined with green was the most suitable. In reply to Mr. Cowan it was said that the positives must be printed to the same depth, but that certain liberties could be taken in this part of the process, as the luminosity as well as the colour of the light used for viewing the resulting pictures controlled and influenced the effects obtained. Mr. Edwards said his two greatest difficulties had been with the lenses and with the mirrors: with the former to get all the images of the same size and equally defined; with the latter to deposit the silver of suitable density and colour.

Mr. Edwards's invention appeared to consist mainly of a camera for taking the "colour" negatives at one and the same time by one exposure, and the use of partially silvered mirrors, so as to avoid double reflections and residual images. The camera could be used alternatively as a viewing machine or for optical projection.

Brixton and Clapham Camera Club.—February 18, Mr. J. W. Coade (President) in the chair.—A demonstration on

STEREOSCOPIC PHOTOGRAPHY

was given by Mr. J. GUNSTON. In his introduction Mr. Gunston said he did not intend to enter far into theory or to explain why it is that by looking in the glasses of the stereoscope we see two objects as one, and why, by looking too frequently in other glasses, some persons see one object as two or more. He left it for those who had made these phenomena their special study, but had brought with him a little apparatus and some specimens, and hoped to explain by example what he did not by precept. Stereoscopic photography was, in his opinion, one of the most satisfactory and interesting branches of our hobby. A paper stereograph was good, but a good stereoscopic transparency was one of the most beautiful objects photography can give us. Seeing the picture in relief enables one to form a far better idea of a place than from a single picture, and it is a common thing to hear people explain, after looking at a stereoscopic picture, "They could almost believe they were there!" A good series of stereoscopic views will delight people of all ages and of all degrees of culture, as no special attainment is required to appreciate them, all that is needed being a good stereoscope, which can now be obtained at a ridiculously low sum. Any sized camera, from $6\frac{1}{2} \times 3\frac{1}{2}$ to whole-plate, is suitable. The square pattern should be chosen, and not the kind with tapering bellows. He used a Watson's $7\frac{1}{2} \times 5$ inch Premier as a rule, and had

also brought with him a very neat instrument, the Alpha stereoscopic hand camera, by the same makers. Chadwick, of Manchester, could also be relied upon for stereoscopic apparatus. Perhaps double quarter-plate ($6\frac{1}{2} \times 4\frac{1}{4}$) is the most convenient-sized plate to use. The camera must be fitted with a central division, which will expand with the opening of the bellows, and the lenses must be paired, *i.e.*, they must be of exactly identical focal lengths, and work at precisely the same aperture—requirements which cannot be met unless the lenses have been made especially for stereoscopic purposes. Their focal lengths may vary from three to seven inches, five-inch lenses being best for average work. To save expense, single lenses may be used, and answer well for everything except for particular architectural work, as, although distortion may be evident in the prints, it is not noticed when the same are viewed through the stereoscoper. The lenses must be mounted side by side at exactly the same height from the camera baseboard, and their distance apart may vary from two and a half to three and a quarter inches, the shorter separation being suitable for distant objects, and *vice versâ*. It is convenient to mount them on movable centres; the distance between them may be then changed as wanted, three inches being most generally useful. The lenses must also be fitted with a shutter which will give an equal and simultaneous uncovering to each lens. In choosing the subjects suited for stereographs, take care to have some prominent object in the foreground, which is a most important part of the picture, panoramic views without near objects being almost useless. The focussing *must* be sharp, anything in the way of "fuzzy-types" being intolerable. Backed plates are to be preferred, and full exposure should be given, as foggy, flat, and over-exposed negatives, although useless for anything else, often make prints that look well through the stereoscope, while chalky, dense, under-exposed negatives are useless. The negatives should be free from mechanical defects, as scratches, &c. In printing from the negatives, use a glossy paper. Collodio-chloride is good; matt or rough-surfaced papers are no use. In trimming the prints, see you have a base line common to both. They should be about two and three quarter inches wide, and have about the same distance between the centres of the foreground, taking care to beware of too wide a distance apart. A special cutting shape, as supplied by Chadwick, here comes in useful. The prints must have a separation of about one-eighth of an inch on the mount, which is best of a chocolate colour. When viewed through the stereoscope, a dark mount seems to stand out in relief in front of the picture, thus giving the effect of looking at the same through an open window.

Camera Club.—February 20.—Mr. CHAPMAN JONES addressed the Camera Club on the subject of measuring

THE DENSITY OF NEGATIVES,

introducing to the notice of the members the apparatus which he has himself constructed for this purpose, a description of which has already appeared in these pages. He remarked that the terms "density" and "speed" were too much confounded with one another, although they were essentially different in meaning. Every photographer judges of his negative by its density, and will hold it up in the developing dish, or, at a later stage, to the window, in order to gain some idea of its merits in this respect. Such an examination may be regarded as unscientific, but it will often give all the information necessary. The man who sells lollipops does not need a chemical balance, nor does a carpenter require a micrometer measure, and there is, in like manner, much to be said in favour of this cursory inspection of negatives. The ordinary ear can distinguish the pitch of one note from another, while the highly trained musician can recognise any note by its pitch, and can name it; and it is quite possible that, with practice, a man of keen perception would be enabled to correctly judge, by simple inspection, of the density value of any plate submitted to him. He would need no measuring instrument, and could determine, approximately, which of two squares was the denser. Messrs. Hurter & Driffield had stated that the density of a negative could not be varied by the time occupied in development; but this he considered was contrary to general experience. Inspection, as he had said, gives all information in most cases, but certain precautions should be observed. All parts of the plate not under examination should be covered, say, by paper with a hole cut over the part to be observed. By this means very small differences of density could be detected, especially if a white screen be held behind the negative to reflect the light through it. In cases where differences of densities were very slight, or where the deposit was very thin, it would be convenient to place the negative flat down upon and touching a sheet of white paper. It was, of course, an advantage to have the compared parts near together, but, where this was impossible, one could look through each separately at surrounding objects, and thus ascertain which constituted the stronger veil. Mr. Chapman Jones then described the method of judging density adopted by Captain Abney, and that advocated by Messrs. Hurter & Driffield. In his own instrument he had followed Captain Abney's procedure, but had made certain modifications in the method, which he described. His own apparatus was home-made, and he could point to many details where it could be improved. He showed on the screen a tabular statement of the results obtained by measuring certain plates, and he was able to show how nearly they corresponded with the results obtained from the same plates by Captain Abney. They differed somewhat from the measurements given by Messrs. Hurter & Driffield's system, as might have been expected, for reasons which he had already indicated.

Dulwich Photographic Society.—February 18.—Several members gave an exhibition of their lantern-slide making. Mr. H. J. Ellis must be congratulated on his up-the-river scenes, Teddington, Chertsey, &c., and also a few views of Dulwich village and park; while Mr. Jackson and Mr. G. E. Smith exhibited pictures on various subjects. The Hon. Secretary was also complimented on his work, especially a river scene, Abindon-on-Thames, a scene from the Avenue of Trees at Tooting Common, and a group of the Junior Section of the well-known St. James's Swimming Club standing on the diving boards at the Dulwich Baths. The next meeting of the Society will take place on Tuesday, March 3, at 8.30 p.m., when a demonstration on *Toning* will be given by Mr. H. S. Jackson, assisted by the Hon. Secretary.

East London Photographic Society.—February 11, Mr. W. B. Gould presiding.—A demonstration on the

CARBON PROCESS

was given by the Autotype Company. The permanency of the results by this method, combined with the great variety of colours it was possible to select from, were two of its many recommendations. Unlike the silver process, no visible change was apparent during the operation of printing, the exposure having to be gauged by an actinometer, several kinds being shown and explained. Sensitised tissue would keep about fourteen days. For reproducing crayon drawings it was *par excellence*, giving almost facsimile copies. In the single transfer, many grains and tints of paper could be used. With the rough paper supports, much longer time should elapse between squeegeeing and developing, so as to admit of the tissue sinking well into the interstices of the paper; neglect of this point would probably result in blisters. An hour or more was advised. A large number of prints—single and double transfer—were developed, and turned out highly successful. Many large works, completely finished, were hung around the room, and were voted charming specimens of the process.

Hackney Photographic Society.—February 18, Mr. R. Beckett presiding.—Mr. A. Dean showed a negative of the shadows of interwoven strips of gold, silver, aluminium, and platinum foils, produced by the rays from a Crookes' tube through a one-inch thickness of vulcanite. Specimens of work done on the Beerneart lantern plates were shown. Mr. Roberts showed some negatives covered with peculiar markings, which had appeared during development. The plates, after exposure, had been packed in pairs face to face and placed in negative envelopes. Mr. HERBERT FRY thought that, by mistake, the plates in question had been packed with their films touching the material of the envelope, and the fibre of the paper being, possibly, slightly damp, had caused the markings to show on developing. The best way to pack plates after exposure was, undoubtedly, to place them face to face with nothing between, after seeing beforehand that the films were free from dust. They should then be packed tightly to prevent abrasion. Mr. Fry then showed McKellen's Infallible hand camera. This is of the magazine type, and is constructed to hold twelve plates or twenty-four films in sheaths. The method of changing is very ingenious, and among the advantages claimed the most important are that the changing of the plate does not depend on the instrument being held in a particular way, but acts in any position; again, when changed, the plates are held firmly, and are not loose as in some other cameras. The camera is made in various grades from quarter-plate size to half-plate. It has the usual accessories, and is furnished with a safety shutter behind the lens, which automatically closes, the latter when the camera front is opened.

Bootle Photographic Society.—February 18.—Mr. NAHUM LUBOSHEZ, of the Eastman Company gave a lecture on

PORTRAITURE AND PLATINO-BROMIDE PAPERS.

The lecturer explained that these papers were so called on account of the similarity of surface, coating, and results obtainable, there being no salt of platinum present in the emulsion from which they are prepared. Some magnificent specimens were exhibited, and the process of toning the paper shown, considerable astonishment being caused by seeing the paper stand immersion for some minutes in a bath not far from boiling point, the ability to stand this treatment being due to the fact that the image is on the surface of the paper, and not, as ordinarily, embedded in a film of gelatine.

Bournemouth Photographic Society.—February 19.—A lecture and demonstration of the

NEW PHOTOGRAPHY,

illustrated with photographs taken during the evening, and others thrown on the screen from Mr. C. Dale's lantern, were given by Mr. J. W. GIFFORD, F.R.P.S., F.R.M.S., F.S.A., of Chard. Dr. HYLA GREVES (the Vice-President of the Bournemouth Photographic Society), in introducing the lecturer, made humorous reference to the results which might ensue from the discovery. Mr. Gifford has spent a good deal of time lately in his laboratory making experiments with a view to finding out the best medium through which the "invisible rays" might be focussed. With a view to ascertain if the Crookes' radiant tube, used for the new photography, would be improved by an aluminium window, he placed an aluminium plate and a glass plate, gauged to the same thickness on the film operated on. The obstruction to light was almost equal. An ebonite doublet lens and an aluminium doublet, mounted each in a brass tube, was placed over the film, and the results were *nil*, although a plate of aluminium shows perceptible refraction. The obstruction which aluminium offers to these rays evidently balances any effects of refraction. Some perfect images of discs have been obtained by reflection. Mica and celluloid are extremely transparent to the rays, and will be most useful for protecting the sensitive film from the hand, foot, &c., or other objects, the bones of which are to be photographed. Gold leaf, silver leaf, and Dutch metal leaf were tried. Gold leaf opposed the rays most, then Dutch metal; silver leaf acts as if absent; glass gives decided evidence of refraction, like aluminium, but it is so opaque to the rays that the increasing thickness of a glass lens towards its centre appears entirely to neutralise the perceptible concentration of the rays. Mr. Gifford is aware that this is contrary to the experience of other experimenters, and therefore only advances it with the greatest reserve. Uranium glass placed on the film behaves in every way like ordinary glass. Generally speaking, the sharp definition tube should be placed as far off as possible. In the presence of several medical gentlemen Mr. Gifford photographed the arm and hand of a young lady suffering from disease in the bones of those limbs. The negatives revealed these bones as if entirely denuded of flesh, and the disease could be traced with much ease. A foot was laid before the rays with the same result, even the densest and thickest part of the limb being, as it were, "laid open to view." The lecturer went into a detailed description of most of the above and other experiments, which was listened to with great attention. Several photographs were taken during the evening, and, after development, were exhibited, very successful results being attained.

Bristol and West of England Amateur Photographic Association.—Friday, the 14th inst., at the Literary and Philosophic Club, Mr. G. W. GWYER read an interesting paper on the construction of

LIMELIGHT JETS,

explaining his theory of their correct construction, and demonstrating by experiment that an enormous increase of light was gained by those constructed on the principle which he advocated. He exhibited the jet for which he gained the first award in competition with about twenty others at the meeting of the Photographic Club last month in London, and also showed one possessing still more recent improvements which he had made. The light from the two jets was compared and tested by the photometer, which showed that the improvements approximately doubled the illumination obtained from the jet shown in London, although the nipple used with the improved jet was only one-sixteenth bore against one-twelfth on the other. The results were considered by the meeting to evidence a very great advance in the construction of limelight jets, and a vote of thanks was accorded Mr. Gwyer for his interesting demonstration. A number of lantern slidea were subsequently shown on the screen by the Rev. T. Clark and Messrs. S. J. Hill, W. Moline, Thomas Letchford, and others.

Darwen Photographic Association.—February 11, the Rev. Henry Irving in the chair.—A good assembly of members were present to hear a lecture delivered by Mr. ALFRED READ, of Blackburn, entitled

WANDERINGS WITH A CAMERA,

and, as the lecture was accompanied by slides, nearly all of which were of Mr. Read's own taking, and shown upon the screen by the agency of Mr. George Butterworth's limelight lantern, the audience enjoyed it immensely. Amongst the pictures projected were local and Continental views, comprising a number of glacier scenes, for which Mr. Read is worthy of no little amount of congratulation, as also his snap-shots on the Bowling Green, showing the different amusing attitudes of the bowlers. During the lecture, much interest was taken in the projection of a human hand taken by Professor Röntgen's method. The artistic qualities of the slides prove Mr. Read to be a photographer of no mean order.

FEBRUARY 14.—Mr. NAHUM LUBOSHEZ (representing the Eastman Photographic Materials Company, Limited) delivered a lecture on

A TALK ABOUT SUCCESSFUL PORTRAITURE AND PLATINO-BROMIDE PAPERS,

and at the outset of his remarks the lecturer expressed a wish that those of his audience who failed to accurately grasp his meaning would ask questions, when he would do his best to answer. He first dealt with the question of the paper to be used, and pointed out that the platino-bromide paper was very sensitive. The difference between this class of paper and the ordinary bromide paper was that it gave an absolute photographic image, whilst the others required a certain amount of dodging and retouching to make a finished photograph. The platino-bromide paper is very thinly coated, and this gave the image a clear surface, whilst the other papers, being thickly coated, the image is viewed through the coating itself, as in the case of a negative, the latter being coated with exactly the same emulsion, only that the extra-rapid plates contain more silver, and all plates require a thicker coating. The Eastman Company's platino-bromide paper is about as sensitive as the average ordinary plate. To make a good portrait, there were a few essential conditions, one of which was that there should be absolute whites and pure blacks. When looking on an image of black and white, one would see that the white was nothing more nor less than the paper itself, seen through the photographic coating. The photographer should take care that the whites of the picture are not stained, as the photograph with the least stains upon it would certainly secure the best prize. This was one of the essential points, and a perfect picture would not be the result if a developer was used which had a tendency to stain the paper or attack the delicate coating. The lecturer then proceeded to speak of the methods to be employed in order to get pure blacks, and stated that the developer used in the process had much to do with this. Mr. Luboshez then went on to say that pyro was a developer that when applied was practically colourless, but immediately it came in contact with the paper it changed to a dirty brown, and whatever came in contact with it was stained in the same way. Many different developers were mentioned as being suitable for bromide work—amidol, metol, glycin, ferrous oxalate, and almost all the new developers—but the one to be employed was that which the worker was best able to control, as it was a matter of individual taste. Not only is it necessary that the worker should be able to control the developer, but every step of the work until the image is perfectly finished. The highest possible result can only be produced when each and every step of the work can be controlled, the developer especially so, and not to let oneself be controlled, as the moment they allowed their work to get the upper hand they were at sea. In order to be able to control the developer used there must be time, and some developers do not allow the necessary time. The lecturer enumerated certain developers, pointing out some of the defects, and mentioned, incidentally, that the manufacturer of a developer was once asked by a photographer, who was at the time suffering from skin irritation, caused by using this certain developer, what was the antidote, and the manufacturer replied that he was not aware of any. Mr. Luboshez strongly recommends the ferrous-oxalate developer as being in every way the best for bromide work, for, no matter how long it is kept on the paper, it does not change its condition. One good feature of this developer is that it can be mixed, the different proportions as required; for instance, if an image is wanted strong in the blacks and clear in the whites, the developer may be mixed accordingly. Much good advice was given by Mr. Luboshez on this phase of photography, and amongst other things he warned his audience against doing their work in a mechanical way.

Leeds Camera Club.—February 20.—Mr. H. F. WIGGLESWORTH gave a lecture and demonstration on

ACETYLENE.

Mr. Wigglesworth said that acetylene or "electric gas," as it is sometimes called, is spoken of as a new gas, but it is by no means new, because it has been known to chemists for a large number of years. In 1836 Edmund Davy was aware of its existence, and he at that time called it "klumene." A few years later, Bertholet gave it its present name of acetylene or ethine. Whilst working with an electric furnace, and endeavouring by its aid to form an alloy of calcium from some of its compounds, Mr. T. L. Wilson noticed that a mixture containing lime or chalk and powdered anthracite fused down to a semi-metallic mass under the temperature of the arc, and, when found not to be the substance required, was thrown on one side into a pail of water; but, after a time, the overwhelming odour evolved enforced attention, and, on the application of a light, a luminous but smoky flame was given. Mr. Wilson then turned his attention to this, and found that in a properly constructed electric furnace powdered lime or chalk and carbon could be fused, and the result was the formation of calcium carbide. On the addition of water to this, a double decomposition takes place, the oxygen of the water combines with the calcium and forms oxide of calcium, and the hydrogen unites with the carbon and forms acetylene. The carbide is a dark grey substance, and, on the addition of water to one pound, about five feet of gas is given off. Acetylene is a clear, colourless gas, with a very strong odour resembling garlic. Ordinary burners, through which coal gas is consumed, are useless for showing acetylene to advantage, and it is recommended to use 0000, 00000, or 000000 Bray's burners. The former burns about one and a quarter feet, the next one foot, and the latter two-thirds of a foot per hour. The carbide can be purchased commercially at prices varying from 1*s.* to 5*d.* per pound, and several generators have already been made, but, doubtless, a cheap one will very soon be put on the market, so that it can be used in private houses. If ordinary coal gas costs 2*s.* 4*d.* per 1000 feet (as in Leeds), and calcium carbide 6*d.* per pound, the relative cost of both gases would be, light for light, 2*s.* 4*d.* for coal gas, and 4*s.* 6*d.* for acetylene, so that, if the carbide can be produced and sold at 3*d.* or less per pound, coal gas will have a strong competitor for lighting purposes. Professor Lewes, in a lecture a short time ago, gave the following figures, which require no comment:—

Burner.	Gas consumed.	Carbon dioxide produced.	Adults.
Flat flame burner, No. 6	19·2	10·1	16·8
,, ,, ,, ,, 5	22·9	12·1	20·0
,, ,, ,, ,, 4	25·3	13·4	22·3
Loudon Argand	15·0	7·9	13·1
Acetylene	1·0	2·0	3·6

The last column shows the number of adults who would exhale the same amount of carbon dioxide in the same time. The heat given off from the acetylene gas is very small compared with ordinary coal gas. Acetylene is a very powerful explosive if mixed with twelve or thirteen times its volume of atmosphere. If two or three burners can be arranged in suitable positions, no doubt use can be made of acetylene for lantern work, but for photographic purposes it will doubtless not be of much use, in consequence of the flame not being strong in actinic rays. At the close of the lecture Mr. Wigglesworth showed the gas burning through 00000 burner, and when compared with coal gas it was acknowledged to be far superior in every way.

Liverpool Amateur Photographic Association.—February 20, Mr. Joseph Earp in the chair.—Dr. D. J. W. Ellis, F.E.S., gave a demonstration on

PLATINOTYPE TONING

of gelatino-chloride paper. He described the *modus operandi* in detail, and successfully toned a series of six prints, all from the same negative, to various shades, from warm brown to dark purple.

Moseley and District Photographic Society.—February 21, Captain Davidson (Vice-President) in the chair.—Before an exceedingly large muster (about 150), amongst the number many of the city and local surgeons, Mr. HALL EDWARDS, L.R.C.P., F.R.P.S. (the President) lectured on

RÖNTGEN'S RADIATIONS.

He began by explaining the method in which these rays were produced. Having shown an ordinary vacuum tube, and passing a current of electricity through it, the colours produced were very vivid; but that was not what was known as X rays. These rays were produced in a Crookes' tube, a tube exhausted to a much greater degree. The current he had got at his disposal was not strong enough to give the X rays; but, when they were produced, there was not the light as in an ordinary vacuum tube, but only a slight green light at one end and violet at the other. The lantern was then called into requisition, and slides from Dr. Hall Edwards's negatives were thrown on the sheet. Many and interesting were the slides, and one which the lecturer said was specially interesting, as it showed one of these writing-pencil patent folding pocket compasses, the lead of the pencil coming out slightly, but the cedar wood was quite transparent to the rays. But now, in contradiction to what he had on a previous occasion stated, he thought that nothing was opaque to these X rays. This slide, he said, was an argument in his favour, for, where the metals crossed, there could be distinctly seen the extra density on the screen. The rays would pass through anything if long enough were given. The slide of the lady's hand, wherein was deposited the needle, brought forth applause, for, by the aid of a negative taken by the doctor, the surgeons at the Queen's Hospital were enabled to extract it, although previously having failed to find it; also the hand with the bullet in it called for special applause. The radiograph showed the bullet quite plainly, and the lecturer stated that he gave longer exposure to this hand, as he knew that lead was one of the most impervious substances to these rays. In reference to recent statements about getting images with 3*l.* 3*s.* apparatus, he stated that he did not say it was impossible, but thought that it may possibly be noised abroad by a cheap coil dealer. He would not be now surprised to hear of negatives being taken by means of the scullery house mangle.

Glasgow and West of Scotland Amateur Photographic Association.—February 17.—The Council were empowered to take the preliminary steps for holding an International Photographic Exhibition in Glasgow in 1897. Mr. D. C. Coghill lectured on

PHOTOGRAPHY IN RELATION TO LETTERPRESS PRINTING AND PROCESS ENGRAVING.

He explained, and showed by examples, the many ways in which pho

graphy is employed by printers for purposes of illustration and reproduction. After illustrating the general principles of mechanical engraving by transferring a line drawing to zinc and etching the plate, he described the photographic methods of preparing plates for etching. The requirements of half-tone work were then explained, and a reversing mirror and lined screen were exhibited. Details of the bitumen and enamel processes were given, and blocks by each process were etched and printed successfully. The three-colour process was also described, and fine examples of colour-printing were exhibited. Many hints as to the kind of photograph or drawing best suited for reproduction, the paper for printing, and the care of blocks, were given during the lecture. Mr. Coghill was assisted by a number of his own staff of printers, and by representatives of the Regent Engraving Company.

1896. FORTHCOMING EXHIBITIONS.

February 28, 29..... Woolwich Photographic Society.

COLOUR-RENDERING ON ORDINARY PLATES.

To the EDITORS.

GENTLEMEN,—As I was present at the meeting of the Croydon Camera Club when Mr. White gave his most able paper on *The Photography of Colours*, and having given my experience as corroborative of his own as regards the behaviour of ordinary plates with the yellow screen, in Mr. White's absence I shall be very glad to meet Mr. Wall for a practical defence of the position which I understood Mr. White to take up as regards colour rendering by non-colour-corrected plates. I object to academical discussions at either of the mentioned societies, but suggest the selection of some accessible stained glass window for the practical test with the camera. It must be understood that Mr. White did not contend that prolonged exposure of the plates in question, without a screen or yellow illumination, would alter the rendering of the blues and violets. However, nobody who tries prolonged exposure will find other result than Mr. White, in the better, if not perfect, rendering of the yellows and reds, but he must use the screen to suppress his blues and violets whether he uses colour sensitive or other plates. Thanking you, sir, for your space,—I am, yours, &c., J. T. SANDELL.

The Sandell Works Company Limited, South Norwood, London, S.E., February 24, 1896.

To the EDITORS.

GENTLEMEN,—Mr. Punnett (p. 124) is, no doubt, quite right about the difference between aurine and aurantia. Aurine has been put up for me when I asked for aurantia, and several other dyes have each two or more different trade names. Aniline reds, all practically alike and indistinguishable in the spectroscope, are sold as roseine, fuchsine, magenta, and azaleine. It is unfortunate that some dealers in dyestuffs create confusion by using inexact names for chemical products.

My strictures apply only to the dye which I named in my letter, and not to aurantia, which, if it is something quite different, may very well give quite different results. The dyes which I have named give the results which I have described, and this Mr. Punnett, I am glad to see, now fully admits.—I am, yours, &c., F. E. IVES.

To the EDITORS.

GENTLEMEN,—I have no wish to enter into a controversy with Mr. Punnett, but his comment on my letter (p. 15, January 3) is so very vulgar, that I ask to be allowed a few words in reply.

The object of my letter was to express my keen and sincere appreciation of Mr. Ives's labours to improve our knowledge of orthochromatic photography, and to suggest a more generous recognition of what is due to him; this is not flattery. Mr. Punnett does not know the meaning of the words he uses.

Mr. Punnett, in his first letter (p. 735, November 15), says: "animated by Mr. Ives's article, we made a screen of chrysoidine and deep naphthol yellow, but could not obtain satisfactory results." In his letter this week (p. 124) he quotes fourteen experiments, twelve of which are admittedly valueless. One is the old combination advised by Mr. Ives, which he now describes as yielding almost perfect results; and the last is a combination of his own, which he thinks is equal to the one first recommended by Mr Ives, but with which he failed to get satisfactory results in November last. This means, if it means anything, that he might have accepted Mr. Ives's formula in the first instance, and saved himself the trouble of recording a number of worthless experiments.

The obvious aim of Mr. Punnett's first letter was to confuse the issue by insinuating that Mr. Ives's orthochromatic results on ordinary plates were due to some latent orthochromatic quality in the plates made by a firm in which Mr. Punnett is interested—plates which Mr. Ives admitted using and spoke well of—How very generous! As to the dye, Mr. Punnett is not so accurate as his erudite references would lead one to expect; he did not advocate aurantia in his first letter, but a substance he called aurentia; that being so, is it any wonder some confusion arose as to what substance he really did mean?

It would be presumption on my part to forestall any comments Mr. Ives may wish to make on Mr. Punnett's letter. I have therefore only touched upon those points which possibly come better from an outsider. Certainly Mr. Punnett might with advantage adopt the advice he proffers to me. Advice is cheap—cheap as free advertisements.—I am, yours, &c.,

Roundhay, February 24, 1896. F. H. BUATON.

To the EDITORS.

GENTLEMEN,—Mr. Hector Maclean's letter in your last issue displays an ignorance of facts, and is so full of unwarrantable sneers and innuendoes, both astonishing and unworthy in a man of his position as President of a Society, that I shall let it severely alone.—I am, yours, &c.,

E. J. WALL.

THE KEEPING QUALITIES OF SENSITIVE CARBON TISSUE.

To the EDITORS.

GENTLEMEN,—We see on all sides the increasing popularity of the carbon process amongst all classes of photographers, and this in spite of two great disadvantages which it possesses, namely, the limited keeping qualities of the sensitive tissue, and the necessity of transferring the image, disadvantages which, if effectually removed, would give an enormous impetus to its use. Experimenters have for some time been at work on the latter problem; but, although I have been a fairly constant reader of the photographic press for several years, I do not recollect seeing one paragraph having mention of the former, yet this would certainly be a very useful field for experiment.

We know, of course, that moisture exerts a considerable influence in hastening insolubility, and the idea struck me, as, doubtless, it has others also, of keeping the sensitive tissue in an airtight calcium tube, such as is used in platinotype work, in order to see if damp was the only cause of insolubility. I discovered it was not.

The effect of keeping the tissue in this dry state was naturally to render it exceedingly brittle, so the simple expedient at once suggested itself of softening the pieces required for use by holding them for a minute or so in the steam of a kettle. By adopting this method I was able, at various times up till October 1895, to print transparencies on tissue obtained from the Autotype Company in the end of September 1894, over twelve months.

Again, some standard brown, bearing the date of November 1894, yielded good prints, and was readily soluble up till April 1895; but, towards the end of July, on again trying it, it was found to be insoluble.

It is noteworthy that these two batches, as well as some to be referred to later on, were, as soon as procured, kept together in the same tube, under identical conditions, notwithstanding the difference in the time during which they remained good.

At Midsummer 1895, I obtained four packets of sensitive tissue of different colours—black, brown, sepia, and red chalk—and, not being able to use them at once, I placed them in the calcium tube; but to my surprise, on attempting to develop them in a little over three weeks' time, I found that they were hopelessly insoluble, although the transparency tissue previously mentioned was still perfectly good.

This clearly showed that there was some element of decomposition in the tissue itself, apart from the conditions of storage.

On speaking once to a representative of the Autotype Company, I mentioned the subject, and he stated that, in his experience, the temperature and state of the atmosphere at the time of sensitising the tissue had a great influence on its keeping qualities, some, sensitised in the heat of summer, often being unfit for use in a day or two, whereas it is well known that, if sensitised in cold weather, it may be kept for three weeks or a month without any special precautions.

It is evident, therefore, that, if these unknown factors could be discovered and understood, it might be possible to manufacture a tissue of vastly increased keeping properties.

I trust that this may be the means of eliciting correspondence on the subject, as some amongst your numerous readers must have made similar observations to my own, and perhaps carried them a great deal farther.

Believing that I have suggested a by no means unprofitable direction for investigation,—I am, yours, &c., R. WELLBY.

Sandycombe, Kew Gardens, February 24, 1896.

WATKINS DEVELOPING COMPETITION.

To the EDITORS.

GENTLEMEN,—The Judges' report of the above does not, I fear, give competitors and others much useful information. It is not even stated how the prize-winners attained their results, and those wishing to continue similar trials are given no help from the experience gained in these. The results (except those of Messrs. Edwards) have now come into my hands, and, as I find there is much to be learnt from them, I am drawing up a report of what each competitor has done, and summarising the results.

When I announced this competition, I stated my anticipation that competitors "will be able to show slight changes of gradation (independently of fog and stage of development), but only in certain limited directions." I was wrong as regards the word "slight," for a decided change has been proved, but the few competitors who have shown change of gradation have all done so with the aid of strong (over eight grains to an ounce) pyro developers.—I am, yours, &c., ALFRED WATKINS.

Hereford, February 23, 1896.

PHOTO-CHROMOSCOPES.

To the EDITORS.

GENTLEMEN,—Mr. Edwards (p. 125), referring to my statement (p. 109), that the photo-chromoscope shown by him was "constructed in accordance with my patent specifications, and for the purposes specified therein," and is an "infringement of my patent claims," says I "must know such statements to be incorrect." On the contrary, I know them to be correct. This instrument, as constructed by Mr. Edwards, is my own by priority of invention, publication, and patent; there is nothing in it that had not been fully disclosed before Mr. Edwards' first date of record, and it infringes some of my most important patent claims.

Mr. Edwards says that, had he been content with the use of coloured glass reflectors, he would have patented the device before I did; but I cannot make this statement fit in with other statements, facts, and dates on record. In the first place, he did not need to wait to "conceive the plan of using plain glasses slightly silvered on one surface" (p. 94), any more than to invent the use of coloured glass reflectors, because both of these ideas had been disclosed by me, in a British patent of March 8, 1892, and in a paper read at the Society of Arts, May 17, 1893. But not even an application made immediately after the time when he says he tried coloured glasses (*one only* of the methods specified in my patent), "fully *six* months" before he applied for provisional protection, would have made his patent antedate my own, which was filed nearly *eight* months before his. And, then, his provisional specification does not disclose several important features which were shown and claimed as new in my patent specification filed July 3, 1894, and which do not appear in Mr. Edwards's records until December 19, 1895, four or five months after they were shown in an illustration of my instrument which appeared in at least three London photographic journals.

Mr. Edwards also makes claims with reference to the use of separate and different plates with a single exposure, and triple prints, two elements of which are on separate glasses, and the third on a thin film between them. Both of these ideas were also disclosed by me years ago, with differences of detail only; the first in a lecture at the Franklin Institute, in Philadelphia, December 19, 1890, on which occasion I showed the camera in which I then used three separate and different plates with one exposure; and the second, in my book, "A New Principle in Heliochromy." It is evident that every one of my cameras, single-lens or otherwise, has been adapted to the use of separate and different plates if preferred, and that the principle is no less my own because I have more recently recommended a procedure which I believe to be, on the whole, far better.

It appears, therefore, that Mr. Edwards has been so far behind time with *all* of his ideas, that he has "no standing, either in fact or in law." Other statements which he makes in his letter are not justified by the facts, but an adequate reply would occupy much space, and I hope that it will not be made necessary.

I cannot reply fully to Mons. Nachet until I have seen his patent, which I believe has not yet been published. One statement, however, is untrue, and another is so incomplete as to appear to be calculated to mislead; so that, altogether, Mons. Nachet's communication sounds to me like mere "bluff." I *have* a patent in France, which, under French patent law, protects my invention there from July 3, 1894; and the only claim which Mons. Nachet quotes from his patent of March 29, 1894, is anticipated (as it stands in the quotation) in a French patent granted to me in 1892. What his additional certificates may contain is a matter of no importance as affecting my patent rights.—I am, yours, &c.,

F. E. IVES.

PHOTOGRAPHIC COPYRIGHT.

To the EDITORS.

GENTLEMEN,—Under above heading, in your issue of 21st inst., there appears a letter from Messrs. Patrick & Sons, of Edinburgh. Will you allow me, in the interests of the whole landscape publishing trade, to explain, firstly, the reasons which induced the Committee of the Photographers' Copyright Union to frame Rule 23; and, secondly, to point out what has been the practical result of the rule?

Owing to the enterprise of the editors of the illustrated press, and the wonderful development of all classes of process work, an entirely new and profitable source of income has been opened up to the publisher of landscape photographs. It only gradually dawned on the latter that he was justly and fairly entitled to some compensation for the use of his picture, which had cost him time and money to produce. That was the first stage; then came the time when we all charged whatever seemed good to us, with the result that we under-quoted each other, and generally cut each other's throats all round. Then the Copyright Union took us under its wing, and suggested that we ourselves should fix a minimum fee and stick to it. This we did, fixing the same at 10*s.* 6*d.*, and I shall presently point out how the rule has worked.

In order to complete my case, I must next turn to the users of our copyright pictures, the editors and publishers of the illustrated press. It is here that the best work of the Union has been done, and a result has been accomplished which speaks volumes for the tact and administrative powers of the President and his lieutenants. I have said that the reproduction of landscape photographs in the illustrated press was a new trade for the photographer, and in no less degree it was a new one for the editor. At first the latter did not see why he should pay anything for the use of one of our photographs; he never had done so, and he didn't see why he should begin to do so. Now, no man, single-handed, can either fight or convince an editor, and I have no hesitation in saying that, had it not been for the courteous, but well-armed, front displayed by the Photographers' Copyright Union, a most valuable part of our annual turn-over would have been, in great degree, lost to us. In order to illustrate the working of the rule, I must give my own personal experience, which I imagine to be the average one. During the time my firm have been members of the Union our income from fees has steadily increased, and now amounts to more than a few hundreds a year. A large part of this sum is earned by negatives which only command the minimum fee of 10*s.* 6*d.* As a proof, however, that a really good subject will command a good price, I may mention that during 1894, in some hundreds of cases, we obtained from twice to ten times the minimum sum fixed by the Union. We started with the idea of treating the editor as fairly and honestly as we could, and I am glad to have this opportunity of placing on record my appreciation of the generous and straightforward way in which the illustrated press have met the Photographers' Copyright Union. I may safely say that, in the great majority of cases, both editor and photographer are now agreed that 10*s.* 6*d.* is a fair and reasonable price to pay for the use of the latter's property, and I have never found an editor to refuse a higher sum for a picture of exceptional merit or interest.

I think Messrs. Patrick & Sons will find in the end that Rule 23 is their greatest safeguard and protection, and our own experience has proved, over and over again, that we gain far more than we lose by its observance. In reply to a communication requesting a lower quotation than 10*s.* 6*d.*, a courteous letter, stating that the latter sum is the minimum allowed by the Union, and that, consequently, the writers are unable to give way, will, in most cases, bring about the desired result. Every day membership in the Union is being extended, and every photographer who enlists under its banner strengthens our cause by lessening the danger of unfair competition and underselling.

The result of repealing the rule, or of reducing the minimum fee to simply a nominal amount, would be to cut the ground away from under our feet. Whatever quotation we gave, we should know to a certainty that some one would under-quote us, and, what is now a fine and profitable trade would soon be of no use to any of us. The establishment and loyal observance of the rule as it stands puts us all on a level. By this time the editor of any paper of importance knows as well as we do that the minimum fee is 10*s.* 6*d.* This he is prepared to pay, and his only aim now is to get the best picture he can find. This state of things will only produce a fair and friendly rivalry, and an added anxiety on our part to produce the best possible work; unfair competition and underselling (which have ruined so many kindred trades) will be an impossibility.

Messrs. Patrick & Sons are, of course, right in saying that there are people who will not pay the minimum fee allowed by the Union, and who will use every endeavour to find a cheaper market; but these latter gentlemen will find it more difficult every day to obtain such cheap illustrations. Every photographer who can be persuaded to join our Union takes a man out of the enemy's camp. A man has everything to gain and nothing to lose by becoming a member, and I feel sure the influence of Messrs. Patrick would be sufficient to obtain many new members in their part of the world. These are still the early days of the Union, but, when we see what has been already accomplished by its instrumentality, we are certainly justified in hoping and expecting that the annoying cases referred to by Messrs. Patrick will become daily less frequent.—I am, yours, &c.,

February 25, 1896. E. FRITH

(*F. Frith & Co., Reigate*).

To the EDITORS.

GENTLEMEN,—In your issue of February 14, Mr. Henry Gower defends Rule 23 of the Copyright Union against the criticism of a contemporary, and argues that a rule is made to be observed; that is precisely why many provincial photographers (myself included) are prevented from joining the Union, as we know that we should often be compelled to break that particular rule.

We prefer to remain outside a body, whose general aims have our heartiest approval, rather than make a promise we should not be able to keep.

The position of the provincial photographer is quite different to that of his brother professional in London; no doubt, it would be greatly to the advantage of the latter, and of the publisher of photographs (whose business has, no doubt, suffered severely during the last few years from the competition of cheap reproductions), to persuade every photographer in the country to make a charge for every one of his photographs that is reproduced. But the provincial man knows that his interests, and those of the London photographers, especially those who work largely for publication, are not identical, and he fails to see why he should throw away chances of obtaining work in order to put a lever into the hands of the London publisher of photographs.

There is no doubt that Rule 23 prevents many from joining the Union. I know at least three in Birmingham.—I am, yours, &c.,

HAROLD BAKER, Photographer.

58, *New-street (opposite Colonnade), Birmingham, February*, 18, 1896.

THE RECENT LIMELIGHT COMPETITION.

To the EDITORS.

GENTLEMEN,—Mr. Gwyer has declined my offer to submit our respective jets to independent experts, and has therefore no right to question the verdict given at the public competition on January 22 last.

If he advertises or allows any one else to advertise that "the Gwyer jet proved the best at the jet competition on January 22," he will be circulating a statement which is incorrect.

I am sorry Mr. Gwyer cannot calculate that a diameter of ·085 gives an opening of more than one third larger than ·072, but the fact remains.—I am, yours, &c., W. SCARBOROUGH.

Crouch End, February 22, 1896.

OPERATORS' GRIEVANCES.

To the EDITORS.

GENTLEMEN,—Many number of times have I read in the JOURNAL, with no little interest, "Airings of Photographers' and Photographic Assistants' Grievances;" therefore I shall be glad if you can find a small space for the following:—"Photographers and their Advertisements" I have often wondered why they don't state the wages when advertising for an assistant. I am sure it is quite as easy to do that as to say, "Good wages given." They must know perfectly well the wages they can afford, or better still, they "intend paying." Can any photographer assign any reason for not doing so? Surely, they can't be ashamed to advertise the salary, if it is a fair one; but this is where the photographer's weak point lies.

Another item of importance is the "Keeping of Specimens," but which is not evidently considered so by photographers generally. They usually receive specimens, in answer to their advertisements, on a Saturday morning, and are detained by them *over* the following Saturday, which debars the assistant (unless he has two sets of photographs of himself—and not many have) from answering any situation he may see in that week's JOURNAL. They are not even returned then, unless a second application is made for them. This is gross and selfish neglect on the photographer's part; yet he is the first to cry out about not being able to get an assistant to work for his interests. No wonder, for at present they have a very one-sided way of doing business.—I am, yours, &c., ABOVEBOARD.

February 21, 1896.

AN APPEAL.

To the EDITORS.

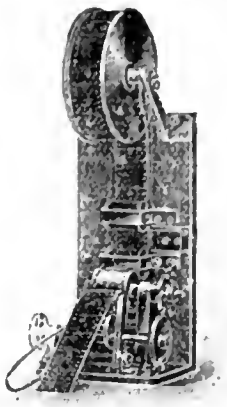
GENTLEMEN,—For over thirty years Mr. William H. Harrison has been engaged in matters connected with photographic progress, and he has beyond doubt materially contributed to that progress. He has been a regular contributor of useful articles to photographic journals, especially THE BRITISH JOURNAL OF PHOTOGRAPHY, and latterly *Photography*. For some time he was editor of the *Photographic News* His nature and manner being singularly unobtrusive, his works were frequently known where his name was unknown.

Among the special subjects investigated and written about by Mr. Harrison have been the following: the methods of preserving wet plates in working order for considerable periods; devices for rendering tourist cameras lighter without loss of efficiency; he was the first to make a gelatine emulsion and to develop it with alkaline pyro; but pressure of other work prevented him from following up his remarkable discovery. (See Mr. Bolas' lecture at the Photographic Society, 1892.) Briefly, during thirty years Mr. Harrison has steadily worked on photographic matters, has materially assisted in progress, and has never tried to make pecuniary gain out of his work. He is now, through no fault of his own, stricken down with brain paralysis, and scientific writing has not enabled him to lay up for old age or illness. We, therefore, with much confidence appeal to the photographic world to assist in this most deserving case. Contributions will be gladly received and acknowledged by F. H. Varley, 82, Newington Green-road, London, N.—We are, yours, &c.

ANDREW PRINGLE, FREDERICK H. VARLEY.

THE THEATROGRAPH.

MR. R. W. PAUL, of 44, Hatton-garden, is the inventor of this piece of apparatus, which is designed for the projection of kinetoscopic pictures on to the lantern screen. It is constructed of steel, gun metal, and aluminium, and of such size as to go between the condenser and objective of an ordinary lantern. The film containing the photographs is drawn from the spool at the top of the instrument, and passes under the rollers and pressure pad in front of an oblong aperture through which the light passes, then under an aluminium sprocket wheel to a second spool, on which it is automatically wound up. Each turn of the horizontal shaft, which is driven from a small hand wheel, actuates a cam, which instantaneously shuts off the light, and at the same time the sprocket wheel is acted on by a steel finger, causing it to move forward the space of one picture; the film is then locked in position for projection, the shutter opens and allows the picture to be projected. In this way the film is at rest the greater part of a revolution, giving a bright image. The rapid revolution of the shaft causes successive pictures to appear without discontinuity, as in the kinetoscope, until the whole scene has been presented.



We witnessed the theatrograph in actual operation, and the projected images, with the lifelike motions of the figures, were successfully shown. If the theatrograph, together with series of kinetoscopic photographs, is available at reasonable prices, it should supply an extremely popular addition to the resources of the lantern lecturer.

Answers to Correspondents.

*** *All matters intended for the text portion of this* JOURNAL, *including queries, must be addressed to* "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 2, *York-street, Covent Garden, London. Inattention to this ensures delay.*

*** *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

*** *Communications relating to Advertisements and general business affairs should be addressed to Messrs.* HENRY GREENWOOD & CO., 2, *York-street, Covent Garden, London.*

"NIKKO," "BOHEMIAN," P. PARSONS, C. C. BATES, "TABLEAUX VIVANTS," and others in our next.

LENSES.—PHOTOIC ART says: "I am about to erect a small studio, about 23×9 feet, with a lean-to roof, 12 feet to 7 feet, to face light N.E. In this it is my desire to make various studies, full-length figures, small groupings, &c. I shall use a 15×12 studio camera, and all sizes of plates down to quarter-plate, and wish for your esteemed advice in choice of lens or lenses for the purpose under above conditions."—The studio is small for the class of work to be done in it. To do all, several lenses will be required. The most useful will be one of the group or universal series of about twenty-four inches focus for the larger sizes; a portrait lens for cabinets, and one for *cartes-de-visite*.

PHOTOGRAPHING IN THE NATIONAL GALLERY.—E. B. says: "Can you inform me whether it is possible for the public to obtain leave to photograph pictures in the National Gallery; and, if so, to whom should application be made? I refer to pictures which could be taken as they hang."—In reply: Write to the Secretary, National Gallery, Trafalgar-square. We believe permission is obtained without much difficulty.

STAINS.—ROYAL STUDIO writes: "We enclose print, and should feel obliged if you could give us the cause of the yellow spots on same. We have had about half a dozen similar. They are of a white, milky colour at first, and afterwards go yellow."—The stains are caused in the fixing solutions, either from the prints sticking together for a time, or air bubbles being allowed to stick to them.

PERISHED INDIARUBBER.—SHUTTER says: "About eighteen months ago I bought a new shutter with pneumatic release. Soon after the ball began to collapse, and now is quite flat. Unscrewing the ball does not tend to fill it, and, if forced into shape, only collapses again when the pressure is removed. The rubber is quite thick enough to keep it in shape."—Evidently the rubber has perished. You will have to get a new ball.

TONING DIFFICULTY.—P. F. L. S. writes: "I shall be much obliged if you will tell me the cause of the enclosed prints toning to such a nasty colour in their half-tones. They are on Eastman's Solio paper, which has been in stock only a few days, and has been carefully kept in a tin box. The toning bath used was given by Eastman."—The toning bath is clearly out of order. Better make a new one and keep it a day or two before using it.

TONING.—HYPO asks: "Will you kindly tell me what is the cause of the P.O.P. prints going a muddy colour? We tone 100, and two or three go muddy and a few go pinky. We use the Ilford paper. We use hard water, not distilled. Is that the cause of it?"—As only two or three out of 100 toned in the same bath are unsatisfactory, it is clear that the manipulation is at fault. The two prints enclosed are decidedly over-toned, the only fault with them.

PRICE-LISTS.—RAE writes as under: "I am about to issue a twelve-page catalogue of enlargements, specialities, &c., and, having been troubled before by other people copying my prices, in fact, issuing a facsimile price-list, altering name and address only, I should be glad if you will tell me in your next issue if I can copyright a new one at Stationers' Hall?"—Prices cannot be made copyright, so that others cannot charge the same; therefore it would be of no use registering the new catalogue.

CRACKED FILMS.—JAS. PATERSON says: "Can you tell me any reason for the cracking of the film on the enclosed plate? The collodion is Mawson's, six weeks iodised, and the albumen substratum is very strong. I suspect the varnish, and would be glad of a remedy if you can oblige me."—It looks very much as if the varnish had been the cause of the trouble, or it may be the substratum, if that were too thick. We should advise the trial of another brand of varnish and a thinner substratum, or none at all. By abandoning the substratum the varnish has the chance of penetrating to the glass, and, as it were, binding to it.

TRAIN IN MOTION.—ARTHUR R. REILLY. "Allow me to ask you the following questions. What stop, lens, light, plate (how many times wet) would I require to take a train running twelve miles an hour? What would be the exposure?"—Before answering such a question as this, we should require to know the sensitiveness of the wet plate. Wet plates, according to the state of the bath, collodion, &c., vary greatly in their sensibility. However, it may be roughly stated that, to take an object sharp, broadside on, moving at twelve miles an hour, the exposure must be about the three-hundredth of a second, supposing the object to be fifty or sixty feet from the camera. From this may be judged the plate and aperture of the lens to use.

ELEMENTARY BOOKS.—"WANT TO LEARN" says: "I should be much obliged if you would advise me as to what books (elementary) I ought to get on the following subjects: Light, Optics, and Photographic Chemistry. I have advanced books on the above subjects, but find they are too technical for me to understand at present, as I am entirely ignorant of the subjects, and am much puzzled by the mysterious signs, symbols, &c., which are not explained. As I take an interest in these subjects, and should like to study them, I should feel much obliged for your advice."—In reply: *Light*, by Sir H. Trueman Wood; *Photographic Lenses*, by J. A. Hodges; *Materia Photographica*, by C. J. Leaper. Your photographic dealer will procure them for you.

RESIDUES.—RESIDUE asks: "Would you kindly answer the following questions:—1. Have the ashes from either gelatino-chloride, 'or sensitised papers on a nitrate bath,' to be treated in any way before putting into the furnace to run down the silver? 2. The best way to recover the silver from an old sensitising bath, so as to run down in the furnace? 3. I presume chloride of silver will melt in the furnace? 4. Could you give me the name of any book that would help me on the above subject?"—1 and 3. The residues will require flux. This is equal parts of the carbonates of soda and of potash; one and a half parts of the mixture to one part of the residue. 2. Add common salt, and the silver will be precipitated as chloride. 4. No. Plenty on the subject will be found in back volumes of the JOURNAL.

LIGHTING OF PORTRAITS.—CADE. Several of the portraits would be better if they had had less front and top light; they would have had greater rotundity, which they lack, particularly the profiles. The studio is an unsuitable one.

PRIZES, MAGNESIUM LAMP, LUNAR PHOTOGRAPH, STOPS.—F. KING says: "May I ask you to kindly answer the following? 1. Do Messrs. Faulkner intend giving prizes annually for photographs? 2. A description of the modern magnesium wire or ribbon-burning apparatus, without clockwork? 3. How may a picture of the moon be taken with an ordinary telescope? 4. What is the difference between the ordinary and the universal system of stop-marking? Will a stop one-eighth of the principal focus be *f*·8 by the universal system?"—In reply: 1. We do not know. Better write the firm. 2. There are several forms. Better call at a dealer's and see the different sorts. 3. Fit a camera on the eyepiece end of the instrument, and mount it with the usual clockwork arrangement to follow the motion. 4. Yes.

BUILDING LAW.—STUDIO writes: "There are two houses together; we occupy one of them, and we have a large garden each, which are thirty-six feet from front of house. Our garden is 36 × 29 feet, which gives me ample room for a studio 24 × 16 feet. 1. Can any one prevent me from building one? 2. Shall I have to pay anything? 3. Is there any particular way or means of building it so as I shall not have to pay anything? 4. If I build it with wheels on, could the City Council object? The garden is walled and palisades all round, and it would not interfere with any one."—In reply: 1. Impossible to answer the question, as we do not know the bylaws of the particular city. Each town makes its own. 2 and 3. If it is not against the law, no, except, perhaps, a fee to the local surveyor. 4. We imagine that building the studio on wheels will make no difference—as regards the City Council.

ACETYLENE.—Referring to Mr. G. H. Rodwell's communication recently, and replying for other correspondents, we may say that Mr. Banks and Mr. Rodwell are practically correct in their estimate of the volume of acetylene gas obtainable from one pound of calcium carbide. We have repeated the calculations hurriedly made in replying to E. W. B. the previous week, and find that, owing to the misplacement of the decimal point in the figures in a table of specific gravities to which we referred, we arrived at a very much higher result than the correct one. On going over our calculations again, however, and taking the specific gravity of acetylene as 0·92, with air as unity, the volume of the gas theoretically obtainable from one pound of the carbide lies between the figures given by Mr. Banks and Mr. Rodwell, and, allowing for impurities, the former is, no doubt, practically correct.

INTENSIFYING PROCESS.—B. F. G. asks if the bromide-of-copper intensifier is considered a good process for intensifying gelatine negatives, as he has tried it on some that were extremely thin, and altogether failed, as it "seems to intensify the shadows more than the rest of the picture."—In reply: That method of intensification, we should say, is eminently unsuited for use with gelatine plates of any kind, but more especially for half-tone subjects. The amount of density it gives is far too great for any but black-and-white or process negatives, while the difficulty of removing the last trace of the copper solution from the film previous to the application of the silver solution, and subsequently the removal of the latter, militate much against its use if it were otherwise allowable. But most probably our correspondent's chief cause of failure lies in imperfect removal of the hypo from the film before bleaching, for, even with a collodion plate fixed in hypo, it is in the last degree difficult to sufficiently get rid of the latter salt.

COLLODIO-CHLORIDE FOR TRANSPARENCIES.—W. HODSON writes: "I have made some collodio-chloride emulsion by a formula that I used to succeed with very well some years ago for small portrait work, but I now want to use it for transparencies. When employed for this purpose, although it gives a rich, vigorous image, I find great difficulty both in getting a coating free from irregularities and also in keeping the film on the plate. The film, when dried by heat, appears at first perfectly uniform, but soon becomes studded over with crystals and markings, many of which show badly in the finished picture. Can you suggest any means of avoiding this, and can you say if it would be of any use to employ a substratum of any kind to prevent the film slipping, and, if so, what? It seems to me that this would be a ready way of making reversed negatives by the nitric-acid process if the physical difficulties could be overcome."—In reply: A series of articles will be found in our volume for 1891 on *Collodio-chloride for Transparencies*, in which the difficulties mentioned are dealt with; but, if our correspondent cannot refer to those articles, we may say briefly that the irregularities are due to the large proportion of soluble and crystallisable matter contained in the emulsion, which, in the case of paper prints, are absorbed by the paper; but, when glass is used, as they cannot sink into the support, they crystallise in and on the film, producing the result complained of. To obtain the best results on glass a special emulsion should be used; but, even with an ordinary emulsion, the defects may be greatly ameliorated, or almost annihilated, by using a substratum of gelatine, rendered partially insoluble with chrome alum. This forms a porous layer, into which the salts are in great measure absorbed, as in the case of paper, while, at the same time, it helps to hold the collodion film on the glass. With regard to the adaptation of the "print-out" emulsion to the nitric-acid reversal process, we fear you will not find it answer, for the reason that the image formed by the direct action of light is not soluble in nitric acid, and is therefore not removable by that means in the same way as a developed image.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 1870. Vol. XLIII.—MARCH 6, 1896.

Contents.

EX CATHEDRÂ.

Very many of our readers, we are sure, will learn with regret that Mr. W. H. Harrison, who for about a quarter of a century was a valued contributor to these pages, has been stricken down with paralysis of the brain, and is thus rendered unable to follow any occupation.

* * *

An appeal on his behalf is made by Messrs. Andrew Pringle and F. H. Varley, whose letter we published last week. Mr. Harrison's best years and energies have been spent in the study of photography, in the journalism of which he has ever taken a part as prominent as it was honourable, and we hope that a prompt response will be given to the appeal that has been made on his behalf. Mr. F. H. Varley, 82 Newington Green-road, Highbury, will receive subscriptions, or they may be forwarded to us.

* * *

The Corporation of Glasgow have determined to inaugurate the new Camphill Gallery with a Photographic Exhibition. The undertaking will be carried out by the Museum and Galleries Committee, aided by a Consulting Committee, which is in process of formation. The Exhibition will be held from the early part of June till the end of September, and will comprise:—(1) Illustrations of the History of Photography: Early Daguerrotypes, Calotypes, &c. (2) Photographic Instruments, Materials, and Appliances, Lenses, Cameras, Chemicals, &c. (3) Illustrations of Modern Processes in Photography. (4) Applications of Photography: Portraiture, landscape photographs, architecture; reproductions of pictures, drawings, etchings, and engravings; photo-lithographs, photogravures, phototypy, photo-block-printing; colour photography; Röntgen's photographs; copying plans, maps, mechanical drawings; illustration of books; lantern slides; decoration of glass, pottery, vitrified enamels, &c.; astronomy, meteorology, microscopy, spectroscopy, &c.

* * *

The preliminary prospectus states that the object of the Exhibition is to illustrate the history and development of photography, and to show the numerous and important applications of the art to science, art, and industry. The elements of competition and trade will not enter into the Exhibition, nor will there be any prize offered to exhibitors. Portraits will be shown only in so far as they may serve to illustrate the various methods of portrait photography, or special features of size, treatment, artistic excellence, &c. Landscapes may be accepted on account of the interest of the subject, as well as for technical excellence. Reproductions of art objects will be received both as illustrations of processes and for the artistic interest and importance they possess. No charge will be made to contributors. Communications respecting the business of the Exhibition are to be addressed to the Secretary, at the Corporation Galleries of Art, 270, Sauchiehall-street, Glasgow.

* * *

Messrs. Thomas Illingworth & Co., the well-known photographic printers and enlargers, of Willesden, inform us that they have opened west-end showrooms at 5, Soho-street, Oxford-street, W., where they intend keeping the latest novelties suitable for photographers, and a display of enlargements, &c. The central position of the new showrooms will, no doubt, prove a convenience to the firm's London clients.

* * *

Mr. Hugh Clements, of 61, Barry-road, S.E., has been good enough to forward us a copy of his weather predictions for the month of March. The subject is one to which he has devoted

special study, and last year he began the publication of a monthly journal called *The Clerk of the Weather*, the predictions in which, we noted at the time, were signally accurate. We append Mr. Clements' March predictions; they apply to the London district only.

* * *

"My predictions," says Mr. Clements, "so far this year have been correct in almost every detail. *Rainfall:* There will be under the average rainfall, and, on the whole, March will be a fine and rather dry month. The most unsettled part will be from the 6th to the 14th. There will be also some slight unsettlement at the commencement of the month, the 20th, 22nd, and 29th, the weather being generally fair from 15th to 31st, and from 2nd to 6th. *Temperature:* Generally the first half of the month will be milder and the latter half colder. The milder days will occur on 1st, 6th to 11th, and from 21st to 24th, and the colder days will be from 2nd to 5th, 14th to 20th, 25th to 27th, and 29th to 31st. The minimum temperature will scarcely go below 25°, nor appreciably exceed 40°, while the maximum temperature will probably seldom exceed 55° nor descend under 35°. *Winds:* There will be strong winds, storms, or gales round our coast on or about the 3rd, 7th or 8th, 11th to 13th, and from 21st to 24th. *Air-pressure:* The barometer will be higher on or about the 4th, 7th or 8th, 10th or 11th, 16th to 21st, and 30th and 31st, and lower at the beginning of the month, and on the 6th, 9th, 13th, 22nd, 25th, or 26th."

* * *

"These predictions," adds Mr. Clements, "are made for London because the metropolis is the only place in England for which I can obtain the necessary records of the past weather. Even if there were satisfactory records for other parts of England, and even places abroad, it would be impossible to give a forecast of the weather that would be correct for several places at the same time, as the weather at any given moment differs for different places, but it is possible to give correct predictions for each separate place, provided the necessary records for each of these separate places are available. The weather at any given moment differs at different parts of the earth's surface, but at that moment it is exactly the same for each different place as it was at a previous moment when the lunar cycles were exactly the same."

* * *

Messrs. George Houghton & Sons, of 89, High Holborn, W.C., are supplying the whole of the apparatus necessary for electrographic experiments, including Crookes' tubes, bichromate batteries, and Ruhmkorff induction coils.

THE RÖNTGEN RAYS.

From every part of the civilised globe, from universities, physical laboratories, public colleges, we might almost say from village schools, accounts come pouring in to the scientific and newspaper press, and to learned and other societies, till they cannot keep pace with them, of further experiments with the Röntgen rays, or other unknown invisible radiations. Though there has been an apparent tendency to show that the new rays are not new, that they are merely further manifestations of Lenard rays, the consensus of skilled opinion all goes to show that Röntgen truly deserves the title of discoverer, and that the Paris Academy were doing him justice in linking his name with the new force, whose results he had described. It is further evident that his first announcement gave lucid and exact accounts of a thoroughly reasoned-out series of logically connected experiments, which the majority of experimenters have, so far, merely repeated with variations, and verified. Images on photographic plates, films, and papers have been obtained through light-opaque screens by the radiations from Wimshurst machines, ordinary vacuum tubes excited by coils large and small, the brush from a Ruhmkorff's coil, Crookes' tubes, rendered active by Ruhmkorff's coils, with and without a Tesla coil added, and actuated by battery, electricity from the main of both high and low intensity, or from a statical machine; also without any electrical machine at all, merely by the light from a paraffin lamp, or by daylight; and, finally, and this appears almost a *reductio ad absurdum*, with no sensible radiations whatever, merely by placing a plate against a negative in total darkness. Yet evidence is slowly accumulating that Röntgen rays are unique, novel, and wonderful, hence the most important scientific aspect of the discovery is the question what are they—electricity, magnetism, light, or a new form of energy? Mr. Crookes' remarks upon Professor Röntgen's refusal to accept the hypotheses which identify the X rays with either the ultra-red, the visible, the ultra-violet rays (such as have been hitherto studied), or the Lenard rays, are as cogent as could be uttered: "Perhaps the best way to ascertain the nature of the X rays will be to work with them." There is no doubt that, owing to the great popularity of the practice of amateur photography, an immense amount of working with the rays is being done, but comparatively little of it in the manner Mr. Crookes intends.

One confusing result is found in the fact that contrary conclusions have been arrived at by different observers working at the same set of experiments. As an example, we may say that, while Röntgen and others found glass to be not very permeable to the rays, Mr. Gifford* suggests "that glass is fairly transparent to the Röntgen rays; almost as transparent as aluminium, in fact."

As to the relative transparency of substances, M. V. Chaubaud† found it mainly a question of degree. Aluminium had already been shown to be very transparent. Lead, zinc, copper, zinc amalgam, tin, steel, gold, and silver were not opaque with a thickness of ·2 mm., but platinum was, though at a thickness of ·01 mm. it was easily permeable. Mercury at a thickness of ·1 mm. was quite opaque. M. M. Meslans‡ submitted proofs to the Academy referring to about fifty substances from which he was able to draw certain general conclusions. The organic substances, ethers, acids, and nitrogenous substances were easily traversed; but the introduction into the organic molecule of a mineral element, iodine, chlorine, fluorine, phosphorus, &c., gives to the molecule a great opacity. The opacity of bones is due to their mineral constituents. At present, indeed, the relative transparency and opacity just alluded to seems to him to be established as a general law. MM. Launelongue & Oudin§ claim to be the first who have taken negatives of the thigh and knee. Professor Wertheimer‖ finds bones not wholly opaque, and describes an experiment in which a needle on the under portion of the distal end of the first phalanx of the great toe gave a distinct sciograph, thus showing the bone to be partially transparent.

* Quoted in *Nature*, vol. liii. p. 380.
† *Comptes Rendus*, cxii. p. 237. ‡ *Ibid.*, p. 309.
§ *Ibid.*, p. 283. ‖ Quoted in *Nature*, vol. liii. p. 379.

With regard to the sensitiveness of the plate and its influence, M. Albert Londe* finds the impression much more energetic on rapid plates, and that, in fact, the strength of the image was in exact proportion to the sensitiveness of the preparation.

We have already alluded to M. Gustav Le Bon's results with ordinary light. While M. Albert Nodon† exposed a plate behind several thicknesses of black paper for fifteen minutes, at a distance of ·4 metre, to an arc light of twenty ampères, and obtained no effect, the former experimenter, placing a negative on a plate, and over all a sheet of iron, and exposed to a lighted petroleum lamp for three hours, obtained a faint image, and a very decided and strong image when he enclosed the whole with a sheet of lead overlapping the iron at the edges. But others have failed, and M. G. H. Nievenglowski‡ repeated Le Bon's experiments in the dark without any source of light, yet obtained results similar to M. Le Bon's. In the current number of *La Nature*, giving details of the last sittings of the Academy, M. d'Arsonval confirms the latter *savant's* results, and exhibited superb results obtained by M. Henri Murat, of Havre, who, through a sheet of copper, obtained, by the light of an incandescent gas, a negative of the bony part of a skate, showing the fins, liver, and heart.

The most recent addition to the theoretical aspect of the discovery is that of MM. Gossart and Chevalier, who, to speak briefly, find that the Röntgen rays appear to extinguish heat effects. Thus, placing a Crookes' radiometer in their path, the experimenters found the vanes set in motion by external heat agency were stopped dead by the Röntgen rays. A field of force was created in the radiometer, and exercised its restrictive action upon the vanes for five minutes after the withdrawal of the Crookes' tube.

Mr. Watmough Webster has suggested to us a little while ago the possibility of increased photographic action being obtained by the sheets covered with fluorescent substances being placed in contact with the gelatino-bromide films, and thus reinforcing the action of the rays, and has further suggested that the Röntgen shadows be received on such a fluorescent surface, the visible image thus available to be photographed by an ordinary camera and lens.

Finally, we must advert to the latest development of the Röntgen radiation. We have referred to an obscure announcement, received with a certain amount of incredulity, that an Italian, Professor Salvioni, had invented an instrument, called an iristoscope, for seeing, instead of photographing, through opaque bodies. Working on the lines of Professor Salvioni's description, Messrs. Swinton & Stanton have devised an apparatus for the same purpose, and, writing to *Nature* last week,§ they give an account of their success. The Röntgen shadows are thrown on to a platino-cyanide of barium fluorescent screen, placed barium side inwards at the end of a blackened cardboard tube. Upon looking into the tube, objects were clearly seen, and beyond that, by a further adaptation of the method, they were easily able to ascertain which was the best part of the Crookes' tube from which to obtain the Röntgen rays.

The subject is now so wide that it is difficult to summarise its evolutions in a single article, but our readers may be sure that all important developments will be duly recorded in these pages.

‡ *Comptes Rendus*, p. 232. § P. 388.

The Picture Market.—We have occasionally referred to the extraordinarily high prices sometimes realised at auction sales for paintings by the old masters. As showing the fluctuations of the picture market we quote some of the best prices obtained by Messrs. Christie & Manson on Saturday last. *Meditation*, by Sir Joshua Reynolds, brought but 460 guineas, a Cuyp but 380 guineas, a Van de Velde 240 guineas, a Cosway 200 guineas, a Van Eyke 300 guineas, another Sir Joshua 220 guineas; *Cattle Reposing*, by Paul Potter, only fetched 110 guineas, a pair of paintings by Sir Thomas Laurence only brought 120 guineas, and another by the same artist but 105 guineas. *A Fête Champêtre*, by N. Jancret, which was exhibited in Manchester in 1857, however, was sold for 800 guineas. It is noteworthy also that a large proportion of the pictures in this sale were portraits; still, by such masters, much better prices would have been expected.

The Composition of Green Fog.—It is usually supposed that green or dichroic fog is confined to gelatine plates, and it is said to be the result of a combination between the gelatine, bromide of silver, and pyro, of the nature of a dye. But it is quite easy to obtain it in the most pronounced form upon collodion films under circumstances that entirely preclude the possibility of either gelatine or bromine forming part of its composition. It is usually also supposed to require the use of pyro and ammonia, though we have had it both with soda and with metol on gelatine films, and with metol on collodion. It is only with a very excessive dose of ammonia that we have succeeded in producing it upon collodion films in ordinary development, and under those circumstances it has appeared both with pyro and metol. But it is very easy to get it in the most intense form. We have even seen it in the following form. Let a collodion plate be fixed with hypo, and, after a fair amount of washing, immerse it for a short time in dilute solution of iodine. Then, in daylight, proceed to intensify with pyro and silver. The action will proceed quite normally for a time, the first departure from the proper course being the usual discolouration of the shadows. This goes from yellow to pink and ruby by transmitted light, and finally the green colouration by reflected light comes with an intensity that is seldom seen with gelatine. Here, although we have neither bromine nor gelatine present, we have pyro, organic matter, and the possibility of free halogen in the form of iodine, so that probably the original idea of its composition is not far wrong.

A Process Revealed in a Vision.—Many photographic processes, especially some of those which profess to solve the problem of photography in the colours of nature, may be described as visionary, but, so far as we can ascertain, only one person has ever declared that a process was revealed to him in a vision. An account of the episode will be found in the life of that erratic genius, William Blake, and, although the process in question is not a photographic one, it deals with a subject now nearly akin to photography, namely, the quick production of a printing block. It is not too much to say, perhaps, that in it we have the germ of the common zinco linework block. William Blake, even in his boyhood saw visions, and his persistence in his statement that he had seen angels on Peckham Rye greatly angered his good father. But the visitation to which we now more particularly refer occurred in his later life, soon after he had lost a younger brother to whom he was devotedly attached. He was at the time anxious to publish an illustrated book called the *Songs of Innocence*, but he was very poor and had no patron to befriend him. At this juncture the spirit of his dead brother appeared to him in a dream, and told him how the work could be done without the help of an engraver, and so impressed was he with the reality of his visitation that the next morning he spent his last half-crown on copper plates with which to commence the work. Text and illustrations were drawn on the copper in resinous ink, and the plate was afterwards etched in aqua fortis, leaving the lines of the design standing up in relief. This book is unique in the history of literature, and it is now very rare; it was issued in 1787.

A Suggested Use for the "New Photography."—Photography with the help of a Crookesian tube has evidently caught

on; at least, we are constrained to think so when we hear of its suggested use by Boards of Guardians at our workhouses. Let it at once be understood that they are not going to provide apparatus at the expense of the ratepayers for the amusement and instruction of the inmates—this may come later on—but at present they aspire to employ the rays for a different purpose altogether. It seems that the Local Government Board, seeking a new outlet for its energies, has discovered a flaw in our otherwise magnificent but costly system for the relief of the poor and idle. It has found that the tramps and vagrants who present themselves at the casual wards are not questioned by the authorities as to their religious belief. This shocking state of things could not, of course, be allowed to continue for one moment longer, and a circular was immediately issued to the Guardians with reference to the omission. The Guardians of one house of free entertainment have signified their heartfelt regret at the omission, but justify themselves on the ground that the refugees who come to them for succour are generally in such an advanced stage of intoxication that it would be difficult to get from them any concise statement as to their theological opinions. It is here that the "new photography" comes in, the suggestion being that the bump of veneration in these tramps should be examined *à la Röntgen*, so that its contents may be appraised. The notion is not so quixotic as it seems, for the rays so employed would meet with a great deal of brass—and this is one of the metals which is opaque to them. An interesting picture would therefore most surely result.

Tempting a Pharmaceutical Chemist.—At an inquest on a child, held at the East End of London one day last week, the mother said she went to a chemist and obtained a mixture for him, saying the baby had a cough. On this the Coroner is reported to have made the following extraordinary remarks:—"Do you know that is not lawful? A chemist is supposed to make up prescriptions you take to him, and not to prescribe; that is what a doctor gets his diploma for. Chemists are cheating the doctors when they prescribe, and they should not do it. You tempted the chemist to break the law." One might have surmised that, instead of the mother being reprimanded for tempting the chemist and druggist to break the law, the latter would have been censured, if not prosecuted, for breaking it. If the medical societies were to put their laws in force against phamaceutists as their Society persecutes photographic dealers and others, it would make a material effect on the returns of the majority of them, and probably many valuable lives would be saved annually.

A LITTLE while ago the Pharmaceutical Society recovered their penalty, of five pounds, from a well-known firm of oilmen for selling fly papers. The iniquitous administration of the Pharmacy Act was dwelt upon by the defendant's counsel, but the Judge, who evidently had little sympathy with the prosecution, said he did not make the law, he had only to administer it as he found it. Notice of appeal was reported to have been given. If oilmen, photographic dealers, drysalters, and others interested were to combine and agitate the matter, there is little doubt that the Pharmacy Act would quickly be modified, as well as the vexatious way it is administered by what is really a trade society and nothing else.

Are Orthochromatised Plates Myths?—This, in the year 1896, would appear to be an absurd question, were it not for the fact that it was stated at a recent meeting of the Croydon Camera Club, by Mr. White, that ordinary plates will, providing a full exposure be given, yield results in colour-rendering not inferior to those on orthochromatic ones. Naturally this statement was received *cum grano salis* by some workers, and was challenged by one gentleman. The challenge, however, the President of the Club writes, he would advise Mr. White to let severely alone. As a reason for this, he says he thinks it would be difficult to find an "independent and competent body" to decide the question, "for unfortunately, in the upper circles of photographic societies, there exists a most perverse objection to giving ear to the conclusions of practical workers."(?) He adds that "it has been one of the most notable curses of photographic advancement, that for years the road has been barricaded by the *débris* of laboratory twaddle, and the rubbish of text-books."

HOWEVER, the President of the Croydon Camera Club promises, in the event of Mr. White deciding not to meet this challenger, that he "will try and arrange for the publication, in one of the technical journals, of a paper, setting forth with more precision and fulness than is possible in a mere abstract, how Mr. White seeks to substantiate his case." We are sure there are a very large number of practical workers, with a decade or two's experience in the reproduction of paintings, both at home and abroad, who will look forward to the publication of this paper, and hope it will not be long delayed.

Vandalism at Hampstead Heath.—Hampstead Heath and its surroundings have always been a happy hunting ground for landscape painters, and many of their best works have been of that neighbourhood, notably some of those of Constable. Curiously enough, Hampstead Heath, and its beauties, seems to be but little known to London photographers. At one of the annual outdoor gatherings of the Photographic Club were several photographers, who had spent the greater part of their lives in the metropolis, who had never been to the Heath before; they seemed to have, as others have, associated the Heath only with "'Arry and 'Arriet" at "'Appy 'Ampstead" on bank holidays. Now the Heath is under the control of the London County Council, and its picturesqueness appears to be doomed. As most are aware, that body's idea of beauty is straight and smooth gravel walks, level greenswards, and neatly trimmed trees, and that idea is being carried out on Hampstead Heath, much to the disgust of artists and lovers of natural beauty generally.

A PETITION is to be presented against this vandalism. It is as follows:—"We, the undersigned artists and other admirers of the wild and picturesque beauty of Hampstead Heath, do most urgently petition the London County Council to put an *immediate and final stop* to some of the work now proceeding there, namely, the cutting and burning of the old gorse bushes, the filling of hollows in paths with sand taken from banks and knolls, the drying up of small ponds by throwing in ashes, mud," &c. Then follow the names of the petitioners, which include the President of the Royal Academy, the Vice-President of the Royal Water Colour Society, the President of the Royal Institute of Painters in Water Colours, some R.A.'s, literary men, civil engineers, &c. What effect, if any, this petition will have on the London County Council and its notion of the beautiful remains to be seen.

Reversed Negatives.—A week or two ago a correspondent made reference to the possible use of collodio-chloride emulsion for the reproduction of negatives by what is known as the nitric-acid process, in which, without fixing the plate, the image first formed is dissolved out by means of nitric acid, leaving the unreduced haloids to be darkened by alkaline pyro or other suitable development. Such, at least, is the mode of procedure when the image has been formed by development, the reduced silver being entirely soluble in nitric acid and other agents; but when it is formed by the continued action of light, or, as it is termed, by "printing out," its constitution is altogether different, and, although nitric acid has some action upon it, it entirely fails to remove it. It is not necessary here to discuss the much-vexed question as to the nature of the image under such circumstances, or whether the undissolved portion consists of subchloride of silver or what; the plain fact remains that it is practically insoluble, and thus collodio-chloride is altogether useless for the purpose of producing reversed negatives, at least when employed in the direct manner.

BUT we have seen very fair results obtained with a printing-out emulsion, though in a somewhat roundabout manner, and, though the process requires some care, it does not present any particularly serious difficulty. The printing is carried much further than would

be needful if an ordinary transparency from the negative were required. The plate is then washed, to free it from all soluble matter, and is then immersed for some time in a not too strong solution of iodide of potassium until the unreduced silver chloride is converted into silver iodide. It is next thoroughly washed and treated with a solution of bichromate of potash, to which a little hydrochloric acid has been added, by which means the image is bleached and converted into chloride of silver. We now have an image of silver chloride embedded in a layer of silver iodide, and, by taking advantage of the difference in solubility of the two haloids, the chloride can be removed without any great effect being produced on the iodide, which is then reduced in its turn to form a reversed image.

For the removal of the bleached image, a saturated solution of common salt, or a mixture of that with strong liquid ammonia—neither of which have much, if any, action on iodide of silver, though they freely dissolve the chloride—may be used. Very weak hypo or sulphite of soda will dissolve the chloride much more rapidly than the iodide, but such applications are difficult in use, owing to their solvent power on the iodide also and the consequent danger of unequal action; the first-named agents, though less energetic, are therefore preferable. The reversed image in iodide of silver requires for its reduction a very powerful alkaline developer, consisting of pyro and caustic potash, or it is possible, if the plate be soaked for some time in bichromate of potash or chromic acid, and thoroughly washed, it might be developed in the same manner as a wet plate by flowing it over with a solution of silver nitrate and, after a brief exposure to light, applying a solution of acid, pyro, or iron. The difficulties of the process are purely of a manipulative character.

DIGRESSIONS.

III.—Portraiture.

It was an Irish student, I think, who said there are three degrees of existence; you may live, or die, or vegetate. Portraiture has been vegetating for many years, and the time is coming when it will cease to occupy the neutral position, but must live or die. Monotony of splendid mediocrity can no further go. Everybody capable of rising has risen to a certain highly polished mechanical level; the residuum is left to make photograms. Take up any album of photographic portraits anywhere and, with few exceptions, it will be found full of precisely the same kind of work, it matters not from whose hand, or whose assistant's hand, or what part of the country. A glance backwards will show that we pass through waves of fashion in our art as in everything else. We are now in the show-case age of photographic portraiture and, let us hope, we are nearing the end of it—we have had it for ten or twelve years. Before that time, although not so good as has occasionally been shown to be possible, portraiture was sound and unaffected; now it is in the last degree puerile and trivial. It is "pretty." If there was a more contemptible word in the dictionary, I would use it.

There is this about this present series of papers above all others: it is a merit to digress, because the intention is to digress, and fulfilled intention is art. Therefore we will go back a few hundred years.

In painter's portraiture there have been many stages or periods in which the art appears to have been governed by fashion, yet the fashion has mostly been set by a master hand. The simplest student recognises the ages of Holbein and Vandyck, those of Lely and Kneller, helped, of course, by costume. These were followed by an era of minor but very prolific stars, some of them, indeed, were thought by their contemporaries to be the greatest geniuses of any age, but we of the present time have forgotten them. Poets of their own time perhaps exaggerated a little. One of them prophesies of a painter, now quite unknown,—

> "That future ages must confess they owe
> To Streater more than Michel Angelo."

(This following is an aside. What can painters expect when photographers are so easily forgotten? Only the other day a group of photographers in their best clothes, evidently attending some ceremony, was reproduced in a contemporary with a request by the editor for the identification of those represented, alive or dead. This is the only time I have been the object of a hue and cry, for I was one of them. Four of the other five figures are dead, but were, perhaps, the four best-known photographers of thirty years ago.)

Then came the splendid age of Reynolds and Gainsborough, and their famous contemporaries, which declined into the sweetness of Lawrence, who certainly succeeded in making ladies and gentlemen of his sitters, and the country was flooded by his imitators, who created the worst period of English portraiture, which lasted until photography taught painters what bad work they were doing, for which they have never been grateful.

A digression. I remember the bad time. In 1852 (that long time ago) I had my first picture in the Royal Academy Exhibition, and, of course, got the usual season ticket. I was so proud of having a picture in, that I visited the Gallery at every opportunity, and knew nearly every picture of that show by heart. And this is what I remember. Nearly every portrait had a cut orange and a silver inkstand, with a very large quill pen on the table, and a column and curtain background. Now, seeing that this background was authorised by every painter, is it wonderful that every photographer, in some cases against his own conviction, set up a column and curtain? The absurdity taught painters to think, and from that time, aided also by many other hints we have given them, portrait painting began to improve, and now some of our portrait painters give us work, perhaps with a little sameness of pose compared with the work of a good photographer, but equal to anything that has ever been done. It is now time we showed them how to carry the art a little further.

A personal digression. Many a doubting R.A. has consulted the old catalogue to see if it was true that a photographer could not only paint a picture, but get it into their show—a feat they found it difficult to believe. Rejlander also accomplished the same apparent impossibility.

We are now, I firmly believe, on the threshold of better things. The *Salon* is doing its work, and the public are at last becoming educated. Unfortunately, some of those connected with photography will have to suffer, but it will be only those who do indifferent work and cannot advance with the times. Photographers will have to be artists, not merely manufacturers or employers of labourers, and prices will correspond. There will still be room for poor work, but not for mediocrity. The cheap-and-nasty always flourishes. 'Arry and 'Arriet will still sit for their tintypes and "photograms" on the shore, but we shall return to pure photography, and the results, within the bounds of cultured civilisation, will be unboomed photography. In those days a photographer will be a photographer, and not a strange mixture of all sorts of trades and professions.

If portraiture is to recover its place as a profession, we must give up a good deal of the namby-pamby stuff of which every show-case is full. We shall have to give up retouching as it is now carried on. Ignorant "dotters" must not be allowed to spoil their eyes by sitting for hours smoothing, and taking the life out of, a single head, and must not suffer the simple revision of a negative to be turned into an exhibition of machinery in motion. It should be a Medo-Persic law that no man be permitted to give more time to a two-inch head than ten minutes, but then he must be a master of his art; so must he the photographer. Every extra minute spent on a head of this size does mischief. Of course there are exceptions to all rules, and an excessively freckled face may take longer.

Those of my readers who have any self-respect, have any desire for something pleasant to think of all their lives, and could manage it, of course saw the three exhibitions of the *Salon*, and, doubtless, remember the portraiture; and many, doubtless, also have tried to follow such excellent and apparently simple examples, and yet once more, doubtless, have been surprised to find how exceedingly difficult these apparently easy effects are to get. A casual visitor would have thought that in each case the sitter had just walked into the studio, that the exposure had been made, as you would let off a hand camera when you were flush of plates, any how, and there an end. This is the art that hides the art; you try that way yourself and fail. The

difference in the two cases was this. You allowed the sitter to be "so natural" all to himself while you were probably thinking of the number of seconds the particular quality of light would require; in the other case the sitter did as the artist wished unconsciously, looked as he mentally directed, smiled or frowned at his will, these emotions not being brought out at the word of command "your expression or your life," as sometimes happens, but *educed* with apparent carelessness, but really great pains and previous study. Just as the doctor when considering whether anything can save you looks pleasant, so does the photographer when he is bringing up his reserve powers. This is the photographer's substitute for what the painter calls treatment. The true artist takes the portrait long before he takes to the camera. The instrument is merely a detail. The sitter should be conquered long before it comes to that.

I wonder if America will think it a compliment if we go there for inspiration and perchance annex a hint. The novelty may have its pleasing aspect.

I always enjoy the *Photo Beacon*, although I do wish its title was not clipped. It is not a light beacon, as its name implies; its editor, I know, thinks it has more to do with photography than light-houses.

Looking through the number for last November, I came across a portrait that almost made me jump, it was so lifelike. It was not another portrait of that familiar young person, Aristo, or of the highly polished Ilo, it was a portrait of a man—the simplest thing possible. Full face, looking straight at you. Just the pose that it is the first rule of some portraitists to avoid. No attitudinising, no gush, no best clothes, no violent effect of light, not even out of focus; and, oh, rare quality! nothing about it of which an advertisement could be made (good work has beaten quack nomenclature). The sitter is not picturesque, but—*he is alive!* What is the secret of this effect?

This, and other pictures, are by Mr. W. M. Hollinger, of Dayton, Ohio, and we are told he exhibited, for the first time, at the last American Convention. The portrait in the *Photo Beacon* is accompanied by a few words, by Mr. H. F. Hoefle, with which we shall make free.

The colour values, the wonderful gradations, and, above all, the remarkable rendering of flesh, appeared to attract great interest to these pictures, and, what the ordinary portraitist will scarcely believe, the effect is produced almost entirely without retouching. Says Mr. Hoefle: "The flesh texture is easily got. Mr. Hollinger recognises that photography is emphatically the most perfect method of rendering texture of any kind the world has seen, and, believing this to be the case, has no hesitation in sending out much of his work absolutely free from the contamination of the retoucher's pencil, and where its use is absolutely necessary to remedy defects is as sparing with it as possible." He holds that every stroke of the pencil detracts so much from the quality of his work.

It may not be uninteresting to learn something of Mr. Hollinger's method.

"His studio side light is twelve feet by sixteen; the top light, which is at an angle of 30°, is twelve feet by fourteen. The glass is corrugated. Mr. Hollinger has entirely discarded the ordinary curtains, and depends for securing his effects upon a screen, which is placed between the sitter and the source of light. On this screen are a large number of little curtains, and, by drawing any one of them, he can let a flood of light in upon the sitter."

The screen described is a large frame of wood like a background frame, on which are arranged ten or a dozen curtains of a rather light, perhaps blue, material. This frame is placed near the sitter, and some of the curtains drawn, one at a time, until the effect of light and shade required appears. The high lights in this particular picture are strong, the flesh full of texture; there is not a bit of waxwork or ivory anywhere, the natural wrinkles are there without being aggressive, the light spots on the eyes are small and most effective, and, we are told, are the natural effect, and not due to the retoucher's pencil. Another delicacy is a rightly placed gradation in the backgronnd, which gives great relief to the head. Here we have a portrait that does not at first sight differ very much from the ordinary cabinet portrait, yet is so much above the usual production as to be distinctly individualistic, and almost to amount to a new style.

Here I see a rock ahead. I am not sure I am discreet in mentioning the screen of many curtains. Photographers are so easily led away by anything mechanical. When Adam Salomon sent some of his wonderful portraits to London (it is an old story), they were admired and studied with the greatest enthusiasm by many of our portraitists, who came from all parts of the country to see them. What was the result of all this enthusiasm and study? They all, with one accord, set to work to discover the secret of a kind of wax with which the famous photographer finished the surface of his prints. They found it. Astonishing to say, notwithstanding the great discovery, none of them got such good portraits as did Adam Salomon, but they got as good a polish!

Now, I don't want that screen of curtains to be mistaken for the secret of the almost boisterous life to be seen in this portrait. The real secret is clear. It is a perfect knowledge of what is best to be done and how to do it. How to do it is very easy; but it takes very earnest study to learn what is best to be done. Some of us don't know yet.

H. P. Robinson.

BY THE WAY.

It is scarcely possible to take up the pen to discourse on general photographic topics without making some reference to *the* subject of the hour—the "new photography," "shadowgraphy," "electrography," "sciography," or whatever it may please individual readers to call it; but, since I referred to the subject in my last notes, I have become so sick of it that I would fain have passed it over unnoticed on this occasion. I said last month that the impressions so produced are certainly not photographs, and I do not know which of the other terms enumerated above is the most detestable. Until it is decided under what head the mysterious X rays are to be classed, I would suggest that the pictures (?) produced by their means be called "Röntgeographs," as being at least as full of meaning, and at the same time doing honour to the discoverer.

It is never wise to prophesy unless you know, and in my last notes I referred to or hinted at the difficulties that lay in the way of experimentalists in this direction, and I imagined the new branch of research would remain in few hands; but, alas! for my judgment, in one short month every photographic society, from that of Little Peddlington downwards, to say nothing of other bodies "outside the pale," has had its demonstration, and, as a rule, the more remote the scientific centre, the more humble the demonstrator, the more wonderful the results obtained. As usual, it is in the "lay" press that we read of the most surprising variations from the original story; but I am not certain in my own mind whether to give credit to the inventive powers of the ordinary pressman or simply to "sheer cussedness" on the part of the great improver-of-other-people's-ideas for the statement that Edison is going to "Röntgeograph" his own or somebody else's brain. We are told on all sides that it is only the bony structure that is opaque to these "rays," while the softer and flabbier the tissue the more transparent it is; yet the "great improver," &c., is going to reverse matters and make the skull transparent and the brain opaque. An idea, however, strikes me. Professor Röntgen himself suggests that density more than anything else rules the transparency of any given substance to the X rays, and perhaps it will not be a very difficult matter, after all, to find a subject whose brain is actually denser than his skull.

But the height of bathos is reached when I find from an advertisement in the daily papers that the scientifically inclined can, for half-a-crown, witness the wonderful new process, or, for another five shillings, have a "Röntgeograph" of his head, or foot, or purse, or anything that is his! Surely there will be a rush for these productions.

Another of the "sensations" of the new year, to which I alluded in my last, seems to have fallen rather flatter than Professor Röntgen's discovery. I allude to that of the other Professor—Herkomer. It would be a pity, after all the talk about it, if the "new art" should prove a "fizzle," as seems likely, or be worked only by its inventor. I have not seen any of the accredited or avowed examples, unless, as is very possible, a portrait of "Dr. Jim" in, I think, the *Review of Reviews*, by Professor Herkomer,

was rendered "diffusible" by himself. If so, how are the mighty fallen if that is the correct "autographic touch" at the present day of the painter of *The Last Muster!* It is, I think, twenty years or so since I first stood almost in awe before that great picture, and more than admired the wonderful detail and singular naturalness of those portraits, for portraits they were; but I would not have believed it possible in so short a period for a hand to so completely lose its cunning. Stay, however; it may be the fault of the new process—art, I mean—which is perhaps, after all, not so free from the difficulties and uncertainties of "rocking" and "biting" as its inventor at one time believed. Perhaps the battery went out of order, perhaps the ink wasn't sticky enough, or the powder mixed in the proper proportions of coarse or fine, perhaps—ah, well!—perhaps a hundred things.

Speaking of Professor Herkomer's innovation leads me almost irresistibly to another new form of reproduction, of which at the present time Mr. Alfred Maskell is the champion. I allude to the system of carbon printing without transfer, whether by the Artigue, Demachy, or any other plan. There is, though, after all, nothing particularly new about it, since it was really the original method, and was only departed from when the transfer method or development from the back was found to give better results. As recently pointed out in these pages, such a process was commercially worked in America some ten years ago, but long before that. I think it was, the late Mr. Pouncy showed me some really very fair specimens of so-called "carbon" work executed without transfer, though I am ignorant of the details of the process, and long even before that I had read of the possibility of such results.

But Pouncy's process, as well as that described by Mr. W. H. Sherman, were intended for very different purposes from those to which Mr. Maskell and the more modern disciples of carbon printing without transfer apply it. These latter adapt the process to the ordinary every-day printing requirements, as I understand it, large or small, whereas Pouncy's and Sherman's processes were solely used for large work or enlargements. Now, any one at all acquainted with the latter class of work will readily understand how a method that may be thoroughly well suited to the purpose of supplying a groundwork upon which a finished picture in black-and-white or in colours can be built up by an artist may be just as hopelessly unadapted to the production of a finished result without such extraneous aid, just as the method and style of the scene painter would be useless in the hands of Miss La Creevy and her class. It is quite true too that the effects sought after by the new school of "pinholists" and "fuzzytypers" may be arrived at by means that would scarcely satisfy the cravings of the majority of photographers, and which would scarcely be expected to do justice to the capabilities of our modern lenses.

The process is only a means to an end, and each individual is free to select and use that which best meets his requirements, for which reason I am not in any way finding fault with the methods championed by Mr. Maskell. Where I join issue with him is in bringing a "charge of false teaching and want of knowledge of this subject against our scientific makers of text-books." That the text-books are strictly correct in teaching that a *perfect* carbon image can only be produced, so far as is present known, by development from the back, needs very little argument, and I scarcely think that any impartial critic, blest with a "judicial mind," would, on comparing the results of the two methods, hold that the Artigue process was the more perfect. That a certain sort of result is thus obtainable, suited to certain purposes, is beyond doubt, but it would be as reasonable to call it the perfect method as to hold that the best way of compounding a gelatine emulsion is to stir precipitated silver bromide into a pot of melted glue! Perhaps a pinhole negative is not improved by printing it on to surfaced paper, with the highest "bonbon-box" finish, and, *per contra*, I really don't think the definition of a modern Zeiss lens would be augmented by having recourse to the modern revival of the earliest of all carbon-printing methods.

Talking of text-books suggests a reference to a letter from Mr. Hector Maclean, at page 126, in which I find the following extraordinary piece of argument (!): "It has been one of the most notable curses of photographic advancement that of years the road had been barricaded by the *débris* of laboratory twaddle and the rubbish of text-books." It is for this, then, that Vogel, Waterhouse, Eder, Schumann, Bothamley, Abney, Ives, Tailfer, and a host of other workers in the same direction who have hitherto been supposed to be capable men and to know something of what they have written about, have spent years of wasted time—to write "twaddle," and fill the text-books with "rubbish." It is due entirely to their misguided efforts that hundreds of photographers, the world over, have for years been content to pay enhanced prices for so-called orthochromatic plates, upon the perfection or supposed perfection of which thousands of pounds, dollars, and francs, have been spent in this country, in America, and on the Continent; but, to the credit of old England, and of Croydon in particular, it is in our native land that the error has been exposed! All the same, Mr. Maclean, yours is scarcely "argument," as we understand it in this country, though it might do for the editor of the Texan or Californian *Pocket Handkerchief.*

So far as the question in dispute is concerned, there is much to be said on both sides—that is, at least, so far as the use of ordinary plates with the coloured screen is concerned; but to assert, as I take it Mr. Maclean does, that better results in colour-rendering can be obtained with ordinary than with properly colour-sensitised films is simply absurd, and is more, I fancy, than the author of the paper he attempts to defend ever dreamt of claiming. In the early days of orthochromatics I was strongly of opinion, from theoretical considerations, that *as good* results, under certain conditions, could be got with a screen on ordinary plates as upon orthochromatic—not better, be it understood, nor even as easily; but, upon putting the matter to the test of practice, I was compelled to acknowledge myself beaten. The more recent investigations of Mr. Ives and others prove that I was not altogether wrong, and, no doubt, the cause of my failure lay in the want of a suitable screen: but, even granting the possibility of arriving at colour-correct results with ordinary plates, it will stand to reason that they must be inferior—in convenience, at any rate—to films specially prepared for the purpose.

It is, perhaps, not beyond the memory of many of your present readers that, so far back as 1880 or thereabouts—in the early days of gelatine plates, at any rate—the late Mr. J. R. Sawyer read a very interesting paper before the Photographic Society, in which he showed, if I remember rightly, that the most correct rendering of the majority of colours was obtained with ordinary bromo-iodised collodion, its competitors being other kinds of collodion, as well as gelatine with and without dyes. The chart illustrating his paper was published in the Society's journal, and forms a very interesting reference at the present day.

DOGBERRY.

FOREIGN NEWS AND NOTES.

Images Due to the Oxidation of the Developer.—In the *Photographische Correspondenz*, Liesegang, continuing his researches relative to images due to the oxidation of the developer, remarks that amidol, under certain conditions, will yield such results. A negative developed with pyro and ammonia still retains a printable image after the silver has been removed with bromide of copper and hypo. If amidol be mixed with an alkali, exposure to the atmosphere or to the air contained in water will yield an intense blue product due to oxidation. Make a developer with amidol and bicarbonate of soda. In use it will take on an increasing violet colour. The negative is stained, but after fixation the deep shadows are clear, and the stain is in proportion to the deposit of silver. Treatment with bromide of copper and hypo discloses the fact of a red to red-brown image, without much reduction by removal of the silver. It would therefore seem that under such conditions the negative owes its intensity principally to stain. The wet negative shows little relief, consequently the stain does not possess much tanning property. Pyro-ammonia and alkaline amidol developers are therefore to be recommended for plucky negatives, full of detail, and for positives of warm tone.

Adolph Menzel.—On December 8 the great German painter, Adolf Menzel, completed his eightieth year, and was the recipient of

high honours. Deputations congratulated the veteran, and by imperial favour he was created Privy Councellor with title of Excellency. The Berlin Photographic Society also offered him honourary membership, which he accepted. Unlike most painters, Menzel has been a staunch friend of photography, and has known how to appreciate its value. According to the *Photographische Mittheilungen* he may claim to be the first retoucher of negatives of oil paintings. Before the advent of orthochromatic photography he corrected the tones in negatives of his pictures with his own hand, and such a master was he of negative work, that he once painted a negative picture in carmine upon a glass plate. Menzel related an incident in connexion with his picture of the coronation. This work was four years in hand. Some personages had died, and others could not come to Berlin. Count Dohna was of the latter, and Menzel made use of a photograph. But subsequent circumstances brought the Count to Berlin, and Menzel immediately saw that the photograph did not represent the man. Ten minutes sufficed for a sketch, the portrait was repainted, and after a lapse of many years Menzel had the satisfaction of being congratulated by Count Dohna's son upon the excellence of the portrait. Menzel prefers photography to engraving for the reproduction of his work, but he warns the painter to use it as little as possible in painting.

An Example to be Followed.—The Technical Institute at Vienna, with characteristic enterprise, is arranging a section for the letterpress and illustration industries. The City of Vienna provides the site, the Government the funds, and the Printers' and Type-founders' Association a portion of the presses, &c. A large collection of pictures, illustrative of the graphic arts, has already been made, and next September, it is expected, the school will be opened. Practical and theoretical instruction will be given in all branches. Where are we to look for such work in this country?

Prizes Offered.—Messrs. Voigtländer & Son of Brunswick, recently offered three lenses of the value of 20*l.*, 15*l.*, and 10*l.*, for the three best pictures taken with lenses of their make. The right to reproduce the successful pictures shall vest in the firm. They also stipulated for the right to reproduce any of the pictures sent in, upon terms to be arranged, and any photographs they may decide to keep they will pay for at stipulated prices. The Judges were one member of the firm and a well-known portrait photographer.

Payment for Sittings.—The *Deutsche Photographen Zeitung*, in reply to a correspondent, publishes an article on the question of general notices to the public concerning payment for sittings, retention of negatives, &c. It appears that the Berlin Photographic Association has printed such notices for its members, and they carry the authority of the Association's name. The *Deutsche Photographen Zeitung* points out that, much as the best houses might wish to help other members of the profession, such questions cannot be dealt with by hard-and-fast rules. The conditions of each business must be studied. At some establishments such notices would offend, and the effect might be a universally equal, but lower, status.

Spotting Gelatine Prints.—For spotting highly glazed gelatine prints A. Helheim recommends the use of aniline colours dissolved in alcohol, one part of rose aniline with two to three of ethyl green. The addition of a little blue may at times be necessary. The colour dries almost immediately. It is preferable to use little colour, and by repeated strokes with the brush attain the desired tint. The colour may be removed with a clean brush moistened with alcohol, and the surface does not suffer.

Process Plates in 1884.—Liesegang remarks that his friend A. Davanne recollects process plates being produced by Manzi, in 1884, at Goupil's, of Paris. Liesegang confirms this, an etched copper plate having then been placed at his service by the firm. The sample prints sent with it were good. But it appears that the network was so fine and close, that, owing to the backward state of the art of printing at that time in Leipsic and Berlin, any thing approaching the proofs from Paris could not be produced. He was therefore compelled to return the plate unused. Even at the present time Manzi's plates require great care in printing, good ink, and good presses. For these reasons the prints cannot be produced cheaply.

COLOUR SCREENS IN PRACTICAL PHOTOGRAPHY.

As the use of orthochromatic plates is becoming more and more general for the best class of work, it may be well to consider what is the most efficient form of screen for use in connexion therewith.

At the outset it will probably be readily conceded that, while the manufacture of orthochromatic plates has been brought to a high state of perfection and efficiency, the necessary screen for obtaining the full value of the plate lags behind in the background, and is enshrouded in as much mystery as a Salon masterpiece. What proportion of the workers of to-day are able, with any confidence, to select a screen from a dealer's stock that is really suitable for their requirements? Certainly the variety is not likely to be large enough to cause the confusion and hesitation one sometimes notices. No; the truth is, few workers know what a screen ought to be, or what they want it to accomplish. It would probably be amusing, if not instructive, if a collection of screens of all the colours of the spectrum could be placed before some otherwise capable workers for selection without any advice from the dealer; it might resolve itself into a matter of political bias. There are screens of optically worked glass of various colours and shades, single and compound; others of dyed films of both collodion and gelatine; and, again, a small glass trough holding a coloured liquid, which is known as a cell. Coloured glass plates are largely used, but the difficulty at present of getting coloured glass with any degree of regularity, having the necessary properties, is so great, that I need not further allude to it here. A combination of such glasses is the subject of a patent. Coloured films of gelatine or collodion are used by some workers with excellent results, but they are necessarily fragile and require much care to make. The cell has perhaps more advantages and fewer defects than any other form of screen.

Mr. Ives has shown us that it is not so much a matter of any particular shade of colour as the selection of a suitable colouring matter. Some colouring matters have the power of cutting off certain rays of the spectrum which it is desired to reduce, or wholly eliminate, as the case may be, in a much greater degree than others, although apparently giving a similar shade of colour; but, whatever colouring matter is used, depth of colour means increase of exposure, and it is quite possible to have a screen which, while requiring long exposures, is less efficient than one of a lighter shade, requiring much shorter exposures but composed of a suitable colouring matter.

As these remarks apply solely to the use of orthochromatic plates, which, as every one knows, are specially rendered more sensitive to the less actinic rays, and less so to the more actinic, we do not need a screen of such great power in cutting off the violet and ultra-violet rays as when experimenting with ordinary plates; but, even with orthochromatic plates, perhaps the simple aqueous solution of chromate of potash, so far as our present knowledge goes, is the most reliable of all; it is cheap, no skill is required in its preparation, and the tint can be varied to suit every class of plate and subject.

Plain glass cells can be obtained ready-made, but they are rather costly, and can be made at home with little trouble for a few pence. Of course, theoretically, the glass sides ought to be optically worked, but the results of many experiments made to determine this point have satisfied the writer that no one need hesitate to use a good quality of fine plate glass. Certainly the tests were made with the anastigmats of Zeiss and Goerz, but the reader may take it as a fact that optically worked glass is not absolutely necessary for pictorial work. For those who wish to make their own cells the following simple instructions will suffice:—Procure two plates of fine plate-glass, about the one thirty-second part of an inch thick, of suitable size to cover well the lenses with which it is to be used. Three inches square is a good size. Place between these two plates another piece of plate glass, the thickness you desire to make the cell, say, one-eighth of an inch, taking care the central plate is rather smaller than the two outer plates, say, two and a half inches square. Now place the three plates in a vice, such as is used for binding lantern slides, carefully noting the contact is firm, so that the sides of the cell are perfectly parallel. Then cut four strips of sheet celluloid, of such width as

the outer glasses, which can be cemented on them with celluloid varnish, laying the varnish carefully on the edges of the outer glasses with a small brush, then neatly laying on the strips of celluloid, which should just fit the sides. Make up three sides of the cell in this way, and leave in the vice until quite dry and firm, then take it out, and remove the central piece of plate glass by shaking it out of the open side. You now have a simple cell, which can be filled with any coloured solution required, and used in the studio for experimenting with the top open; but it is better to make it tight by cementing on the fourth strip of celluloid after first drilling a small hole in the centre, of sufficient size to admit the tube of a pipette, which is a handy instrument for filling, emptying, and changing the coloured solutions to be used. When the cell is charged, a small plug of indiarubber can be inserted in the hole, and it is then ready for field work of any kind.

The celluloid varnish is merely a jelly made by dissolving a bit of clean celluloid film in a small quantity of amyl-acetate. Being impervious to water, it answers the purpose admirably.

The particular colouring matter to be used for filling the cell must be decided upon by the worker; but, for those who have little knowledge of the subject, I advise a solution made up of one part pure chromate of potash to three hundred parts of distilled water as a commencement. The strength can be afterwards increased as the knowledge of the worker extends, and he can also experiment readily with other colouring matters, recording results for the benefit of his fellow-workers. F. H. Burton.

ON THE SOLUBILITY OF SILVER IN HYPOSULPHITE OF SODA.

I have from time to time read with much interest the remarks on the above subject in this Journal, and for a long time hesitated between two opinions, as an experiment at one time would flatly contradict an experiment at another. Even now I have never made any systematic attempt to solve the problem, but found my opinion on the effects I have noticed from time to time resulting from almost identical manipulations under different conditions. The conclusions I have drawn are, that the varied results are owing to two causes: difference of temperature and fineness of the divided metal. For example, a negative on a gelatino-bromide plate, developed with pyro-soda and much too dense, left all night in the fixing bath, was almost entirely dissolved by morning. It was hot summer weather, and the dark room was almost unbearable with heat, owing to a large gas burner in the lantern which was going all day, and the ventilation of the room being very faulty. The consequence was that the hyposulphite bath was very much hotter than usual, although the strength of it was doubtful, having fresh crystals added to it from time to time, when the fixing seemed rather too slow.

Under similar circumstances, but with a lower temperature and pyro-ammonia development, an all-night soaking seemed to make no difference. The negative was too dense when it was put in, and too dense when it was taken out. At other times I have found too dense negatives considerably reduced by leaving them in the hyposulphite for an hour or so, and sometimes it made little or no difference. I am uncertain as to the kind of development used, but it would have been either soda or ammonia and pyro; but, in all cases of reduction, it was during hot weather, and using gelatine plates. I have no recollection of *ever* finding a *wet-collodion* negative altered in density in the least by prolonged immersion in the fixing bath of hyposulphite of soda; the *colour* of the image was considered rather improved if hyposulphite of soda was used instead of cyanide of potassium, and on that account alone it was preferred for some kinds of work that did not require after-intensification. Is it that the silver is in a much finer state of division in the gelatine plate than in the collodion one, and is there any difference in silver reduced from iodide and bromide salts that would account for it dissolving from a gelatine plate and not from a collodion one? An albumen print *well toned with gold* can easily be reduced by leaving it in the fixing bath longer than necessary to properly fix it: also a too strong solution of hyposulphite will, in the usual time allowed for fixation, reduce the prints considerably; but I have not seen the image *entirely* obliterated, toned or untoned; but a gelatino-chloride print untoned will be entirely dissolved or obliterated in a comparatively short time in a moderately strong solution of hyposulphite, especially if set in the light. The images, both on negatives and paper prints, are supposed to consist in the main of reduced silver, so there should be some analogy between them so far as the solubility of the silver goes.

Another question arises: Is the *apparent* loss of density, when it does take place, owing to the actual solution of the silver, and its removal from the film, or is it merely altered in character, so that it admits of the more free passage of the light? If a negative on a gelatine film, after being dried, is sprinkled with water, and the drops allowed to dry on the surface, their position will be readily seen by spots of less density, which, however, will barely show in the print; but, if the plate is again soaked in water and dried, these spots entirely disappear; but, if drops of moisture are allowed to remain on the surface when the plate is dried for the *first* time, no amount of soaking afterwards will get rid of them. In either case nothing can have been removed from the plates, although the density is considerably altered. For my own part, I am at a loss to satisfactorily account for the effect; perhaps some other of your readers can explain it. E. Dunmore.

ON MAKING NEGATIVE REVERSALS WITH CERTAINTY.

[Lewisham Camera Club.]

In nearly all the mechanical processes of photography, and in the carbon process, it is either necessary or desirable to have a negative in which the sides of the picture are reversed.

Many methods have been devised for accomplishing this object, but most of them are so uncertain, that they cannot be adopted in practical work.

The one most generally adopted by the trade is by stripping off the film of the negative, and turning it so that the left side becomes the right, and *vice versâ*. In the hands of experienced operators this plan is fairly successful, but it occasionally fails, and then, as usual, with the most valuable negatives.

One firm, to my knowledge, in this way spoiled some most valuable and unreplaceable negatives, which led to legal proceedings and their financial ruin.

To obviate such a catastrophe, some take the precaution of taking a print from every negative before stripping, so that a copy may be made in case of disaster. Another method frequently used is to take a transparency in the camera with the film of the negative outwards, and from this making another negative, which will be reversed in the course of reproduction.

The method of using a reflector or prism is seldom adopted, as it necessitates its use at the time of taking the original negative, which is seldom practicable, and would not be available for the vast number of negatives now in existence. Several other methods have been suggested which depend upon the use of some chemical added to the developer, but are regarded as curiosities of development more than anything else.

Recently attention has been called by one and another to the well-known fact, that prolonged exposure to light in the camera or otherwise produces reversal.

Over-exposure producing thinness and flatness of the image is the first stage of reversal. This knowledge does not appear to have been utilised, nor has any systematic method of working been given which would result in satisfactory reversals.

For some time I have been interested in the study of this phenomenon, and about a year ago, in turning over an earlier photographic publication, I came across an article on this subject by Mr. Bishop, which I had previously seen, and passed over as only another whim and fad on this question. This time, on reading it more carefully, I thought there was something in it worthy of trial, especially in that it pointed out the necessity of long exposure to obtain a good result, and that poor, thin, foggy reproductions were the result of under-exposure, &c. I set to work to ascertain the critical point of exposure required with an ordinary negative of fairly quick-printing quality. I began by giving a series of exposures varying from a fraction of a second up to 120 seconds and over.

I gave two exposures on the same plate, one being double that of the other, and it was interesting and instructive to watch the changes occurring from a positive image to a perfect reversed negative, and then by degrees a period was reached when no developable effect was made on the plate, and which, when fixed, was clear of any deposit of reduced silver. This last result was obtained by burning three feet of magnesium ribbon about three inches from the printing frame, and the plate was in the developer half an hour.

I had many failures before being able to satisfy myself when the exact point of exposure necessary had arrived, for, unlike the appearances of a plate exposed and developed under ordinary circumstances, flatness and lack of density may arise from under-exposure, whilst hardness and want of detail may be the result of over-exposure. But, again, great over-exposure will reduce both detail and density, which is a second stage of re-reversal, and it takes some little experience to be able to judge correctly.

The result of many experiments proved that, with an average quick-printing negative, an exposure in a printing frame to daylight sufficient to tint a piece of the paper in Watkins's actinometer to his standard, would produce on development a nice clear negative; but, of course, this depends entirely upon the density and colour of the original, and the same judgment is required as in making a bromide print. The method I have adopted of regulating the exposure by this standard is a basis of certainty never hitherto proposed or attained, and is independent of the varying actinic properties of daylight.

Once the negative is classified according to its density and printing qualities, the making of reversed negatives becomes a positive and certain operation. It has been my endeavour to select some other standard of exposure for those who either have no actinometer or available daylight at their disposal, and I find that one foot of magnesium, once burnt about three inches in front of the printing frame, is equal to Watkins's standard tint, and the experiments I make to-night will be with this mode of illumination. There are cases where negatives, either through faults in development or intensification, are so dense that no light can penetrate the high lights in any reasonable time, and, as a reversal requires that sufficient light shall have acted upon the densest portions in order that it may be developed to sufficient opacity, it is necessary that a preliminary exposure shall be made to equal in its totality that received under ordinary circumstances in the camera, so that the desired result may be obtained.

All negatives with great contrasts should have this preliminary exposure, or the reversed negative will be harder than the original. The development may be by any of the usual formulæ, but more strongly restrained, and the colour and character of the reversed negative will be affected by the developer used. In many cases the new negative will be better than the old one; a hard one may be made softer, and one with great detail but flat, can be made to have greater contrast, but where there is no detail, it cannot, of course, be produced in the new one.

It is not my intention to deal with the chemical questions involved in the phenomena under consideration. They have not been resolved by any theory yet proposed; but, there is, doubtless, an oxidation of the silver haloid which is rendered to some extent undevelopable.

In the practical demonstration I give you I hope to convince you of the ease and certainty with which these phenomena can be produced, and to show you how the knowledge may be utilised in the duplication of negatives for any and every process, and where reversal does not destroy picturesque effect.

[Mr. Eastwood, at the conclusion of his paper, exposed several plates behind negatives, the majority of which he had not previously seen, and was very successful in producing splendid results from all. He also showed a very large number of negatives, and the reversals from them, those that were originally too hard being in the reversal nice and soft, and the flat ones the reverse; but the result that attracted most attention was the one previously mentioned that had received an exposure to three feet of magnesium ribbon, the result was a plate so clean that it hardly seemed possible that it had ever been exposed at all.] E. Eastwood.

NOTES FROM THE WEST OF SCOTLAND.

No doubt very many photographers will remember with pleasure Glasgow's first International Photographic Exhibition which was held in the autumn of 1891, and which attracted such large crowds of visitors from all parts of the United Kingdom.

For some time past there has been a strong desire on the part of a large number of prominent amateur and professional workers that another Exhibition should be inaugurated at no distant date, and we are glad to be able to announce that with Mr. George Chalmer's installation, as President of the Glasgow and West of Scotland Amateur Association, something like definite steps have been taken towards furnishing the scheme, the Council of the Association having passed a motion to arrange for the necessary preliminaries towards holding the Exhibition in Glasgow during the autumn of 1897.

There was a strong probability, at one time, that the autumn of this year would have been chosen as the time for holding the Exhibition, but one or two insuperable difficulties cropped up that necessitated the date being placed into next year. Much satisfaction is felt locally that this scheme has now assumed something like a definite shape.

At the opening of the Paisley Photographic Societies Exhibition a very large gathering attended, and one or two new features in connexion with photography were inaugurated. Perhaps there is no society in the kingdom, that can boast of such excellent rooms for holding an Exhibition as those placed at the disposal of the Paisley Society in the Museum Buildings, and it would appear that photography has taken a firm hold of the citizens of this most important business centre. One of the features of the opening night was the production by Mr. Stewart Clark, who kindly presided on the absence of Sir William Dunn, of a most interesting collection of calotype negatives taken by his father upwards of fifty years ago, when Mr. Clark was a mere boy, and who roamed about, attending on his father, when these paper negatives were produced. Mr. Clark made a most interesting address in which he described and contrasted something of the old style of working when he was a boy, as against what he now sees practised by his boy, who, it may be stated is also a most enthusiastic worker.

Lantern nights, at least so far as the west of Scotland is concerned, appear to be losing somewhat of their attractions for the photographic public; for several years, no doubt, there has been too many of such held, until they have become quite stale, as the saying goes.

So we are to have social nights, in which ladies can take a prominent part. These will comprise music and several other interesting items on the programme. The first of these meetings will be held in the Christian Institute on March 6, tickets for which are all taken up already.

WEST LONDON PHOTOGRAPHIC SOCIETY'S EXHIBITION.

The Seventh Annual Exhibition of the West London Photographic Society was held on Friday and Saturday last, February 28 and 29th, at the Broadway Lecture Hall, Hammersmith, which, up till two years ago, was the venue selected for the exhibition, the Society in the interim having occupied a hall at the School of Arts, Bedford Park.

The Exhibition, which was confined to members, comprised nearly two hundred photographs, and was in every respect an excellent one, the evenness of quality displayed being very noticeable. Prominent among the exhibitors were Messrs. Harry Selby, Leslie Selby (President), J. J. Adam, J. Stein, G. Lamley, M. W. Cockerell, and G. F. Blackmore. The first-named contributed what was undoubtedly the gem of the collection, a wet-harvest scene, the effects of steamy atmosphere and bright foreground reflections aiding materially towards securing a most realistic and artistic effect out of very simple materials. He also secured the medal for the best lantern slide.

The Society has vastly improved on last year's Exhibition.

SOUTH LONDON PHOTOGRAPHIC SOCIETY'S EXHIBITION.

The South London Photographic Society is now holding its Seventh Annual Exhibition at the Camberwell Public Baths. The proceedings were opened on Monday evening by the Marquess of Londonderry, K.G., who, in declaring the Exhibition open, in a few well-chosen words, referred to the progress photography has made in recent years in its application to pictorial expression, and also to its latest scientific developments. He also briefly recounted the progress of the Society as shown by the entries for its Exhibitions, the first attracting no more than ten exhibitors, and the present one just one hundred.

The Judges originally announced were Captain Abney and Messrs. E. J. Wall and L. Warnerke; but, Captain Abney and Mr. Warnerke being unfortunately prevented from acting by illness, Messrs. W. E. Debenham and John Hodges were invited to fill their places. The exhibits are over 400 in number, and are divided into fourteen classes, of which eight, A to H, were reserved for members. Silver and bronze medals were awarded at the discretion of the Judges.

In Class A (Portraiture and Figure Study, including Animals), a silver medal was awarded to J. T. French for a cottage interior, with figures, which, although not quite real-looking is sufficiently so to bear all but a most critical examination, and considerable ingenuity has been displayed in the construction of the picture. Class B (Architecture) is certainly the best class in the Exhibition, and consists of a collection of architectural studies that does credit even to a Society famed for the excellence of the work of this kind performed by its members as is the South London. Silver and bronze medals were awarded to Messrs. E. R. Bull and C. F. Dickinson respectively, but the Judges must have had some difficulty in making these decisions, at least half a dozen other exhibits being nearly equal to the selected ones. In Class C (Landscape and Seascape above half-plate), the Judges awarded a bronze medal to Howard Esler for a study of bare branches entitled *A Winter Noon*, and a second bronze medal to J. Millis for *A Monarch of the Forest*, a picture remarkable, in these days of gloom and murkiness, for its bright effect of sunshine. Class D (Landscape and Seascape, half-plate and under), Mr. A. E. Allen was fortunate in securing a bronze medal for *Swanbourne Lake*, a bright little picture so sharp in its definition that it might serve as an advertisement for a lens-maker. Class E (Enlargements) is not a brilliant class. The bronze medal was given to C. F. Dickinson for a figure subject of little merit; as a piece of technical work, however, the enlargement is a good example. C. F. Dickinson is also awarded a silver medal in Class F, for a set of six views of Salisbury Cathedral admirable for their artistic as well as their technical excellence. In Class G (Pictures taken at a Society's Excursion), Mr. Dickinson is again successful, a silver medal being awarded him for another view in Salisbury Cathedral, while a view of the west front of the same cathedral brings Mr. French another medal, bronze this time. In the Hand Camera Class a pretty little picture, by W. D. Welford, obtains a bronze medal. The class is by no means a strong one, and most of the pictures might have been the results of time exposures.

In the open classes, the Champion Class, as is so often the case, is extremely weak. A silver medal is, however, awarded to *A Study*, by Mr. G. Lafayette. The general open class also is not a very strong one as regards quality. A zoological study, by Mr. H. Sandland, is awarded a silver medal, the subject being *Polar Bears*. A pretty little picture, which well carries out its title, *Lingering Mists*, receives a bronze medal, and another bronze medal is awarded to Mr. C. E. Fairwise, of Washington, U.S.A., for *A Chase for the Butterfly*. In the class for lantern slides that have been previously medalled, Mr. George Hankins adds another silver medal to his now numerous collection for six slides of various subjects, and in the general open lantern-slide class the South London Society gains a distinct triumph, both the silver and bronze medals being awarded to members in competition with all comers. Mr. C. F. Dickinson gains a third silver medal for a set of architectural slides, and Mr. Howard Esler a bronze medal for a set comprising various subjects.

In a class for process work Howard Esler has the field to himself, there being no other competitor. His work deserves mention for its

excellence. Silver and bronze medals are awarded to Mr. A. Seaman, of Chesterfield, and Mr. A. W. Westropp, for stereoscopic slides.

The Apparatus Section makes a brave show. Among the exhibitors are Messrs. Bender & Co., Howell & Co., W. F. Slater, F. S. Thorn, H. F. Viner, E. H. Wilcox & Co., Parkes' Drug Stores, Limited, and The Prosser-Roberts Company. The last-named firm receive a medal for a hypo-solution bottle, graduated so as to avoid the necessity of weighing the salt, and Parkes' Drug Stores also receive a medal for the most effective stall.

WOOLWICH PHOTOGRAPHIC SOCIETY'S EXHIBITION.

The Woolwich Photographic Society held its Second Annual Exhibition of Photographs and Apparatus on Thursday, Friday, and Saturday, the 27th, 28th, and 29th ult., at St. John's Schoolroom.

In the Members' Class the number of exhibits—174, the work of twenty-eight members—is a testimony to the activity of the Society. Among the pictures there was a considerable number which did credit to their Exhibition and to the society; but we cannot avoid the impression that the Exhibition, as a whole, would have gained had a wise discretion been exercised in the work of selection. There were some photographs on the walls which, we think, were amongst the worst we have ever seen publicly exhibited. The loan collection included works by such well-known names as F. W. Edwards, C. H. Oakden, H. Esler, A. Pringle, J. C. S. Mummery, most of the pictures being old-fashioned friends; and enlargements, photogravures, &c., by Messrs. Morgan & Kidd, and the Autotype Company, also assisted to decorate the walls.

The trade section made a goodly show, the stalls being occupied by Messrs. R. & J. Beck, W. Butcher & Son, B. J. Edwards & Co., Marion & Co., D. Noakes & Son, Walter Tyler, Thompson & Son (Manchester), The Filmax Co., The Thornton-Pickard Co., and T. H. Powell, the local dealers, Messrs. E. C. Carter & A. J. Wing, also being represented.

In addition to that afforded by the exhibition of pictures, plenty of amusement was provided for visitors, there being an admirable musical programme for each evening, and a lantern entertainment, while a new and popular feature was introduced in a demonstration of the method of obtaining shadowgraphs, by means of Röntgen's X rays.

NEWTON'S NEW HIGH VACUUM "FOCUS" TUBE FOR ELECTROGRAPHY.

Messrs. Newton & Co., of 3, Fleet-street, E.C., have introduced certain modifications into the Crookes' vacuum tube used for "photographing" by the Röntgen rays, which have the dual advantage of shortening the exposure, and, so to say, focussing the impression. Hence the term "focus" as applied to these tubes, of which Mr. Alan Swinton writes to Messrs. Newton as follows:—

"I have exposed several plates to the new 'focus' tube that you kindly sent me this morning. The results are exceedingly good, and surpass in sharpness any that I have so far obtained.

"The necessary exposure seems also to be remarkably short. In particular I have taken a most successful elbow joint with two minutes' exposures. A hand which shows in a surprising manner the texture of the bones with one and a half minute's exposure and a mouse with one minute's exposure.

"All leave little to be desired except that the mouse would have been better with a shorter exposure.

"It is my opinion that the designer of this new tube has made the greatest advance so far known as regards the practical application of Röntgen's photography."

In order to give us an opportunity of judging of the improvement in the results obtainable with the focus tube, Messrs. Newton kindly took an electrograph of the very hand that is writing these sentences, giving an exposure of two minutes and producing an excellent result which allowed us to contemplate the structure of our finger bones. The detail and sharpness of this negative and one of a pair of eyeglasses electrographed through a leather case were so remarkable that we have no hesitation in endorsing the praise Mr. Swinton has passed on the Newton Focus Vacuum tube.

The Inquirer.

*** In this column we shall, from time to time, print questions that may be addressed to individual contributors to our pages, or such as are sent to us with the view of eliciting information from a variety of sources. We invite the co-operation of our readers in rendering this feature of the* JOURNAL *useful and instructive.*

Collodio-Chlordie Paper.—"Wet Plate" says: "I want to prepare a collodio-chloride paper with the following qualities: very thin film, for partly printing, and then developing to right depth, and toning to ordinary print out colours, and also for transferring whilst still wet, if possible. Can any one assist me?"

The Nature of the Collodio-chloride Image.—"W. B. B." writes: "Referring to your remarks in last issue (p. 144) on the non-action of nitric acid on the printed-out image of collodio-chloride, have you or any of your readers noticed the following peculiar circumstance: I tried the effect of nitric, hydrochloric, and nitro-hydrochloric acids on the reduced silver deposit, the emulsion being poured, for the purpose, upon white card upon which there was some printing—upon a visiting card, in fact. The peculiarity is that, whereas none of the acids produced much if any effect on the deposit lying on the white card, where the printed characters were the two last-named acids bleached the deposit, and the printing came out white on a dark ground. The acid was applied in the undiluted state and allowed to act for some minutes, which seem to negative my first idea that the image lying on the printer's ink was thinner, and therefore more easily and quickly penetrated. Can any one suggest an explanation?"

Films of Pure Silver Bromide.—"The inquiry of 'A. W. S.' on this subject, in this column last week, reminds me of some experiments made some years ago, which point to a doubt as to whether pure bromide of silver is amenable to alkaline development. Bromide of silver, like the chloride, is fusible by heat, and I adopted that method of separating the silver from a large quantity of spoilt collodion emulsion, which was first evaporated to dryness, and then burnt in an ordinary crucible and afterwards further heated. The fused bromide of silver was then poured out into an iron plate, forming, when in the fused condition, a deep red liquid, and solidifying into a dirty grey slag having a sonorous ring like metal or porcelain. When broken, it showed a yellow or nearly white fracture like ordinary precipitated bromide, the grey colour being merely superficial, and probably consisting of subbromide or an oxybromide. Out of curiosity, by means of abrasion and otherwise, I removed the greyness from the smooth side of several of these fused pieces, in the dark room, of course, producing a perfectly clean surface of silver bromide, and these were exposed for various periods under a negative or masks cut out in cardboard. But under no condition could I obtain any photographic result on development. With solutions of normal strength there was no action at all, and, if increased sufficiently to cause reduction, it was uniform over the whole surface. The act of fusion may possibly modify or destroy the condition of sensitiveness, but I think it is equally probable that, in the absence of a 'restrainer' in some form, bromide of silver is practically undevelopable.—Syntax.

Panoramic Pictures (To "Lakeland").—"Premising that no such devices can possibly render the subject in correct perspective, the following is a plan which I used to adopt, with fair success, many years ago, and curiously enough it was while on a visit to the Lake district that I first resorted to it as a "scratch" method of securing a panorama. I was using a film camera and the old-fashioned stereo size of plate, $6\frac{3}{4} \times 3\frac{1}{4}$, with lenses of $4\frac{1}{2}$ inches focus, which entirely failed to take in the vast sweep of distance as seen from a point on the Ambleside-road, near Troutbeck Bridge. It occurred to me to gain my end by making two pictures, side by side, on the same plate, using the right-hand lens for the left-hand side of the view, and *vice versâ*, and after one or two failures succeeded fairly well. A pencil line was drawn down the centre of the focussing glass, and a distant mountain peak—I think it was Scaw Fell Pike—in the centre of the composition, was made to coincide with that line, and an exposure made with the right-hand lens. The camera was then swung round until, with the left-hand lens, the same object was brought into the centre line, and the second exposure made. The division in the camera allowed the two pictures to overlap to the extent of about a sixteenth of an inch, and this caused a slight mark down the centre of the compound picture, but beyond this there was not much difficulty in ordinary landscape work if the camera was fairly accurately levelled: but, on subsequent occasions, when working the same plan for architectural work at close quarters, the necessity for an absolute level became very palpable, and the faulty perspective rather pronounced. The same plan can be followed with a single lens and sliding front, the alternate halves of the plate being covered; but, in these days of wide-angle lenses, a better result would accrue from a single exposure, and there would not be the least difficulty in getting a lens of $4\frac{1}{2}$ inches focus, or less, to cover a length of plate greater than that given above."—*Stereoscopic.*

Writing on the same subject, "Narrow Angle" says: "It is very seldom that a really 'panoramic' picture is found that is suitable for camera reproduction, but very good imitations can

often be made by cutting off a lot of the sky and foreground from an ordinary subject, the remnant conveying the idea of having been taken with a very wide-angle lens. I have done many pictures in Scotland, North Wales, and elsewhere, in this manner, using 12 × 10 plates divided in the longest direction so as to make 12 × 5, and lenses from 14 to 24 inches in focus. If the lenses cover the plate well, there is no necessity for any great amount of 'slide' in the front of the camera; all that is necessary is a piece of thin wood or metal to fit in the back frame of the camera inside the focussing glass, and cover one half of the plate: the picture is then brought into the other half by simply tilting the camera.'"

ARTIGUE PAPER (To W. BENINGTON.)—"I do not quite gather whether Mr. Benington desires information concerning the Artigue paper, or whether he refers to coating paper oneself with bichromated gum and pigment. With regard to the former, the paper and sawdust can be obtained, I believe, of Messrs. Adams & Co., in the Charing Cross-road, and if the instructions are followed, especially correct exposure and the temperature of the first tepid water, it is extremely simple to get the most perfect results. The paper should be sensitised by immersion, and not by brushing on the back, and to keep the paper flat in the bath it is a good plan to clip each end of the sheet of paper with a bulldog letter clip, taking them off when the sheet is quite moist, to allow for expansion. By the way, I recommend this plan for rollable celluloid films, it obviates the difficulty of the horrid curling. The surface of the Artigue paper is very tender when damped, and must not be touched with the fingers; care should also be taken to avoid air bubbles in the sensitising bath. With regard to coating oneself, it is necessary to be a good hand at washing colour on paper, and even those who are used to doing so in water-colour painting will find that it is by no means the same thing when one comes to adding a clogging gum to the wash. The object to be aimed at is a deposit of colour held in suspension in just sufficient of the gum, so that each grain of colour is separate, as it were, from its neighbour, and not one on the top of another. It is almost so in Artigue's paper, and, though by hand one cannot hope to arrive at such a result, with practice one can get sufficiently near to it. The coating, therefore, must be of extreme tenuity, so that the grain of the paper shows through. As to the pigments, generally speaking, either dry colours or moist tube colours will do; in as fine a state of division and mixtion as possible. All colours, however, do not answer, without going into the question too fully; for the present, I may say that, for blacks, lamp-black, bone-black, blue-black, and charcoal grey are good—Indian ink is generally gritty. Indian red, or red ochre for reds, the latter tempered with blue for instance. Ordinary sepia is good, but not Vandyke brown. Blanc d'argent or colours which contain a similar substance appear to be impossible. The paper should, of course, be damped before coating. Most Whatman papers are difficult, and I think French drawing papers—not too rough—the best. The mixed bichromate (ten per cent.) and gum as thick as can be made, with lemon juice (or citric acid) in equal quantities, can be put in a dish or saucer and the tube or dry colour added until the requisite tint is obtained and well mixed, then applied with a broad flat brush and sweetened with a softener. It must be admitted that it is not an easy thing to do, and I hope before long to be able to propose an improved method."—ALFRED MASKELL.

Our Editorial Table.

CATALOGUES RECEIVED.

SECOND-HAND list of photographic and scientific sundries, and catalogues of second-hand cameras, &c., photographic lenses, camera lenses and accessories, from Messrs. Morley & Cooper, 70, Upper-street, Islington, N.

THE A B C OF PHOTOGRAPHY.

The London Stereoscopic Co., 106, Regent-street.

THE twenty-fourth edition, of 5000, of this little book has just been issued. To the more elementary part of the work, the value of which we recognised years ago, chapters on photo-micrography, orthochromatics, stereoscopy, and other "advanced" subjects have been added, and the book, evidently the work of a competent authority with a plain and attractive style of writing, therefore appeals to the experienced as well as to the beginner in photography. Many of the Company's well-known productions are described throughout its pages, thus adding to its value as a guide book.

MESSRS. S. B. BOLAS & Co, 11, Ludgate-hill, E.C., send us their price-list of collotype printing. It is got up in the form of a neat booklet, and includes some specimens of collotype printing from the firm's own negatives, both of which are of the highest quality.

News and Notes.

MR. HENRY BALL, chemist, of 121, Lord-street, Southport, informs us that he has a dark room for changing and development free to customers.

ROYAL PHOTOGRAPHIC SOCIETY.—Ordinary Meeting, Tuesday, March 10, 1896, at 12, Hanover-square, at eight p.m. *Notes on Medical Photo-micrography*, by Edmund Roughton, F.R.C.S., and Charles Cosens, M.R.C.S.

THE PHOTOGRAPHIC CLUB.—The next weekly meeting of the Club will be held in the Club-room at Anderton's Hotel, Fleet-street, E.C., at eight o'clock on Wednesday evening, March 11. Mr. T. E. Freshwater, F.R.P.S., F.R.M.S., will lecture upon *Stereoscopic Projection*. Afterwards the lantern will be available for members' lantern slides. Visitors are welcomed by the members.

THE Gem Dry Plate Company, Limited, offer 10*l*. in cash prizes to amateur photographers for quarter and half-plate landscape negatives on Gem Universal or Meteor plates; 10*l*. in cash prizes to professional photographers for cabinet portrait negatives on Gem Portrait plates. Particulars may be had of the Gem Dry Plate Company, Limited, 92, Villiers-road, Willesden-green, London, N.W.

"PROCESS WORK," commencing with the March number, will henceforward be published by Messrs. Percy Lund & Co., Limited, of Bradford and London, in an improved and larger form as a threepenny illustrated monthly, under the title of *Process Work and the Printer*. A distinct section will be devoted to the printing trades, and will give especial attention to the artistic printing of process illustrations.

A SOCIETY FOR STOKE NEWINGTON.—Mr. P. G. Fox, of 18, Rectory-road, Stoke Newington, writes: "I beg to inform you that on the 24th ult. a meeting was held at the Farleigh Hotel, Amhurst-road, N., and a new Society formed, called the Amhurst Photographic Society. The next meeting takes place at the above address on Monday, March 9, at eight o'clock, when the rules will be confirmed and general business conducted. Gentlemen who are interested in photography will be made heartily welcome."

WE are sorry to learn of the death of Mr. Thomas Samuels, the *doyen* of the Chancery Registrar's Department, which took place on March 1, at the age of sixty. For many years he had held the office of churchwarden of Hadley, Barnet, besides that of trustee to most of the local charities, and was formerly a member of the Local Board; but it is principally as a photographer, and the inventor of highly ingenious apparatus connected with photography, that his name will be most familiar to our readers. Mr. Samuels was a member of the Royal and other photographic societies, and designed many improvements in hand cameras and plate-changing appliances.

THE Birmingham Photographic Society's Eleventh Annuual Exhibition and Competition will be held in the Exchange Assembly Rooms, New-street, on May 4, 5, 6, 7, 8, and 9, 1896, opening at 2 p.m., on Monday, May 4, and continuing from 10 a.m. until 10 p.m. each following day. Fourteen silver medals, bronze medals, a silver challenge cup, and other valuable prizes (besides certificates) are offered for competition. There will also be an Exhibition of apparatus, and lantern entertainments will be given each evening. Entry forms and further particulars may be had of the Hon. Secretary, C. J. Fowler, Court Mount, Erdington, Birmingham.

BEVERLEY PHOTOGRAPHIC AND SKETCHING SOCIETY.—The Third public Exhibition of Photographs, Paintings, and Drawings in connexion with this Society will be held in the Assembly Rooms, Beverley, on Easter Monday, April 6, 1896. Numerous silver and bronze medals and certificates will be awarded as prizes. Classes:—Section A (open): 1. Landscape, Seascape, and Architecture; 2. Portraits, Figure Study; 3. Instantaneous Hand-camera Work (six direct prints, on one mount or otherwise); 4. Enlargements; 5. Lantern Slides (set of six); 6. Photographs of the Invisible or New Photography (prints or slides). Section B (members only): 1. Landscape, Seascape, and Architecture; 2. Portraits, Figure Study; 3. Club Excursion Work; 4. Enlargements; 5. Lantern Slides (set of six). All entries and other communications to be addressed to the Hon. Secretary, T. J. Morley, Toll Gavel, Beverley.

BROMLEY CAMERA CLUB.—A General Meeting to formally inaugurate the newly formed Bromley Camera Club took place at the Bromley School of Science and Art on Friday evening, February 21, when there was a fair attendance of local enthusiasts in the art. In the absence of Dr. Scott the chair was occupied by Mr. H. C. Bond, M.A., F.C.S. It was decided that the Club's room be at the Literary Institute, Widmore-road, where there will be a dark room and an enlarging room. Mr. H. C. Bond proposed that Mr. S. B. Webber be the first President of the Club, and the proposal was carried unanimously. The following gentlemen were then elected as a Committee: Messrs. James, A. J. Hicks, Stanley Hawkings, C.E., — Bond, M.A., F.C.S., Dr. Playfair, Dr. Scott, and Dr. Schnitzler. Mr. Grundy was elected as Treasurer. It was proposed that Mr. Godward be elected to fill the position of Secretary, and this was agreed to.

CARDIFF PHOTOGRAPHIC SOCIETY'S EXHIBITION.—The Hon. Secretary writes: "I shall be obliged if you will announce that the Judges at our forthcoming Exhibition will be Messrs. Valentine Blanchard, Fred Hellyer, and B. Gay Wilkinson; also that we have extended the date for entries to the 20th inst."

Patent News.

THE following applications for Patents were made between February 19 and February 26, 1896:—

DEVELOPING.—No. 3603. "Improved Means for Separating Photographic Plates during Development." Communicated by M. Lehmann. F. BISHOP.

PRINTS.—No. 3764. "An Improved Method of Producing Photographic Prints." J. MARTYN.

KINETOSCOPE PHOTOGRAPHS.—No. 3777. "A New or Improved Means for Giving Intermittent Motion to a Strip or Film for Taking or Exhibiting Photographs." H. W. SHORT.

MAGAZINE CAMERAS.—No. 3833. "Improvements in Magazine and other Cameras." W. GRIFFITHS.

AUTOMATIC PHOTOGRAPHIC MACHINE.—No. 3882. "Improvements in Automatic Photographing Machine." Communicated by E. N. Dickerson. Complete specification. H. H. LAKE.

SHUTTERS.—No. 3896. "Improvements in Photographic Shutters and in the Method of Operating the same." Communicated by N. Hansen. Complete specification. G. C. DOWNING.

SCIAGRAPHY.—No. 3902. "Improvements in Sciagraphy or Photography by Means of Röntgen's X rays." S. D. ROWLAND.

LANTERN PLATES.—No. 3949. "Combined Reducing and Enlarging Camera for Making Lantern Plates." R. D. SMITH.

PLATES.—No. 3997. "Improvements in Photographic Plates." I. N. V. BABLON.

PRINTS.—No. 4022. "Improvements in the Method of Producing Combined Photographic and Colour-printed Prints." W. SCHMEER.

VACUUM BULBS.—No. 4023.—"Improvements in the Manufacture of High Vacuum Bulbs for Photographic Purposes." A. W. PORTER.

TRIPOD HEAD.—No. 4037. "An Improved Tripod Head for Hand Cameras." G. HOUGHTON.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

March.	Name of Society.	Subject.
9	Lantern Society	*The New Photography.* H. Snowden Ward, F.R.P.S.
9	North Middlesex	Demonstration of Carbon Printing. The Autotype Company.
9	Richmond	Discussion: *Photography and Art.* Opened by C. H. Davis.
10	Brixton and Clapham	*Concerning Hand Cameras.* W. Fraser.
10	East London	General Discussion.
10	Hackney	*Photography in Unlikely Places; or Notes on Selection of Subjects.* A. Horsley Hinton.
10	Royal Photographic Society	*Notes on Medical Photo-micrography.* Edmund Roughton, F.R.C.S., and Charles Cosens, M.R.C.S.
11	Borough Polytechnic	Flashlight Photography.
11	Croydon Camera Club	Lantern Night.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

FEBRUARY 27,—Mr. R. P. Drage in the chair.

THE INFALLIBLE HAND CAMERA.

Mr. S. HERBERT FRY showed and explained the working of McKellen's Infallible hand camera, the principal feature of which was in the method of changing, which is simple, and not likely to get out of order. At the bottom of each sheath are two projecting pins, which work in two grooves running forward from the back of the camera in connexion with two discs mounted on a shaft, in each of which there is a slot capable of receiving the projecting pins of one sheath. Connected with the shaft is an external key, which, on being revolved as far forward as it will go, deposits the exposed plate at the bottom of the camera, where it is tightly gripped. The key is then turned back, when the pins of the succeeding sheath engage with the discs, and the next plate is ready for exposure. It is a magazine camera, and can be worked with films or plates, or both together. It is fitted with Heywood's direct vision finder, consisting of a sight hole and a wire frame the size of the plate on the top, and has a revolving safety shutter.

THE NEW PHOTOGRAPHY.

Mr. T. E. FRESHWATER prefaced his display of slides on this subject by a few remarks as to his own experiments. He had been aiming to reduce the exposure to a minimum, and likewise the amount of current necessary to excite the X rays in the tube. Messrs. Newton & Co. had been able to make a tube which enabled a much shorter exposure to be given, and he showed two negatives, one of a watch-chain taken with twenty-five seconds' exposure, and another of two fingers with one minute's exposure. The coil used was the smallest yet brought to play in this matter, giving a one-and-a-half-inch spark and the current was obtained from a four-cell Grove battery. With the new tube introduced, the rays can be focussed down on to a given space, and, he believed, with the small coil he used, would cover at least two feet. He could not agree with certain statements that had been made that the plate developed up from the back.

The HON. SECRETARY said the idea was that, if the action is due to fluorescence excited on the glass, the development would be supposed to take place at the back; but, suppose the silver right through was affected, the part that receives the developer first would develop first, although the action may have started from the back.

Mr. FRY inquired as to the relative behaviour of fast and slow plates, and whether Mr. Freshwater had tried films or bromide paper?

Mr. FRESHWATER intended to go into this at an early date, and promised a practical demonstration before the London and Provincial Association.

Mr. GRUNDY said that Mr. Swinton, working with a ten-inch coil with a four-inch spark, had obtained a negative of a coin in one second, and a hand in fifty-five seconds.

The slides shown included some by Messrs. Freshwater, E. D. Bartlett, Coles, Rapson, and Medland.

PHOTOGRAPHIC CLUB.

FEBRUARY 26,—Mr. R. P. Drage in the chair.

A good muster of members was present to hear Mr. HENRY STURMEY's account of a tour in Brittany. The lecturer, who recounted his adventures in an easy and colloquial manner, took his hearers through some most interesting country in Brittany. Starting at St. Malo, Mr. Sturmey described his wanderings and his photographic adventures, the resulting transparencies from which were thrown upon the lantern screen, and evoked from time to time the approbation and approval of those present. The lecturer had evidently started with his photographic eye very wide open, and had kept it so. In the result, an interesting series illustrating the better and lesser known towns in Brittany, antiquities, and fast-disappearing local costumes, the characteristic architecture of the sixteenth century, market towns, and buildings. These, varied with local traditions, marriage, and other countryside customs, made a very interesting evening, for which Mr. Sturmey had the hearty thanks of an attentive audience.

Camera Club.—If any one having the necessary knowledge were to make a list of those subjects in which photography is particularly efficient, he would most surely place near the top of the column

MOUNTAIN SCENERY.

It may be that the white snow against the dark rocks, and the general absence of strong colour has something to do with this; but we must also take into account the marvellous cloud effects, with the alternations of light and shade caused thereby, and the delicate gradations on the sunlit snow which are so wonderfully rendered by the gelatine negative. Snow pictures of the Alps there are in plenty, but they are usually taken in the regular tourist season, and not when the ice king holds full grip on mountain torrent, glacier, and snow-clad peak. The paper read last week at the Camera Club by Mr. J. J. HODDINOTT, giving an illustrated account of three successive winter holidays in the Alps, dealt therefore with such a new phase of the subject that there was an unusually good attendance of members and their friends, and among the latter might be recognised many leading members of the Alpine Club. Mr. Hoddinott's paper might have been divided, like an old-fashioned sermon, into three heads, but we hasten to say that, in no other respect, had it any likeness at all to one of those academical discourses. He spent his first holiday, in 1893, at Chamounix; his second, the year later, at Zermatt: while last winter found him at Grindelwald. At each place his camera was busy, and the various examples of his work, shown by the electric lantern, proved him to be quite an adept at snow scenery. Some moonlight views of Mont Blanc, taken from his hotel window with an exposure averaging forty-five minutes, were really wonderful examples of what can be done in this way. The moon was so nearly vertical that no shifting of shadows was discernible in the photographs, and the snow contrasted very beautifully with the dark sky overhead. In several of the daylight views, Mr. Hoddinott employed a telephoto lens, bringing distant peaks, chalets, and villages into view, which were reduced almost to nothingness in the ordinary photographs which he compared with them. He also showed a number of pictures of gigantic icicles, some having been formed by a mountain torrent, having become solidified by the frost as it leapt over a precipice. It was most interesting to see such good photographs of Alpine scenery taken under such conditions. Even in this country wintry weather brings about sudden storms and showers which are productive of wonderful cloud effects, effects which are seldom seen in summer. So it is in the Alps, as was proved by some of these photographs, which showed cloud banners streaming from the higher peaks, and oceans of vapour crossing

the valleys. A pleasant relief to the mountain scenery was presented by the tobogganning races and skating pictures taken at Grindelwald. Most of these latter pictures were taken in the absence of sunshine with a shutter set at one-seventieth of a second. Any one who wishes to profit by Mr. Hoddinott's example, and has the temerity to brave the winter Alpine blasts, is recommended by him to choose Zermatt as the most favourable centre from which to attack the giant peaks in their wintry jackets.

Croydon Camera Club.—February 26.—There was a full attendance at the Braithwaite Hall, and a programme replete with interesting items. The proceedings commenced with a *tour de force* of unusual attractiveness, the banjo team of ten ladies and gentlemen being photographed with flashlights by Mr. J. Smith, who, having developed the negative, handed it to Mr. G. W. Jenkins, the latter producing therefrom a lantern slide, which was ready to be shown on the screen within forty-five minutes, although not exhibited until, somewhat later, Mr. Bridge finished his lecture. The first portion of the lantern display took the form of

A Trip to Norway,

undertaken by Mr. Bridgman and Mr. F. A. Bridge, the latter of whom acted as lecturer. The views of scenery and people (by turns grand or odd), and the many curious, apt, and humorous remarks by which the pictures were accompanied, thoroughly pleased the large and attentive audience, which, on the termination of the lecture, at the instance of the President (Mr. Hector Maclean, F.R.P.S.), very warmly testified their high appreciation of all they had been shown and told. The second part commenced with a miscellany of members' slides. These were much curtailed in number on account of the flight of time. The scenes at Kimberley and the De Beer's mines were unusually interesting, and the series of slides by Mr. J. T. Sandell of surpassing technical perfection. The following members were represented by views :—Messrs. Maclean, Frost, Holland, Elkin, Bray, J. Noaks, G. W. Jenkins, Underhill, Wreford, Sandell, and J. Smith. In conclusion, Mr. Maclean explained a number of newly made shadowgraphs, kindly lent by Mr. Campbell Swinton ; he also, by the aid of a diagram he had specially prepared, lucidly described the construction and action of a marvellous instrument, which Mr. Swinton only succeeded in perfecting the previous day, called a cryptoscope. The music in the various intervals was of unusual tunefulness and acceptability.

East London Photographic Society.—February 25.—Annual General Meeting, Mr. Walter R. Gould in the chair.—The report pointed to a steady progress, and several pounds are in hand on the past year's working. The election of officers for the ensuing season resulted as follows :—*Vice-Presidents :* Messrs. E. Stone and Walter R. Gould.—*Council :* Messrs. E. Atkinson, Charles Tylee, R. J. Tylee, and F. Uffindell.—*Librarian :* Mr. S. Aldridge.—*Lanternist :* Mr. F. Uffindell.—*Secretary :* H. G. Wallis, 84, High-street, Shoreditch.

Hackney Photographic Society.—February 25, Mr. A. Barker presiding. A paper was read by the Hon. Secretary (Mr. W. Fenton-Jones) on

"Stereoscopic Photography."

He said that many considered this branch of photography to be difficult, but that was a mistake, and it would be found very easy when the few simple working details had been mastered. A special-sized camera was unnecessary, an ordinary half-plate, with square bellows, being quite sufficient. In fact, the speaker preferred the half-plate size, because the camera could be used for both stereoscopic and single-picture work, and plates of that size could be obtained almost anywhere, an important consideration when away on a holiday. For twin-lens work a division was necessary ; but this was very simple, and might consist of a bellows-folding arrangement made to detach when required. Concerning the lenses most suitable for this work, difference of opinion existed, some preferring single combinations, as giving more brilliant results, but he preferred a pair of five-inch doublets, as being generally most suitable for subjects of all kinds. But, whatever lenses were used, they should be accurately paired and, for average work, be mounted with their central axes three inches apart. The speaker preferred the use of a shutter instead of caps, and recommended the Thornton-Pickard. The use of two lenses was not absolutely necessary. As an alternative, two pictures in succession might be taken with one lens by shifting the position of the camera a few inches sideways between the exposures ; or Brown's stereo transmitter might be used with good results. As regards choice of subject for stereoscopic work, almost anything would do, with the exception of distant objects and those with excessive contrasts. Indeed, the avoidance of strong contrasts was one of the most important considerations to be borne in mind, if successful results were expected. With this object in view, exposure must be full, and development weak and kept well under control, the aim being to get a result which would be too flat for a single picture. In printing, undoubtedly the most beautiful results were in the form of transparencies. These could be either with the two pictures on one plate of the correct size (taking care, of course, to transpose them), or be on two separate lantern-sized plates. If the latter method were adopted, it would be found very convenient, for the two plates could be placed with the negative in a half-plate printing frame, printed, and, when finished, transposed, and placed side by side, having previously had a thin slip of their inner edges removed, so that they might be placed together with their centres at from two and three-quarter inches to two and seven-eighth inches distance apart. A cover glass should then be placed over them, and the whole secured by masks and binding strips. The speaker did not recommend the use of ground glass for covers, as it showed the grain too much in the stereoscope. For paper prints a printing paper of smooth surface should be chosen, such as gelatino-chloride. In this connexion he had used the Ilford special paper, and had found it very useful to reduce the contrasts from hard negatives.

North Middlesex Photographic Society.—February 24, Mr. Gosling in the chair.—Mr. G. H. Moss read a paper on the preparation of

Collodio-chloride and Plain Salted Papers.

He coated a sheet of baryta-faced paper with collodion emulsion in a frame like a dish with a hinged bottom, which clamped the paper down and kept it flat. The emulsion was poured on and out at one of the corners, which acted as a spout. After draining, the paper was taken out and hung up to dry. The formula of the emulsion was as follows :—A. Zinc chloride, 12 grains ; tartaric acid, 5 grains ; citric acid, 5 grains. Dissolve in 1½ ounce of methylated sulphuric ether. B. Silver nitrate, 60 grains. Dissolve in 30 minims of distilled water by heat. When dissolved, add 100 minims of pure glycerine and 4 ounces of methylated alcohol. Add 60 grains of gun-cotton (high temperature), well shake, and then add 1½ ounce of ether. By gaslight pour A, a few drops at a time, to B, and well shake. After standing twelve hours and filtered or decanted, it is ready for use. He showed numerous examples of prints by this process, and also of plain salted papers prepared as follows :—Crystallised sodium chloride, 150 grains ; ammonium chloride, 100 grains ; pot, bichromate, 4 grains ; water to 20 ounces. The paper is soaked in this for from three to five minutes and dried, then floated on a bath of silver nitrate, 1 ounce ; citric acid, 150 grains ; water to 8½ ounces. Float for about two minutes. This paper will be found printed in full in The British Journal of Photography for August 9, 1895.

Richmond Camera Club.—On the 17th ult., Mr. Ennis in the chair, Messrs. Braham and Barton, of the Autotype Company, gave a demonstration of carbon or pigment printing, clearly explaining the process, and developing a number of prints, single and double transfer, and transparencies. On the 24th Mr. Ennis again presided, and Mr. L. Taylor lectured on the subject of

Collodio-chloride Paper.

He contrasted the capabilities of the paper with those of gelatino-chloride, finding the former in most respects preferable, while his comparison of the merits of English and foreign collodion papers was not wholly in favour of the former. He showed numerous finished prints, on various brands of paper, showing great variety of tone, and finally toned a number of prints in the sulphocyanide bath.

Birmingham Photographic Society.—February 25, Mr. W. Jones (Vice-President) in the chair, one hundred and fifty members and friends present.—The Walsall Amateur Photographic Society gave a Lantern and Musical Evening. The programme consisted of views taken on excursions to Matlock, Haddon Hall, Tintern Abbey, Chepstow, Dawlish, Teignmouth, Torquay, Cockington, and Brixham. Figure and flower studies—Messrs. W. Meikle, E. A. Day, T. Partridge, and W. A. Hubball. The slides were of a high standard of excellence, and the many effects were much appreciated.

Cleckheaton Photographic Society.—February 19, Mr. D. R. Holdroyd presiding.—Mr. Walter Booth, of Bradford, gave a lecture on

Platinotype Printing.

The lecturer demonstrated the cold-bath process, and developed several papers successfully. He gave formulæ for developing and toning, afterwards toning a number of prints to various shades of sepia, brown, red, green, and blue. He showed some beautiful examples of his own work in platinum, showing its permanency and also that, after all, a photograph may be made truly a work of art.

Derby Photographic Society.—February 18, Mr. A. B. Hamilton in the chair.—Mr. W. I. Chadwick, of Manchester, lectured to a large audience on

Stereoscopic Photography.

The lecture, which was entirely extempore, and illumined with many characteristic flashes of wit, was illustrated by lantern slides of diagrams showing the laws of vision, and by stereoscopic slides, all of which were explained in a lucid and comprehensive manner. Mr. Chadwick laid great stress on the importance of these laws as applied to stereoscopic work, and proved how necessary it was that the broad part, or extra portion of the views, should, in both halves, be next the centre. For want of this knowledge many views were wrongly cut, and the desired effect could not be obtained. He urged upon those present to make transparencies rather than paper prints, as the result was far and away more real and satisfactory. He also gave valuable hints as to an artistic yet easy method of colouring transparencies. At the close of the lecture stereoscopes and slides were handed round to the members.

Liverpool Amateur Photographic Association.—February 27, the President (Mr. J. Sirett Brown) in the chair.—Mr. Charles Hill, Mrs. Bell, Messrs. Ernest Walker and W. Sutherland were elected members. The President then drew attention to the future engagements, and especially to a lecture by Mr. Eadweard Muybridge on March 19 in the City Hall, after which Mr. Charles Sharp, F.L.P., proceeded to deliver his lecture entitled, *The Harvest of the Ubiquitous Eye*, illustrated by 100 lantern slides.

Oxford Camera Club.—February 24.—A lecture was given by Mr. A. Moralt Dillon, of Lincoln College, on

Cilicia and the Taurus Mountains.

It was illustrated by lantern slides from negatives taken by the lecturer, which gave a very good idea of the peculiarities of the country. The parts specially noticed were those round Tarsus, a railway running from Mersina on the coast through Tarsus to Adina. Views were shown of the square at Mersina, with natives eating cucumbers and enjoying the public fountain, as well as of the fine columns still standing of the Argonaut Colony at Soli, and the huge stone coffin of Aratus at Pompeiopolis. A procession of camels was an interesting view, donkeys always going in front to show the camels the way. From Mersina the Cave of the Seven Sleepers was visited. At Tarsus there was abundant material for the camera, among other things the Roman gate, pilgrims returning from Mecca (some of whom strongly objected to being photographed), an old Saracenic building with fine gateway, now used as a school, and the Armenian Cathedral with the stump of a tree said to have been planted by St. Paul. Not far off was the waterfall of the Cidnus, the pool being still pointed out where Alexander the Great caught his fatal chill. A fine mosque at Adina was visited after some difficulty. From thence a trip was made to the famous Cilician gates and a plateau beyond, where both Cyrus and Ibrahim Pacha had made encampments.

Brechin Photographic Association.—February 19.—A set of slides, lent by Messrs. Thomas to show the advantages of using the anti-halation plate, were exhibited. A comparison between the results from an ordinary plate negative and an anti-halation plate negative showed a very striking difference. The whole set of slides were excellent specimens, and were highly commended by the members. Some specimens of members' work were also on exhibition at the same meeting. Platinotype seems to find favour with a few, but printing-out paper is a general favourite, and seems likely to hold its own against all the other papers combined.

Kilmarnock and Ayrshire Photographic Society.—February 15, Mr. J. Mack Wilson, Senbank, Prestwich, presided.—Mr. Thomas Haddow, the representative of the Blair Camera Company, gave a most interesting description of the various articles manufactured by the Company. Among other things, he showed a panoramic camera, which seemed to be a perfect masterpiece of mechanism. It appears not to be a toy, but a practical instrument in the hands of a good worker. Mr. Haddow showed how films were quickly and successfully developed, and at the close gave a description of the new photography. On the motion of Mr. Boyd (Grammar School, Kilmarnock), a very hearty vote of thanks was accorded to Mr. Haddow for his demonstration.

FORTHCOMING EXHIBITIONS.

1896.

March 6 ..... *South London Photographic Society. Hon. Secretary, Charles H. Oakden, 30, Henslowe-road, East Dulwich, S.E.

„ 6 ..... *Cheltenham Amateur Photographic Society. Philip Thomas, College Pharmacy, Cheltenham.

Correspondence.

☛ *Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

NEGATIVE PAPER.

To the EDITORS.

GENTLEMEN,—Allow me to add my mite in favour of negative paper for roll-holders. I have never had such success with celluloid film in spools as with negative paper. My experience has been confined to the Eastman Company's roll-holder negative paper and celluloid film. The negative paper was very rapid, and was very simple to work with. As far as I remember, the "stripping films" of the same Company came out some time afterwards. The paper negatives gave good prints without grain. Rendering them transparent with vaseline or oil quickened the printing, but, with plenty of light and plenty of time, was not necessary.

The Woodbury tissue, Vergara's film (Fröedman's (?) patent), and the celluloid film, all gave hopes for a transparent medium suitable for use in roll-holders; but it seems likely that, up to the present, the negative paper has been the best of all for this purpose.—I am, yours, &c.,

55, Parliament-street, S.W. S. L. DOBIE.

DENSITY IN NEGATIVES.

To the EDITORS.

GENTLEMEN,—In your issue of February 28, we notice a report of some remarks made by Mr. Chapman Jones wherein he is credited with having said: "Messrs. Hurter & Driffield had stated that the density of a negative could not be varied by the time occupied in development; but this he considered was contrary to general experience."

We can hardly believe that Mr. Chapman Jones can have made such a misstatement, and we imagine that a printer's error has probably crept in. May we, however, ask you to allow us to state that we have never said anything of the kind, and that we quite agree with Mr. Chapman Jones that such a statement would be "contrary to general experience."—We are, yours, &c.,

F. HURTER & V. C. DRIFFIELD.

OPERATORS' GRIEVANCES.

To the EDITORS.

GENTLEMEN,—"Aboveboard's" letter on "Operators' Grievances," published in your issue of February 28, I would commend to all employers in the profession. I am afraid they were ashamed to advertise the salary; and, with regard to "keeping specimens," this game will, I am also afraid, never be stopped. The best way is not to send any, or, if any are sent, to draw the pen across, and so render them unserviceable to the "gent" who would like to exhibit them in his show-case.

In your issue of February 21, you also print a long letter, "A Warning to Assistants," exposing what is, without doubt, a great injustice. I am not quite sure that grumbling is a doty, but stating reasonable cause of complaint is a different matter. There is no doubt this cheap firm stands alone in its treatment of assistants, which is the talk of the profession.

In my long experience (some sixteen years), I cannot recall any such treatment. I sympathise with "A Victim" and others in the employ of this firm. In my firm (Curzon & Co., Kensington) we receive the best of treatment, working hours nine till six. We close on all Bank Holidays, and are given three days in the summer, quite a contrast to the cheap firm.

Can any photographer expect to do "a good business" on wet, dull, or foggy days, and does this cheap firm expect to improve matters by bullying their assistants?

"Cosmos," in a recent number of the JOURNAL, asked "does the photographic profession rank with a 'drapers' shop?'" In this case, I should say it does.—I am yours, &c., FAIRPLAY.

London, W.

THE RECENT LIMELIGHT COMPETITION.

To the EDITORS.

GENTLEMEN,—Referring to Mr. Scarborough's last letter, why he declines to meet me in a fair public contest, in which everybody interested can judge for himself the merits of the respective jets, and objects to each party working his own jet, I am at a loss to conceive; and must therefore leave your readers to form their own opinions upon the subject, which, judging from the orders my manufacturers have already received, is highly satisfactory to me.

In conclusion, I can only say my offer to contest in public, contained in your issue of February 21, is still open for Mr. Scarborough's acceptance, failing which, I shall continue, as heretofore, to assert that my jet was the winner of the recent competition, as every one well knows that none but the loser in a contest is first to suggest it should be considered a draw.

Here, so far as I am concerned, this correspondence closes. Thanking you for your kind indulgence,—I am, yours, &c., G. W. GWYER, JUN.

Bourneville, Sneyd Park, Bristol, March 2, 1896.

MR. INGLES ROGERS'S EXPERIMENTS.

To the EDITORS.

GENTLEMEN,—In your issue of Feb. 21, I observed certain remarks on page 117 relative to the so-called eye pictures, and it may interest you to know that, after very careful experiments in this direction, I have absolutely failed to obtain any result whatsoever. I have used ordinary and isochromatic plates of extreme rapidity, and, in order that the retinal image might be as strong as possible, used a sixteen-candle lamp against a dark background as the object to be gazed at.

The trial was made not only by myself, but also by a friend who has considerable power of concentrating his vision, gained by long-continued microscopic work, and, without doubting what Mr. Ingles Rogers reports as to his own experiments, I am bound to say that, so far as my experiments have gone, there has evidently been something lacking. Whether this something is psychological or physiological it is not for me to say.—I am, yours, &c., W. D. BORLAND, F.C.S.

Beavon Lodge, Green Street Green, near Dartford, Kent, February 26, 1896.

Answers to Correspondents.

*** *All matters intended for the text portion of this* JOURNAL, *including queries, must be addressed to* "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 2, *York-street, Covent Garden, London. Inattention to this ensures delay.*

*** *Communications relating to Advertisements and general business affairs should be addressed to Messrs.* HENRY GREENWOOD & Co., 2, *York-street, Covent Garden, London.*

SHUTTERS; LENSES.—CAROLUS. 1. The second shutter named would be the better for your purpose. 2. Yes to both questions.

REMOVAL OF SILVER STAINS.—IGNORAMUS. Messrs. Marion & Co. sell a solution for that purpose.

GAN-GE, G. SCORAH, "JUSTICE," "DORSET," "ZERO," ALEX. GRANT, R. BENNETT, H. COHN, "ONE OF THE RANK AND FILE," and others. Received: in our next.

BROOKS' COLLODION EMULSION.—DOUBTFUL. Yes; Mr. Brooks still supplies his collodio-bromide emulsion. His address is Laurel Villa, Wray-park, Reigate.

DEVELOPER.—THOS. ROGERS. Probably a metol-hydroquinone developer best meets your requirements. Try the formula given on page 849 of the ALMANAC for 1896.

CAMERAS FOR PROCESS WORK.—SELVYT. These are, we believe, supplied, specially made for the purpose, by Messrs. Mawson & Swan, Penrose & Co., and other firms.

ELEMENTARY BOOK ON THE ELECTRICAL PART OF THE NEW PHOTOGRAPHY.—J. R., C. E. PAYNE, OBLIGED, SUBSCRIBER. Such a book is referred to under "Our Editorial Table" last week.

SHOW-CASE.—S. J. W. There is no means of preventing the rose tint of gelatino-chloride paper from fading when put into the show-cases. It is the action of light that discharges the colour—not the atmosphere.

SOLUBILITY OF FERROUS SULPHATE IN ALCOHOL.—R. T. W. says he has tried to dissolve some ferrous sulphate in alcohol, and asks why he failed to do so.—In reply: Ferrous sulphate is, we believe, insoluble in alcohol.

GAS TUBING.—W. SIMONS. If the indiarubber tubing has become soft and lets the gas through, it should be replaced by new for the sake of safety. There is no effectual way of repairing the tubing when it gets in the condition mentioned.

SPOTS ON NEGATIVES.—PHILIP PARSONS. The only cause we can suggest is that your hypo is contaminated with some impurity. Try a fresh sample. The spots cannot be removed without rendering the negative more useless than it is.

COLOURING TROUBLES.—C. C. BATES says: "We should be much obliged if you could inform us whether there is anything used so as to colour Solio prints, as we have tried several things, and not yet been successful?"—See reply to "F. J. G."

STRIPPING NEGATIVES.—C. ALLON. The best way to prepare the glass—wet-collodion process—for stripping the negative from is to rub it well with powdered talc—French chalk. The film will then strip easily when dry. Of course, no substratum must be used.

TRANSPARENT SPOTS ON NEGATIVES.—BEGINNER says: "I send you a negative with small transparent spots on it. Can you tell me the cause?"—The spots are caused (1) either by dust being allowed to settle on the films; or (2) air bubbles in the developing solution. The remedy is obvious.

COLOURING PRINTS.—F. G. writes: "Can you tell me, through the medium of your Answers column, of any varnish sold to prevent water colours running and sinking into the surfsce of P.O.P. gelatine prints?"—We know of no such varnish, but probably, if the prints were sized with a weak parchment size, it would suffice.

CHARGES.—HISTORIC. There are no stated charges for such work. Every photographer fixes his tariff according to his own ideas. We should say, if you make your usual charges for that class of work, and so much in addition for the negatives, say, about as much extra for the negative as you charge for the copying, it will be about right.

SCABS ON NEGATIVES.—W. G. S. (Rangoon). The "scabs" appear to us to be in the nature of fungoid growtha, doubtless accelerated by climatic conditions. The crystalline appearance wss probably caused by the presence of hypo, which could not have been all washed out. Sorry we cannot help you further than to suggest the trial of another brand of plates.

CINEMATOGRAPH.—C. SPURRIER says: "I have been to Marlborough Hall, Regent-street, and seen the wonderful living photographs on the screen. Can you tell me how they are produced? I think I should like to try my hand at producing them."—Messrs. Lumière's cinematograph is described and illustrated in this JOURNAL for February 7 (LANTERN SUPPLEMENT).

BLOCKING OUT SKIES.—NIKO writes: "Will you kindly inform me which is the best medium for colouring or darkening matt varnish for the purpose more particularly of blocking out skies?" &c.—Any of the coal-tar colours, soluble in spirit, may be used for tinting matt varnish; but the best thing for blocking out skies is the black varnish sold for photographic purposes.

LIMELIGHT PICTURES.—"TABLEAUX VIVANTS" asks: "Will you be good enough to give some informstion to guide me in photographing some *tableaux vivants* by limelight, whole-plate size, rapid plates? Whst exposure must I give?"—It is impossible to say, as all will depend upon the power of the limelight, and the distance it is away from the *tableauz*. Better make a trial exposure beforehand.

COLLODIO-CHLORIDE PRINTS.—BEGINNER forwards us some collodio-chloride prints from which portions of the film have been apparently scratched away. He asks the reason.—You have handled the films far too roughly in the washing operations. Collodion films are of a tender nature, and will not stand the comparatively rough treatment to which albumen prints may be subjected with impunity.

ELECTRIC LIGHT.—ELECTRODE. The experience of London photographers is that it is much cheaper to get the current from the mains than to set up an installation to generate it. As a matter of fact, most, if not all, those who hsd gone to the expense of engines and dynamos abandoned them as soon as they could get the current supplied to them. That, we think, answers your queries in a practical way.

RUBBER SOLUTION.—T. BROADE. You ought to meet with no difficulty in making a solution of indiarubber if you use the right kind of rubber. Get some masticated rubber snd dissolve it in benzole; nothing more is needed. You may, perhaps, find it more convenient to get a tin of indiarubber solution at any of the rubber warehouses and thin that down with benzole; it is less trouble than dissolving the rubber, as that takes time.

THE NEW PHOTOGRAPHY.—"X," who states that he is a constant reader of this JOURNAL, and would like to know how to take "photographs" of the bones of the hand, says his knowledge of electricity is so small that he does not know how to proceed. Would we tell him?—"X" may be a constant reader of the JOURNAL, but he is not a careful one, otherwise he would have seen that, in our last number, we had an article giving the information he desires.

PATENT APPLICATION.—SNAP-SHOT writes: "I notice in your JOURNAL that ——— has patented a hand camera with a changing arrangement, the idea of which, I have reason to believe, he has borrowed from me. I distinctly remember mentioning it to him some months ago. How can I find out if this is so?"—Wait until the specification of the patent is published. This will probably be nine months from the date of application. You can then purchase it for eightpence, and may possibly discover that the idea is not yours after all.

LENGTH OF STUDIO.—BEGINNER. A convenient length for a studio is about thirty feet. That allows of the use of lenses of such foci that the camera may be placed at such a distance from the sitter that good and pleasing perspective is secured and the portraits are free from the distortion caused by the camera being too near the subject.

ADDING FIGURES TO GROUPS, SPOTTING.—F. R. W. writes: "1. I have two orders in hand of groups taken by myself, and have to insert another figure from a copy into the groups. Could you kindly tell me the best way to make the insertion? 2. Could you also tell me of a reliable spotting medium for spotting enamelled prints, either before or after enamelling?"—In reply: 1. Space is too limited in this column to give any useful information on this subject. Articles on it will, however, be found on pages 18 and 82 of the volume for last year. 2. Most of the dealers supply colours specially for the purpose.

CAMERA LENS.—E. MOORE asks: "1. What should be essential in a camera 15×12 for all-round work, studio or field, and consider cheapness? 2. And the most suitable 15×12 lens and focus for groups and architectural work."—In reply: 1. It should be strong, and have all necessary movements, *i.e.*, double swing back, reversing frame, rising, falling, and sliding fronts; be preferably of the "square" form. Better study the various forms advertised in the ALMANAC, wherein you will find a camera mentioned that meets your ideas as regards price. 2. One of the rapid rectilinear or anastigmatic type of about sixteen inches focus.

ENLARGING WITHOUT A CONDENSER.—ENLARGER says: "Would you kindly tell me if I could use an incandescent light for enlarging, without a condenser? My idea is to get a box, and cut a hole at one end, and fit the back of my camera (a half-plate one) to it, the negative being placed in the dark slide. The light would be inside the box with a strong reflector behind it. Do you think that this will answer?"—In reply: If our correspondent will place inside a large box a concave reflector with a whitened surface, and an incandescent light on each side of it, and the negative and objective axially thereto, enlarged images may be projected without the interposition of a condenser.

DISTEMPER, COPYRIGHT, VARNISH.—BACKGROUND asks: "1. The way to make distemper for painting backgrounds. I have a plain one that has become spotted through getting damp. 2. Can I register the photograph of a testimonial of which I have enclosed a rough, unfixed copy. The photographs round the testimonial, and also the design for same were done by me? 3. Can you give me recipe for making negative varnish that can be put on with a brush?"—I. Mix together whiting and lamp-black to the tint required with water so as to make a thick cream, then add enough melted double size, of the oil shops, to form a thin, tremulous jelly when cold. It should be applied cold. 2. Certainly you can. 3. Any of the varnishes, the formulæ for which are given in the ALMANAC, can be applied with a brush if desired. But it may be advantsgeous, if they are so applied, to make them a little thicker by using less solvent.

ACID BATHS.—BOHEMIAN says: "Kindly inform me what is the best method to adopt in order to keep the sensitising bath neutral—silver bath, fifty grains to the ounce of water? My gold hath also becomes very acid. What is a good remedy? It is made as follows:—Twenty-five grains of acetate of soda with a grain or two of bicarbonate. I to some extent lessen the acidity of the silver by mixing a little carbonate of soda with ammonia. Also, for the same purpose, I dissolve a small piece of ordinary soda in the gold bath, and then boil and filter. I am doing batches of 300 to 700 printa a day."—We cannot account for the baths getting so acid unless it is from the paper used, in which case there is no preventive except changing the brand of paper. A little bicarbonate of soda shaken up with the silver bath each time it is returned to the bottle after use, will, of course, neutralise the acidity. The same treatment will also neutralise the toning bath.

DARK PRINTS.—H. J. G. TORNOE (Bergen) writes as under: "May I ask your most valuable answers to the following questions: 1. I throw the albumen silver prints, which are too deeply printed, among the silver residue before toning. Is this the right way to act, or can you inform me of an altogether reliable method for reducing them before toning? 2. I have a large number of over-printed albumen silver prints, which are toned and fixed. Will you advise me to reduce them, and what would you prefer for such a reduction, thinking also of the permanence of the prints? 3. Which degree on Warnerke sensitometer do you prefer a gelatine dry plate to have for average landscape work when there is time enough for exposing?"—In reply: 1. The wisest course is followed, and we should advise its continuance. 2. The same applies again. Over-printed pictures are not worth the trouble of redncing, if time, uniformity of tone, &c., are a consideration, as they are with all professionsl photographers. 3. About fifteen or sixteen.

QUICK EXPOSURES.—E. B. says: "Can you inform me how it is possible to take a photograph in one four-hundredth part of a second? I refer to such photographs as one sees of men jumping, &c. With the exposure tables I work by, I find that such a subject in bright sunshine, midday, in June, with extra rapid plate, would require one-sixtieth of a second. Of course this may not be exactly right, but it means more than six times the exposnre mentioned above. I may add that the stop I calculated for is *f*-6. I can only snppose that, under these circumstances, the subject is much under-exposed, and, if so, is it rectified by a long development in a weak developer? If so, what would a long development mean, minutes or hours?"—In reply: We can only say that tolerably well-authenticated exposures of one four-hundredth of a second, and very much less, have been given without producing *very* much under-exposed results. The essentials are a really rapid plate, a good light, large aperture of lens, and a quick-acting shutter. If the exposure is somewhere near the mark, prolonged or abnormal development is by no means imperative. Let our correspondent try the experiment under the conditions stated.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 1871. Vol. XLIII.—MARCH 13, 1896.

Contents.

EX CATHEDRÂ.

We have not yet heard that any of our professional readers have added to their businesses a department for the production of Röntgen photographs, although we have no doubt that, if an enterprising man were to make this kind of work a speciality, he would speedily receive profitable patronage from hospitals, medical men, and others. Within the last few days it has come to our knowledge that innumerable applications for the services of a "new photographer" have been fruitlessly made, and that a desire unquestionably exists to know where a fractured or malformed limb, or a portion of the human frame, can be promptly shadowgraphed. The photographer who, in Central London, and within easy reach of the various hospitals, is first to cater for the patronage of medical men may possibly build up quite a lucrative business in the production of "shadowgraphs."

* * *

We congratulate Alderman Thomas Keig, F.R.A.S., Photographer, Douglas, Isle of Man, on his appointment to the position of first Mayor of the newly incorporated Borough of Douglas. Mr. Keig is, we believe, the oldest-established photographer in the island.

* * *

Mr. R. Bennett, of 19, Brunswick-street, Liverpool, writes: "I am desirous of obtaining information as to photographs of any of the ancient water and wind flour mills existing in various parts of the country. Most of these are sufficiently picturesque to have gained the attention of many a tourist wandering with his camera through the country, and also many a professional photographer. Will you allow me to inquire from your readers as to the whereabouts of any of these mills, as I am anxious to obtain as many photographs of them as possible? These I purpose using (as illustrations of a style of mill which has now passed away) in my *History of British Corn Mills*, which is almost ready for press."

* * *

We learn that one of the attractions of the Leeds meeting of the Photographic Convention of the United Kingdom will be an Exhibition of the photographs arranged by the President-elect, Mr. H. P. Robinson. The National Association of Professional Photographers will attend the meeting. This is as it should be. The Convention deserves to be better supported by professional photographers than has hitherto been the case, and we hope that the gathering next July will show some improvement in this respect.

* * *

The Editor of the *Camera Club Journal* has, it appears, been taken to task by some of his readers, who are dissatisfied with the photographic *pabulum* provided in that monthly publication, and in the last number of which we find the following plaintive retort: "We are sorry to hear that some of our members are complaining of the 'Notes and News' of the past few months. They are said to be 'twaddle,' also extremely ungrammatical, and even 'piffle,' whatever that may be. In explanation—not excuse, please—we would mention that, as it was difficult to make bricks without straw, so is it not easy to find anything especially exciting to write about photographic matters, more especially as there is no rush of offers of assistance; further, a good deal of the 'twaddle' consists of Club matters, which those who are not constantly in the Club may care to know if they take any interest in its existence and welfare."

"As regards the faults in composition, these may be explained by the fact that the last three *Journals* have been edited and written in a train, and a L.B. & S.C. train at that, which is *almost* an excuse as well as an explanation. If only some of the Club wits would contribute to our columns, what a brilliant little paper our *Journal* would be! but they modestly prefer the *rôle* of critics, and demand the bricks while withholding the straw."

* * *

How far these complaints are justified it is not our business to inquire, but we may, perhaps, be permitted to offer our sincere sympathies to the sorely harassed gentleman whose gratuitous labours on behalf of his fellow-clubmen have met by such an unpleasant form of recognition. The new number of the Club's *Journal* contains some interesting papers and discussions which have been already reported in our columns, and the following fanciful description of what is generally supposed to occur when a film of silver bromide is exposed to light transmitted through a lens and then developed. The author is Captain W. de W. Abney, and the passage occurs in a lecture on exposure and development.

* * *

"Supposing we have a substance which is composed of four atoms, two of which are respectable members of atomic society, restricting their oscillations to the very merest movements, while the other two are much more 'fly-away' and exuberant in their spirits, and perform a valse rather than a stately minuet. It is quite conceivable, nay, it is probable, that one of the last-named pair, receiving an impetus from some outside motive power, would increase the circle of his performance to such dimensions that he would quit his original group of dancers, and find himself gyrating amongst some other group in a neighbouring portion of the ball-room; and there he would perhaps find those parties to whom he would join himself performing quite a different kind of step, and he would himself perforce join in it.

* * *

"The original group, when this volatile gentleman had quitted it, would consist of three only; there would be the two sedate ones, whom we may look upon as the chaperons, and the other volatile one, who would be unhappy at the exit of his partner. The former, that is to say, the chaperons, taking heed of the fate of the fourth, would restrain the third and make him more circumspect, and the party would remain as it was. If, however, the outside motive force continued to act upon the unhappy volatile gentleman, it is quite within the bounds of possibility that he, too, would gradually become in better spirits, and would leave those two antiquated old ladies in the corner, and, gradually increasing his bounds, would eventually gyrate off to some other neighbouring group, and the chaperons would now be left alone and inseparable; no outside invitation will move them one from the other.

* * *

"It may, however, happen that the comparatively quiescent group of three are removed from the influence of the outside invitation altogether, and they imagine themselves safe from further casualty to their group. But they may be doomed to disappointment. A party may appear on the scene seeking to make up a new set, and the volatile number three, being but little tempted to stay with the old fogeys, darts away, joins a new combination, and is kept apart from them entirely."

We heartily compliment Captain Abney on the verve and humour he has imported into the consideration of such a normally dry and solemn subject as the disruption of silver haloids by light, and in all seriousness beg to suggest that this lucid, if somewhat startling and unaccustomed, method of appealing to our old friend the meanest (photographic) capacity is one that admits of expansion and wide adoption. We do not know whether the grumbling members of the Club quoted above consider Captain Abney's similes either "piffle" or "twaddle;" they are certainly plain and understandable, which a good many impressive photographic lucubrations that do not fall under the displeasure of the unsparing critics of the Camera Club frequently are not.

* * *

Arrangements are in progress for the delivery, under the auspices of the Affiliation of Photographic Societies, of six lectures on photography with the chromium salts. The lectures are to be delivered on Friday evenings at the rooms of the Royal Photographic Society, 12, Hanover-square. A wide and, in parts, neglected field of photography is embraced by the subject of the lectures, which, we hope, will be well attended. It is to the credit of the Affiliation of Photographic Societies that the two lectures on photogravure, given under its auspices by Mr. Dennison three years ago, gave a marked stimulus to this process.

FINE DEFINITION WITH LENSES AND COARSE GRAIN IN PLATES.

With all the improvements that have been made in gelatine plates, both as regards sensitiveness and general excellence, there is still one quality which seems, to a great extent, to have been ignored or, at least, largely overlooked by plate-makers, namely, the texture of the image the plates yield. In some plates the grain is so coarse that it is very conspicuous even to the naked eye. During the past year or two, however, some manufacturers have given attention to the subject, and are producing plates which have a far finer grain than those of the past; yet there is still room for greater improvement, even in the best of them. It used to be considered, and generally accepted, that extreme rapidity could only be obtained at the expense of coarseness of grain; but great coarseness of grain is not a necessary concomitant of rapidity, for some of the fastest plates we have tried have possessed a remarkably fine grain; though, fine as that grain was, it would not for a moment compare with that of a wet-collodion negative.

Wet collodion cannot, however, be quoted as being of a standard of fineness, as, in this process, the size of the grain will be in a great measure dependent upon the developer used and the condition of the bath, collodion, &c. The finest grain obtainable with wet collodion is with pyrogallic acid developer, a simply iodised collodion, and a neutral bath. Then, when all are in perfect condition—a condition difficult to maintain—the image will have a decided claret tint, and will appear to be perfectly homogeneous, even under considerable magnification. The finest of all photographic grains, however, is that yielded by the albumen process; here the image partakes more of the character of a stain than an actual deposit of silver. Let any one compare one of the old Ferrier stereoscopic slides with a negative on a gelatine plate, and the difference between

the texture of the two will, indeed, be surprising to those not familiar with it. Let us now turn to lenses.

Considerable difference of opinion seems to exist as to whether some of the new forms of lenses—those for which a flat field is claimed—yield the same fine or miscroscopic definition as do some of those of the older forms—the triplet or the doublet, known as the symmetrical, rectilinear, &c. Those who take the negative view are those who work principally with wet collodion for process work where microscopic definition is essential, particularly with the finest ruled screens—150 lines to the inch, for example. This topic was commented upon by that excellent little trade brochure, *Process Work*, a little while back. Those with the opposite opinion work mostly with gelatine plates. Without going further into this subject, there is no question whatever that the new lenses, or at least those by makers of repute, do yield infinitely finer definition than any of the quick plates now in the market will render. Therefore it is manifest that modern plates do not do justice to the optician's skill.

It may be asked, Where, if the plates will not respond to the definition of the lens, is the advantage of the lenses that yield the microscopic definition it is alleged that some of the older forms do, and which is said to be absent in the newer ones? Very little, if any, for general work, even if the case were as affirmed by some, particularly when that little advantage is counterbalanced by important ones in other directions, more especially when the final result is an ordinary paper print. Further: even supposing the plates were capable of the finest rendering of, say, a process screen 150 lines to the inch, the paper would be quite inadequate to its reproduction. It is a noteworthy fact that paper prints often appear quite sharp, though they are made from negatives that are decidedly unsharp, or those of a very coarse and granular nature. The case would be materially different were the prints on glass, say, by the albumen process, for example. We allude to this matter merely to show that the merits of a lens should not be judged of from a paper print, as is frequently done. It is that which has helped the sale of cheap and inferior lenses, so many of which are now in use by amateurs of the modern school.

Many enlargements suffer materially from the granularity of the image in the original, although that may have been taken by the most perfect lens. In speaking of coarseness of grain, only that in rapid, and moderately rapid, plates is under consideration. That in the special photo-mechanical plates and lantern plates is quite a different thing, as it more closely resembles wet collodion in its texture. What is required is as fine a grain in rapid plates as we get in those just referred to. Then we shall be able to avail ourselves to the full of the optician's skill.

Some Further Peculiarities of Glass.—According to Sigmondi, if a small quantity of protoxide of iron be added to glass in the course of manufacture, it so modifies it as to permit plenty of light but very little heat to pass through. But this effect would seem to have been already discounted in practice, for the green colour of ordinary window glass is owing to the presence of iron. When there is an excess of iron in plate glass "metal," for instance, and the colour is objected to—manganese is added to destroy it. If too much manganese be added, the glass has a tendency to become pink or pale purple after much exposure to light.

The Great Star Chart.—Some particulars regarding this great international project, now in course of realisation, were given by the Astronomer Royal at the last meeting of the Royal Astronomical Society. A special staff under Mr. Hollis has been organized for the work, and already 130 of the plates taken have been measured. It is calculated that in a year's time 180 plates can be measured, and 160 reduced. Reckoning the section of the heavens apportioned to Greenwich, 150,000 stars will be examined, and the whole section completed in about six years. If the other observatories work at the same rate, that period will see the completion of the gigantic catalogue of between two and three million stars.

The Röntgen Rays.—The investigations still continue in every quarter, and results in many directions are notified. In last week's *Nature* much space is given to Professor Salvioni's application, Professors Oliver Lodge and Andrew Gray pointing out that the discovery is Röntgen's own, Salvioni having merely applied it. But, upon perusal of the latter's paper, it is evident he claims no originality, for it is plainly said, "In this there is, of course, nothing new which could not have been deduced from the original experiments of Röntgen." The novelty—if, indeed, it is so—consists merely in making use of known facts to design the arrangement. We have thus further evidence of the need of caution in receiving reports through the non-scientific press of any developments of the "new light." Instead of iristoscope, as first announced, Professor Salvioni terms his instrument a cryptoscope. He used sulphide of barium as the fluorescent screen, but says it may with advantage be replaced by the original cyanide of barium and platinum of Röntgen.

Le Bon's Dark Light.—We have already described the results obtained by this experimentalist, and the failure to repeat them experienced by M. d'Arsonval; but it is undoubtedly the case that similar effects have been obtained by others, and at the last sitting of the Paris Academy an explanation was given of the contrary results in different hands. In M. Le Bon's last paper (see *Comptes Rendus*, p. 386), he states that the results are obtained from the light of an ordinary lamp transformed into dark light by its passage through a copper plate. His experiments are performed in duplicate, *i.e.*, a blank half of the plate not subjected to the dark rays is treated simultaneously with one that has been subjected to their influence, so that any effect of so-called stored light is shown to be non-existent. He has been working at this subject for two years, and was gradually able to eliminate all factors tending to prevent the stated results from being produced.

He encloses the plate in a sheet of copper, and finds the dark rays pass through equally well though ten sheets of paper, sufficient to arrest ordinary light, be interposed; the plate develops up just as though no other obstacle intervened. Also discs of iron several centimetres thick failed to arrest the dark light in the slightest degree. We find ourselves, he says, "in presence of a mode of energy which is no longer light, ... neither is it electricity, since electricity in its known form does not produce such effects. Dark light must probably be looked upon as a new force in addition to the small number already known."

Let us now look at the explanation of the contradictory results. We find ourselves in the presence of facts which seem to indicate that we have to deal with a real discovery of possibly great importance. Messrs. Lumière were unable to repeat M. Le Bon's results, and this explanation was given at the succeeding sitting of the Academy (March 2). To put the matter briefly, M. Henry had already found that fluorescent bodies emitted radiations capable of passing through metals, and M. Becquerel described a series of experiments showing the activity of fluorescent bodies. M. d'Arsonval remarked that yellow-green fluorescence gave active, and violet fluorescence inactive, radiations. M. d'Arsonval, in his unsuccessful results, used plain sheets of copper, M. Le Bon covered his copper with glass, that was all the difference. The glass employed by the latter proved to be a kind that gave the yellow-green fluorescence and this seems to be the whole secret. Lead glass was inactive.

THE GAS-CYLINDER REPORT.

The report of the Committee appointed by the late Home Secretary to investigate the conditions under which compressed gas cylinders are tested, filled, and used has been issued. The following are some impressions based upon the conclusions at which the Committee have arrived:—

1. That the safety of properly constructed cylinders filled with compressed gas, by a well-regulated system, has been thoroughly established.

2. That the Committee who took an immense amount of trouble, by investigation and experiment, to arrive at solutions of one or two vexed questions, found the results were of negative nature only.

3. That the strength of cylinders made from suitable material was fully established and more than equal to the strain put upon them in testing, filling, and in use.

4. That 120 atmospheres is a perfectly safe pressure for the recent type of cylinder, made in conformity with the weight test, and properly annealed, the steel used being of a prescribed ductibility.

5. That only two fatal accidents have happened with cylinders containing compressed gas, due to causes that general regulations would have prevented. They are the Bradford and the Fenchurch-street explosions.

6. That the Bradford is put down in the report among those "Explosions probably due to bad cylinders," and the Fenchurch-street under "Explosions of mixed gas or vapour due to improper compressing arrangement."

7. That the other explosions mentioned were "Explosions due to pure carelessness or causes such that no general regulations would have prevented them;" or else with carbonic acid or ammonia cylinders, and so are outside the consideration of lanternists.

8. That the five explosions of pressure gauges or reducing valves attached to gas cylinders are not likely to be added to, now that it is understood that oil should not be used when testing the former or in lubricating the latter, and making joints sound.

9. That the statement in the report, "The limelight is steadier and more manageable than electric light for such purposes" (theatres), will have to be modified when the results obtained at such places as the Adelphi Theatre, the Empire, and many other places, are fully appreciated.

10. That, considering the output of one Company in London was 100,000 cylinders in a year, the number of accidents is very small, and not nearly as many as due to steam; in fact, the report says, "The number of accidents, considering the extent of the trade, has been very small, and the number of fatalities has been small also."

11. That certain lay papers, talking of gunpowder and cordite, and comparing certain quantities of such explosives with compressed mixed gas, is rather apt to disconcert the public unless the reason for making the comparison is fully stated, and that such explosives were used to test the strength of the cylinders.

12. That, when a cylinder stands the explosive force of cordite, equal to three tons to the square inch, without bursting, it shows how strong it is.

13. That the Committee think that cylinders of the new type, and fulfilling the conditions laid down, are quite safe to be carried by railway without being packed or covered. G. R. Baker.

THE PHOTOGRAPHIC OPINIONS OF ULYSSES McGILP.

II.

Where the Amateur Draws the Line.

To lift up amateurs, or such of them as desire to be exalted, above the odious middle-class art, is surely no unnecessary labour. The task is, none the less, an herculean one, for, sad be it to say so, England — middle-class England — is still unsympathetic to pictorial art. Now, unless nurtured by sympathy, the seeds of great possibilities, which are in some few rare beings, fail to germinate, or if they get so far, the seedlings die for want of warmth and light. This indifference of art is common knowledge to photographers, for we all know that nothing is less attractive, as a subject for a lecture, or demonstration at our societies, than that of art. The British amateur will cheerfully dive into the most puzzling intricacies of optics, chemistry, or of fatuous empiricism, but he draws the line at futile, superfluous art.

Miserable Boredom.

I mind me well, how an artist member of a photographic society prepared a charmingly illustrated art lecturette, to be read to his fellow members. Result: no one but the Hon. Sec. turned up. Since the above, a society having ostensibly for its *raison-d'-être* the cult of pictorial art, held an exhibition, and invited a well-known artist-speaker to give an address upon the subject which the society was formed to encourage. The greatest local big-wig was in the chair, supported by the next greatest. Almost as soon as the man of art began to speak, the chairman buried his face in his hands, closed his eyes in abject dejection, and presented a picture of utterly miserable boredom. The other big-wig kind of looked "what ill have I done to be thus punished?" The large assembly of ladies and gentlemen, after listening *for about two minutes*, conversed together with great noise and volubility. As for the artist-lecturer, having shouted himself nearly hoarse, he, in about ten minutes, gave up the useless effort, and was insulted with the usual insincere platitudes.

I need hardly say that the above assemblage was a thoroughly representative middle-class one, and—I am sorry to add—included a not inconsiderable percentage of photographers; of course, neither the upper class nor the lower class would be guilty of such lack of natural courtesy.

Where The Professional Scores.

This, then, the material out of which one has to try and make a first-class amateur photographic picture-taker. Why, it may be asked, confine these remarks to the amateur? Because natural selection will always be the strongest force in moulding the professional. Let me, while the two branches of photographers are being mentioned, warn the amateur that to compete with the professional in his own peculiar province is mere folly. Topographical photography has been, and is, so well done by those who use special appliances, and who are in constant practice, that the amateur's results cannot approach the above. Walk into the first dealer's you come to, and look through his album of local views; then, if you can, try and recall one amateur who has such a collection of his own "topographies,"—it is almost impossible to name a single one. Any how, one—or even two—swallows make no summer.

It is just the same with portraiture. Bergheim and Annan are, I know, amongst us, and I mind me of one or two others who, like Gulliver, tower above the Lilliputians; for all which the amateur may as well confess defeat.

Next favourite is, of course, snap-shotting—a sport which seems to be in a very sickly condition. Most people are nauseated by the unnatural, displeasing, Paul Pry photographs with which the hand camera has flooded the the land. Here, again, that beastly industrious, and conspicuously enterprising person, the professional, has already cut in and forestalled the amateur in what he would, some of these days, no doubt, have secured, to his undying fame.

Imaginative, but Discreet.

From the foregoing, it will be gathered that there is not much choice of subject left to the amateur desirous of photographic distinction. None the less, there remains ample space for his abilities to expand, and no field is at present less completely occupied than that which Dr. Emerson has been for some time quietly delving in.

The field referred to is the ennoblement of the rare and simple. The patient studying of the less vulgar, the less obvious phrases of natural facts, objects, and aspects; their presentment in refined habiliments, spun and woven by the controlling hands of an imaginative, but discreet, artist.

All which may sound difficult to attain, but is not necessarily so. If you are a shire cart horse, why, *certes*, you cannot beat a Donovan in the Derby; but, being built upon the right lines, it needs but training and striving for all to run a good race.

The Praiseworthy Error of Reticence.

And you may read, or examine much and long before you shall find better hints than in *Marsh Leaves*. I do not, of course, approve

everything in it; do not praise those portions of some of the etchings which, personally, I am unable to admire. But, if some seem, in a measure, erroneous, it is that wholesome error, the error of reticence. Every one who mixes much with painters is aware that the chief difficulty with a picture is to know when to leave off. In nearly all cases, at least, as regards all but the first flight of painters, pictures, or portions of them, are carried too far.

Too far for the painter's knowledge, for his manual skill, for the harmonious renderings of his subject, too far for the inclusion of suggestions and mystery, without which pictures are but poor planes of paint.

It is just in his ability to resist the temptations of carrying his pictures too far that Dr. Emerson teaches his fellow-amateurs an invaluable lesson. Looking at most of his etchings, thus *A Waterside Inn*, or *The Lonely Fisher*, one is not filled to satiety with an over-rich slice of nature. The impression is rather comparable to that maybe intangible, but yet exquisitely, delightful pleasure of the Havannah, or the choice Château Lafitte. And gazing there arise musings and imaginings which the stimulated fancy responds to; and instead of dwelling upon blades of grass, and almost each individual hair upon the kine which crop the herbage, we feel the whole sentiment conveyed by the translation of an impression.

Tantrums of Light and Shade.

Just one thing more which the book, *Marsh Leaves* suggests, namely, our leaders would—apart from all question of the comparative merits of sharpness and fuzziness—do well to learn the lesson set them to avoid taking Nature when she is as it were posing for her portrait. We have, I suppose, got beyond the stage where horses are expressly arranged in pools, or droves of cattle or of sheep obviously planted upon given portions of the pasture land; and such-like devices are almost out of date amongst our leaders. None the less are we being constantly plagued with impossible—or, if possible, undesirable—melodramatic and violent presentments of Nature when she is giving herself airs and graces, or flying into tantrums of light and shade.

At such times she is herself bad enough, but our end-of-the-century amateurs usually manage to make matters even worse by "Over-doing Termagant." To such Dr. Emerson administers a needful corrective, one which is withal very pleasant to swallow. His prescription runs somewhat as follows: Take of the every-day, all-year-round scenes and circumstances which surround you; render them without straining or over-reaching, but with your utmost nicety of adoption and adornment, then you may hope to illustrate many unconsidered trifles of pearl and diamond, which are being continually passed by, in order that Exhibition walls may display sensational travesties.

PHOTO-MECHANICAL NOTES.

There have been several pronouncements of late on the theory of the half-tone process which deserve the attention of all thoughtful workers. Most notable, perhaps, was the article of Count Vittorio Turati, in the *Photographische Mittheilungen*, and his later notes in the *Photographische Correspondenz*, on "A New Photo-mechanical Half-tone Principle." I fail to see any thing new in the *principle*, but the effects secured are decidedly novel, and the article has attracted wider attention than it would otherwise probably have done, by reason of the remarkable examples which accompanied it. I venture to say that the author's description of his methods is hardly comprehensible to the majority of those who have read it, and it is very difficult to follow out the principle by the explanations given. I do not suggest that the author has intentionally omitted any essential details, but the description is certainly not applicable to all the examples given. The author says: "The method of working is as follows: Expose the plate first with a very fine central diaphragm, then expose the original almost sufficient with a small, round, central diaphragm, and now close the whites by a short exposure with a diagonal cross $=a$, according to the first law."

The first law is stated to be (1) "the distance of the diaphragm centres from one another." But nothing is particularly said in the article as to the use of more than one opening in the diaphragm, except where it is said, "The only alterations introduced were the distance of the screen and the construction of the diaphragms according to whether single or double projections should make their appearance." Here, however, we get a clue to the author's meaning and method

For an ordinary half-tone, without any abnormal effects, he used the method described above. The small stop gives the shadow dots; the larger one the high lights; then, to produce the joining up, he uses a × stop. The effect of the latter is to produce the overlapping at the corners in the high-light dots, whilst having little effect on the shadows.

For determining the size of the cross, the distance of the centre of two screen openings from one another must be estimated, and each diagonal of the cross must have a proportional length, determined by the extension of the camera. An easy way of determining it without having recourse to calculation is to draw the cross within the round or square diaphragm one would work with in the ordinary way for the half-tone process. The use of a cross diaphragm has been known for a long time previous to the publication of this article, and also the use of large and small diaphragms in the course of one exposure. The formula, too, for mathematically calculating the distance of screen and size of diaphragm is in accordance with the generally accepted pinhole image theory. So far, there is nothing new in principle.

A close examination of the enlargements from Count Turati's negatives shows that he has made considerable use of other shapes of stops, and of more than one aperture in the diaphragm. In some cases I should imagine he has perforated a second smaller aperture towards the margin of the diaphragm, and has given part of the exposure with this, completing the time with a slit aperture of such a length as would join the image of the two apertures where projected in the highest lights of the negative. This slit aperture, and the corresponding round or square apertures, could be disposed vertically or horizontally to the margins of the screen, or could run parallel with the lines, giving different effects in either case. Further variation could be attained by having two slits, one narrower than the other, and inserting them in the lens in different directions, and giving one a longer exposure than the other. An L-shaped stop, cut in the diaphragm in such a position as to connect at its extremities a preceding diaphragm with two openings, has also apparently been used. Still another effect may have been attained by taking a square stop and running out two diagonally opposite corners. An elliptical stop, with its major axis disposed parallel to the lines of the screen, would give a chain-like line of dots. Where a secondary tiny dot appears in the centre of the white squares, the exact method used by the author is rather difficult to determine. I question very much whether it could be attained by a diaphragm with double opening, but have not thought of testing it this way up to time of writing. I know, however, it can be done in cameras having a screen adjustment from the outside, by first exposing with the larger aperture ordinarily used, then putting in a small stop and shifting the screen a slight degree towards the sensitive plate.

The changes which could be rung on the use of diaphragms in this manner are almost illimitable, but the operator who endeavours to repeat Count Turati's results, without entering into the mathematical calculations which the author has laid down, will probably get the reverse effect to that expected, and probably some abnormal appearance which will utterly unfit the negative for any use.

In his second article in the *Correspondenz* the author describes a much simpler method involving no calculation. He recommends an adjustable screen-holder, and focussing the shape of the dot by observation with an eyepiece on a clear glass focussing screen, on which a cross is scratched for the purpose of setting the eyepiece. This I know is a very successful method, and it is really marvellous to note the way in which the dots vary with the distance when a determined shape of diaphragm has been inserted. In many exposures, with various sizes of screens, cameras, and lenses, I have found the observed dot to accurately coincide with the dot developed in the

negative. Moreover, the distance of the screen determined by this focussing is always proportionate to the stop inserted, so that we obtain two factors correct, and the chief point left to consider is the exposure.

In *Das Atelier des Photographen* Dr. G. Aarland has an article on "The Theory of Half-tone Negative-making," in which he emphasises the statement that "up to the present nobody has pointed out that the whole of half-tone work rests on the fact that the full diaphragm aperture acts only in the middle of every screen aperture, whilst at all other points only a corresponding, and frequently very small, part of the diaphragm aperture is actually used."

The answer to that may be given, that nobody with any practical acquaintance with the work would think of making such a statement. It might have passed muster a year or two ago, but it is now so absurd that this author contradicts it with his own formulæ and diagrams. He goes on to say that "the size of the diaphragm must be most accurately adjusted to the size of the screen aperture, to the distance of the sensitive plate from the diaphragm, and to the distance of the screen from the sensitive plate." This is perfectly correct, and is the formula decided upon by all writers on this subject; but, in attempting to explain the practical application of this, he endeavours to show that the lines of the screen stop the marginal rays from the diaphragm, and only allow the central part of the cone of light to pass. If this is the way Dr. Aarland, or his friend Herr Granowski, works, then it is obvious that, in spite of his formula, the diaphragm aperture is too large or the distance of the screen too great, for the accepted practice is to place the screen at that position where it will allow the point of the cone of light, which has for its base the diaphragm opening, to pass through the screen aperture without obstruction. If calculation shows that such a distance would be too close for convenient working, then we must reduce the diaphragm aperture. To work in the way the author has indicated would simply be to waste time by having to prolong the exposure, because a considerable proportion of the effective light would be wasted by being obstructed by the lines of the screen. The deduction that "half-tone negatives are actually formed by over-exposure" is not, therefore, surprising. Yet, later on, the author instances an exposure of "from one to one and a half minute" in "a fair light." We must confess we have never heard of such an exposure being successful in the practice of half-tone work; but then he manages to get his screen as close as $\frac{1}{2}$ mm. to the sensitive plate, which is hardly possible in ordinary practice. The whole article is, in fact, a curious mixture of sound theory and bad practice.

A more recent Continental contribution to the theory of the subject is an article by W. Weissenberger in the *Photographische Correspondenz* for January. Herr Weissenberger is one of the chief operators at the Imperial State Paper Works, St. Petersburg, and therefore speaks from a practical standpoint. He shows by means of diagrams that the geometrical relation between the shape of the stop and the shape of the dot is practical as well as theoretical; and, quite contrary to Dr. Aarland's theory, he emphasises the fact that this geometrical shape is produced by the projection of light rays from the extreme corners and margins of the stop. This writer, however, illustrates the peculiarity that, with the usual forms of stops (square or an equilateral triangle) and the ordinary position of screen lines the diagonal shape is not strictly in accord with the stop, although it is quite easy to see from the diagrams given that the dots follow geometric laws. For instance, triangle stop gives heptagonal or heart-shaped dot; square stop (with screen diagonal) gives octagonal dot; but, if the screen openings were equal in shape and position in relation to the diaphragm, the shape would be geometrically similar, no matter how far the plane of the diaphragm be removed from the plane of the screen.

Continental theorists (with the exception of Herr Weissenberger) seem to scout the idea of diffraction having anything to do with the half-tone dot formation. The experiments of Mr. Max Levy, backed up by Mr. F. E. Ives, ought to convince any waverers on this point. These investigations have shown that at a certain screen distance the "pinhole image" of a small circular diaphragm aperture (giving approximately parallel rays) appears smaller and brighter than the screen aperture itself, while at other distances it becomes diffused, or its centre even darkened.

Mr. Ives (in his article in the *American Annual of Photography*, 1896) says it has been his practice "to expose for the shadows with a small circular diaphragm aperture, the screen distance being such as to give the smallest and brightest image of this aperture upon the sensitive plate, and to expose for the high lights with a diaphragm aperture of several times greater diameter. In this way a sharp, fine dot is always obtained in the shadows, even when the high lights have to be closed up by a supplementary exposure with a large diaphragm aperture. It is evident, then, that, although the modern screen process was brought to its present degree of perfection on the basis of the pinhole image theory (a good working hypothesis), diffraction really plays an important part, actually improving the 'pinhole image,' or injuring or almost destroying it as the conditions are made favourable or unfavourable."

Though so much has been said and written on the theory of the half-tone screen, I do not think that the subject is entirely exhausted, and we may look for further light on this interesting subject, and for discoveries which will greatly influence the future of the half-tone process. To give an instance, hardly anything has been done, viz., in the use of the screen for photographing from life and from still objects. There is an immense field here, and it is not an impossible one to develop, but it will not be by existing methods.

WILLIAM GAMBLE.

UNIFORMITY IN HALF-TONE NEGATIVES.

OFTEN has the embryo half-tone worker sighed for definite information on certain points—the distance of the screen, size of stop or its shape, wet or dry plates, and, no doubt, several other things usually regarded, more or less, in the nature of search—should he purchase or otherwise acquire, in a more or less direct way, any information presumed to be authentic, it may increase his happiness until he fails, and taps a second source, to find that it contradicts all his previous notions, and he tries a third; and, being assured that both previous instructors are quite wrong, his bewilderment is complete.

This difference of opinion amongst process workers is well understood, and it is not uncommon to find operators engaged in the same establishment following widely different courses, and attaining the same end. The writer well remembers being told by Obernetter, at Munich, that, if he required a new hand for his collotype department, and the choice lay between an experienced collotype worker from another establishment and an intelligent but raw youth from the litho press who had never seen a collotype plate, his instant choice would be the untried hand, as the litho printer would, from sheer ignorance, follow blindly the instructions given and example set, and succeed; while the practical man, from another school, would not be content unless he followed, or attempted to follow, his previous experiences, unmindful of different materials, different methods, and different circumstances, and his attempt to "cross" the two was always attended by disaster. In the early days of any process, each man has worked alone, and followed out his own ideas, and a dozen in as many different parts of the country may have as many methods of attaining the same end, each founds his own school, and the old saying with regard to one man's food being poison to another is again exemplified. In nothing more than half-tone is this seen, and there need be no wonder, for where a certain desired modification is required, and there are several ways of doing it, by rule of thumb, as undoubtedly the production of half-tone negative making is mostly done, operators will vary in their opinions and methods.

There are so many factors in half-tone work that rules can only be made to meet individual cases; but the following lines are written under the impression that they will enable any one who will take the trouble to conduct a few experiments to carry out their operations in a much more systematic manner than the writer has yet observed practised in any studio that he is acquainted with. The data given throughout must only be taken as illustrative, and it is not expected that the identical figures will prove of value, except that they may form a starting-point, and in that light they must be regarded.

Let the operator set up three copies, all, say, silver prints by the same process—passable, but varying: the first one rather "flat," or "tender," as artists would describe it; the second one a normal or quite satisfactory print; the third under-exposed and heavy, but all

with equally pure high lights. Having decided upon a distance by which the plate should be separated from the screen—if the latter be 150 lines to the inch, we will say about $\frac{1}{16}$th of an inch—if that is decided upon, stick to it. Having selected the lens to be used, stick to that also. In the interest of uniformity, it is desirable that a uniform light is used, that one may feel that the experiments are as reliable as possible. Let the copying board be at a fixed spot, say, eighteen inches from, not merely the lamp, but the arcs, and note that the craters of the lamps are always in the same relative position. These are suggestions only; but, whatever the exact conditions most convenient or adopted may be, make them hard and fast. Returning to our three prints—and it may be pointed out here that the use of three prints as described may save time in the experiments, as one has three chances of success, and much may be gained by studying the negatives of three copies made at one exposure—place them on the copying board side by side, copy them all together on one plate, and let the copy be the size of the originals, which may, of course, be *cartes* or even less, use a stop of *f*-22, say, and, as a matter of convenience, a circular aperture of iris form, exposing for ten minutes. Having exposed and developed your plate, it may be found that one of your copies has given an ideal negative for half-tone, the high lights just sufficiently closed, and the dots of the shadows of just the correct strength. If such should prove the case with one copy, then *it cannot be so in the others, for the one success will assure two failures.* Presuming it is the central or second copy of which the negative is perfect when examined under the glass, then, in the case of copy No. 1—the flat one—this will be found correct in the high lights, but the dots in the shadows will be found too large from over-exposure, and the negative worthless, while in the No. 3 copy the high lights will also be correct, but the dots generally will be found too weak, as a result of under-exposure. Assuming, as before mentioned, that the negative of No. 2 print is correct, *note the proportion of the stop to the extension of the camera from the lens centre to the ground glass.* The aperture of the stop may be found to be $\frac{1}{20}$th, $\frac{1}{30}$th, $\frac{1}{40}$th, or $\frac{1}{50}$th of the camera extension, or anything else above, below, or between these numbers; whatever it is, note it. Should the camera be extended thirty inches, and the stop used be one inch in diameter, we will express the value of the stop as *e*-30. This will conclude experiment No. 1. And we will now proceed to copy the three prints again, but on this occasion reducing them to half the original size. Be it noted, the only factor we alter is the position of the camera and the necessary reduction of the extension. If we again use stop *f*-20, and again expose for ten minutes, our central copy will be found with the dots too large in the shadows, the first copy will be "bunged up," and No. 3, while better in the shadows, will have the high lights too much closed up, these results following over-exposure. Practical men know how to overcome this, and, if our desire is to secure the central print, the same exposure may be given again by placing the screen nearer the plate, reducing the stop, moving the light to a greater distance, or shortening the exposure; or, if the operator is using two stops, he may increase the time he uses the small stop, and shorten the time of exposure through the larger one: any of these devices may be resorted to, and sometimes more than one is used at once. What the writer believes to be the simplest method, and that easiest calculated, as opposed to guessing, is when the camera is suitably extended for the reduction. Take note of the extension, and with the iris diaphragm *create a stop of exactly the same proportion to the extension as used in the first experiment*, viz., *e*-30, and with that stop give exactly the same time as in your first trial—ten minutes.

Again a further reduction may be tried this time, say to one-fourth, when the camera is again adjusted; again create a stop *e*-30, giving the standard ten minutes' exposure, and on examination the three negatives produced at *e*-30, with the same exposure, will be found identical in their suitability for process and differing only in size. They will require an identical period of time to print, and the same to etch. For all practically identical copies, this stop *e*-30 and ten minutes' exposure will give, irrespective of enlargement or reduction, uniform negatives, and, *if the result is once right, it will always be right.*

Now, returning to our other copies, just as the centre negative has been in each case identically good, so the first and third copies will in each negative appear identically bad. We will deal with the "flat" or first copy. Here we want to increase the contrast, and this may be done on the basis of any of the variations previously mentioned. In our previous experiments we have seen that the high lights were right in this No. 1 copy, but the shadows too heavily dotted; now if we cut down the exposure, but use the same stop *e*-30, it will put right the shadows, but the high lights will suffer and not be sufficiently closed. Therefore we alter the stop by *enlarging it to, say, e*-20, *and shorten the exposure to, say, six minutes.* The high lights may then be found closed up to the required extent and the shadow dots reduced to the exact requirements. Of course, in practice, to ascertain the exact *e* value of the stop and exposure required may need several experiments, but, *once ascertained, they are universal* for similar "flat" copies.

The "hard" or "heavy" copies that need cutting into now remain to be dealt with; we have seen that, exposed under our first condition, the negatives, while correct in the high lights, were too weak in the shadows, and, having retained our three copies all along, we shall observe that, when we corrected our working to suit the "flat" copy, our heavy one became more unsatisfactory in the negative than before, for, while the high lights became nearly solid, the shadows became blanks. Although apparent, we may point out that, if we fall back upon our original stop, *e*-30, and, instead of giving ten minutes, increase it to fifteen, we make a distinct gain in the shadow, but lose on the high lights; and, to meet this case, we must *reduce the stop to, say, e*-40, this will cut up the shadows more, and, by *extending the time, say, to fifteen minutes*, will bring up the high lights to the required density, and, having ascertained once for all the stop *e*-value and time of exposure for heavy copies, this becomes, as before, universal for similar copies.

In actual practice, place your copies in three classes, which will be treated somewhat as follows:—"Flat," *e*-20, exposure six minutes; good copies, *e*-30, exposure ten minutes; "hard," *e*-40, exposure fifteen minutes. It will be found convenient to have marked and numbered upon the side of the tailboard of the camera suitable divisions, numbered from the centre of the lens to the back, and to have a corresponding and proportionate scale engraved on the lens mount, both drawn out from actual measurements, and numbered proportionately to the tailboard.

Having focussed, whatever the scale of reduction or enlargement may be, with regard to the copy, one has then simply to observe what particular number of the scale upon the tailboard the ground glass falls nearest to, and the operator is immediately and infallibly told what stop is required to give a satisfactory result without the slightest calculation. He simply turns his iris to a number corresponding to the position of the ground glass upon the tailboard, which, if the calculations have been made aright, means that the iris aperture is equal to *e*-30 (or whatever proportion of the extension you may find it necessary to adopt). Instead of having three scales for the three grades of copies, adopt the course of using, say, one or two numbers higher on the iris than indicated on the tailboard when the copy is weak, and one or two numbers lower when heavy—the exact difference must be the outcome of your fundamental experiments.

EDWIN C. MIDDLETON.

RONTGEN'S PHOTOGRAPHY OF THE INVISIBLE.

[Journal of the Society of Arts.]

DURING the past month every one has heard of the photographic discovery of Professor Röntgen, of Würzburg. The word photography signifies drawing by the aid of light, and while all are familiar with ordinary photography, in which common daylight or artificial light is employed, it is because Professor Röntgen has not used ordinary light, and because the results he has obtained have, in some respects, been very extraordinary, that his discovery has caused such a considerable sensation throughout the world.

In this connexion it is interesting to ascertain exactly what we mean by the word "light." Every tyro in science is acquainted with the classic experiment of Newton, in which the white light proceeding from the sun, or from an electric lantern, is split up by means of a prism into the familiar colours of the spectrum.

However, the spectrum that is visible to the human eye does not by any means comprise the whole of the radiations that proceed from such a source of light as the sun or the electric arc. At one end of the spectrum, beyond the dark-red portion, there are rays of radiant heat which do not affect the optic nerve, but which can be felt by other nerves of our bodies, and the existence of which is easily made apparent by means of a delicate thermometer. At the other end of the spectrum—at the end of greater refrangibility, as it is called—beyond the extreme violet, there are dark waves called the ultra-violet rays, which, though invisible in themselves, have strong chemical effect upon sensitive photographic films, and can be made actually visible to the eye by means of the fluorescence that they excite in certain substances. For instance, if the spectrum is thrown upon a piece of paper which has been painted with a solution of sulphate of quinine, the violet end is greatly prolonged, and it is thus possible to see much that previously was totally invisible. As is well known, light consists of vibrations of the ether that fills all space. There can be slow vibrations of large wave-length, as it is called, and there can be rapid

vibrations of infinitesimal dimensions. Some of the long waves experimentally demonstrated by Hertz and Oliver Lodge, which, in accordance with Maxwell's electro-magnetic theory, are identical in every particular, except size and frequency, with those with which we see, may be miles in length, and vibrate but a few hundreds of times per second. At the other end of the scale, the length of waves of ultra-violet light can only be measured in millionths of an inch, and their rate of vibrations in billions per second.

The fact is that, without special appliances, the human optic nerve takes cognisance of but a very minute portion of the radiations that proceed from any luminous body; and, though the word "light" in popular phraseology is restricted only to such radiations as affect our eyes, in a more scientific sense it includes much more.

The photography of the invisible presents no novelty. For years astronomers have employed the photographic plate for the purpose, by means of the cumulative effect of long exposure, of recording the existence of stars which, owing to their enormous distance from the earth, are quite invisible to the eye, even through the most powerful telescope. It is also years since Captain Abney succeeded in the very delicate experiment of photographing a kettle of boiling water in a perfectly dark room, by means of infra red heat radiations that proceeded from the kettle itself. Again, photographs of both invisible ends of the spectrum have been common enough in connexion with researches in spectrum analysis.

The radiations employed by Professor Röntgen in his photography appear, however, to differ considerably from any in the spectra of luminous bodies, as also from those produced by Hertz. Indeed, at present it is uncertain whether the Röntgen rays are of the nature of light at all. They have the peculiarity that, unlike light, they appear to be incapable of refraction by a prism or lens, or of anything but very imperfect reflection. Their not being amenable to refraction, at any rate to an appreciable extent, may be explained on the supposition that they consisted of very long waves similar to those of radiant heat; but against this theory we have the fact that they act upon photographic films far more strongly than do the latter, and also that even a delicate thermopile gives no evidence of their producing a rise in temperature. It seems more probable that they more nearly resemble the ultra-violet rays, though here the absence of refraction can only be explained on the supposition that their wave-length is so exceedingly short as to be comparable to the size of the ultimate atoms. It has been suggested that, whereas ordinary light consists of what are known as transverse waves on the ether, waves similar to those existing in the sea, in which a particle of water moves vertically up and down at right angles to the direction in which the wave is travelling, the Röntgen rays consist of longitudinal ether waves more closely resembling the waves of sound, in which a particle of air vibrates backwards and forwards in the same direction that the sound is moving. Or, again, it is conceivable that the Röntgen rays have no resemblance to light, sound, or other wave motion at all, and that they are more nearly akin to the original and abandoned corpuscular theory of Newton, and consist of particles either of very attenuated matter or of the ether itself moving in rectilinear streams at enormous velocities.

(*To be continued.*)

WATKINS' DEVELOPING COMPETITION.

[Report by Alfred Watkins.]

In this report I endeavour to set down the actual results attained by competitors, and not intrude my own opinions or experiences, which are added in parenthesis where explanation seems necessary.

It will be remembered that two halves (A and B) of one exposure were to be developed by different methods. The main conditions were that the corresponding high lights were to be equal in density, and that unexposed strips of the halves should show no fog or equal fog. The results to be judged by prints; and therefore, in speaking of density or gradation, I refer to the evidence of prints from the negatives.

When I speak of "change of gradation." I mean that A and B coincide as regards density in one tone, other tones being unequal. It is obvious that, when all tones in A are denser than all corresponding tones in B, no change of gradation is proved by the prints. I have recorded change of gradation in each case where it occurs, whether the conditions are complied with or not. Seventeen competitors sent in thirty results.

To sum up: Four competitors—Messrs. B. J. Edwards, Ben Edwards, Sterry, and Channon—have shown decided change of gradation without fog. Three out of these used, for the one half, strong (8 grains or over to ounce) pyro developers; in two cases, with much bromide; in one case, Mr. Sterry, with minimum bromide (½ grain to ounce). The fourth competitor (Mr. Ben Edwards) used, for the two halves, pyro developers identical, except that one contained bromide, and the other little or none. (This means of attaining change of gradation is important. I exhibited an exactly similar example at the Photo Club, when Judges' decision was given. It must not be presumed that variations in amount of bromide will always give change, or that it can be done with all plates. It may perhaps be described as developing a slow plate with developer at the verge of fogging point, and it is a question whether this principle was not followed by all four competitors.)

All the four competitors used comparatively slow plates, and three (Mr. Sterry being the exception) stopped development of one-half before lowest tones were out (a procedure which always secures change of gradation).

Messrs. B. J. Edwards and Channon's examples all bear a glossy surface on the strongly developed halves (not the other halves), also sixteen (ammonia carbonate half), but no other examples do.

Mr. Channon's examples (glossy surface halves) all bear a number of spots of metallic silver, quite absent in corresponding halves. (Does not this give a hint of a reducing action with these developers, for reduced negatives have a similar glossy surface? In looking over my own experiments, in which identity of gradation has been secured, in comparing strong with weak developers, I find no instance of a glossy surface. I need scarcely add that I am not doubting the genuineness of Messrs. Edwards and Channon's examples, but think this might give a clue to the abnormal developing action.)

To deal with the remaining competitors, three (228, 203, 45) have shown change of gradation with unequal fog present.

One competitor (23) has secured change by previous soaking in bichromate of potash.

Two competitors (59 and 52) show absolute identity of gradation with different developers.

Two others (35 and 37) only escape identity of gradation by a mere shade, 37 being metol compared with pyro.

Halation.—The power of obviating this by development is proved by Mr. Sterry (the most striking example), and Messrs. Channon and Marriage. The two first prevent halation with strong pyro, the third with the aid of ammonium carbonate. Mr. Sterry proves that bromide is not necessary for this purpose by using only ½ grain to ounce, but he uses *no alkali*, except that which may be in the sulphite of soda.

Detailed Results.

(*The figures indicate grains to ounce.*)

No. 250. B. J. Edwards.—Edwards landscape plate, exposed 2, 4, 8, 16, 32, 64, 128, 256 seconds to candle at three feet. *A*, pyro, 1½; metabisulphite, 1½; carb. soda, 18; bromide, ⅛; appeared one minute, developed four minutes. *B*, pyro, 8; metabisulphite, 8; carb. soda, 76; bromide, 16; appeared three minutes, developed nine minutes. Result: a very decided change of gradation, highest tones, equal, *B* the shortest gradation, no fog, lowest tones all developed out in *A*, but not in *B*.

No. 249, 251. B. J. Edwards.—Conditions and results same as above. (There is no over-exposure in above examples, the highest tone has received no more exposure than the sky in a correctly exposed landscape.)

No. 246. Ben E. Edwards. — Edwards's med. iso. plate, subject, gradations. *A*, Edwards' pyro and potash, three minutes. *B*, as above (used second time) with bromide added, six minutes. Result: decided change of gradation, not so great as 250, *B* the shortest gradation, no fog, lowest tones developed out in *A*, but not in *B*.

No. 54. J. Sterry.—*A*, pyro, 9½; sulphite, 24; bromide, ½; appeared in twenty-five minutes, developed seventy-five minutes. *B*, metol, 3½; bromide, ½; carb. pot., 12; sulphite, 36; image flashed out, developed ninety seconds. Subject: four gradations all in period of over-exposure amounting almost to reversal. Result: marked change of gradation, *B* all tones much alike and buried in halation, *A* free from halation and fair gradation, no fog in either; Cadett ord. plate.

No. 6. J. Sterry.—*A*, pyro, 12; sulphite, 48; bromide, ½; appeared in sixteen minutes, developed forty minutes. *B*, rodinal, 12; sulphite, 48; bromide, ½; appeared thirty-four seconds, developed twelve minutes. Subject: four gradations, full exposure. Result: marked change of gradation, *B* great halation in upper tones, *A* free from halation, no fog in either; Cadett ord. plate.

No. 230. H. J. Channon.—Ilford ord. plate, landscape subject. *A*, pyro, 10; sulphite, 40; bromide, 6; ammonia, 3; appeared in twenty minutes, developed twenty-six minutes. *B*, pyro, 1; sulphite, 4; bromide, ½; ammonia, 2; appeared eighteen seconds, developed 105 seconds. Result: highest lights do not quite match, but there is a marked change of gradation, no fog, slight halation in *B*, none in *A*, both under-developed negatives.

Four other similar examples by same competitor, none matching in high lights, but all showing marked change in gradation. One of them, remarkable for *A*, taking three hours to develop, 6 grains of bromide being added, no more change of gradation in this example than in the others. All Mr. Channon's examples, except one pair, are thin, the lowest tones in *A* not being developed out.

No. 44. W. Ridler.—Four gradations, Ilford Empress plate. *A*, 1 grain pyro soda, with ½ grain bromide at temperature 70°. *B*, 10 grains pyro soda, with 4½ grains bromide at temperature 50°. Result: no change of

gradation shown, all tones in *A* being denser than corresponding in *B*, *A* very yellow image which visually shows change of gradation, but not when tested by printing.

No. 228. C. A. Brightman.—Cadett ord. plates, landscape subject much under-exposed, half second exposure for sky only. *A*, metol. B, pyro ammonia, 1½ grains. Result: density of sky equal, an apparent change of gradation, *A* having foreground detailed out, and in *B* detail is not developed out. *A* slightly fogged, *B* not.

Nos. 252, 253, 254. Same as above, but exposure one, three, and four seconds. Result: no change, all tones slightly denser in *A*, which has slight fog.

No. 255.—Same as above, but exposure five seconds. Result: slight apparent change, but *A* is fogged, not *B*.

No. 58. A. Thickett.—Four gradations, Ilford spec. rapid. *A*, glycin. *B*, eikonogen. Result: no change, every tone of *B* slightly denser than *A*.

No. 60. W. Richardson.—Landscape subject, Ilford iso. plate. *A*, pyro ammonia, 2. *B*, pyro soda, 2. Result: no change, *B* being denser throughout, no fog.

No. 59. W. Richardson.—As above. *A*, pyro soda, I. *B*, pyro ammonia, 1. Result: identity in all gradations, no fog.

No. 16. E. Marriage.—Architectural subject, Edwards's med. iso. *A*, pyro soda with ammonium carb., 3½; bromide, 1. *B*, pyro soda, 2½; bromide, ½. Result: no change of gradation shown, *B* denser in all gradations, slight fog and halation, *A* no fog or halation.

No. 35. Miss Silk.—Interior, Imperial ord. plate. *A*, velox (normal). *B*, velox slightly diluted and 1½ grains bromide. Result, no change. *A*, a shade denser throughout than *B*. No fog.

No. 203. W. Robbie.—Both *A* and *B* badly fogged and thin. Slight change.

No. 204. W. Robbie.—Landscape, Gem Plate. *A*, pyro ammonia. *B*, metol.

No. 205. As above.—*A*, metol followed by ferrous oxalate. *B*, metol. Results of last two no change, all tones shade denser in *A*, but plates too stained for reliable test.

No. 45. G. Cosser.—Four tones, Ilford ord. *A*, pyro ammonia. *B*, pyro soda. Result: both badly fogged; *B*, outrageously so, change of gradation.

No. 23. G. R. Turner.—Ilford iso. med.; scale of tones. *A*, pyro soda, *B*, soak in 3 grain bichromate potash for six minutes, then developed hydroquinone. Result: change of gradation, upper tones equal, no fog. This is, of course, a reduction process, but interesting.

No. 52. O. J. Slater.—Landscape, Ilford ord. *A*, pyro soda, "weak in pyro;" *B*, pyro soda "strong in pyro." Result, absolute identity in all gradations. No fog.

No 231. S. E. Kelf.—Landscape. *A*, pyro soda. *B*, pyro metol. Result; two exceedingly faint negatives of about equal density and gradation, the united density of the skies far less than the fog in unexposed slip of No. 45.

No. 221. G. Wilkes.—Interior, Marion film. *A*, hydroquinone and eikonogen. *B*, Hydroquinone. Result: no change proved. *A* is much denser in high light, but lower tones are also dense. Attempt was made to match the shadows, fog about equal.

No. 22*b*. G. Wilkes.—Four tones, old Carbutt film. *A*, hydroquinone and eikonogen. *B*. hydroquinone. Result; no change. All tones in B denser than corresponding tones in *A*. No fog.

No. 37. G. L. Wood.—Four tones, Paget xxx. *A*, pyro, 2; bromide, ½; carb. soda, 12, in saturated sol. of soda sulphite; appeared in three minutes, developed 12 minutes. *B*, metol, 2; bromide, 2; carb. soda, 24, in saturated sol. soda sulphite; appeared in 1½ minutes, developed 24 minutes. Result: absolute identity in three upper tones, but lower tone of *A* a mere shade the denser. Slight fog in both, a shade the most in *B*. Both halves same colour.

NOTES FROM THE WEST OF SCOTLAND.

For many years a desire has existed among a large number of professionals in the West of Scotland, that some association should be formed, having for its object the prevention of trade abuses and the dealing with many minor matters which so frequently arise affecting the interests of professional photographers.

In the past, several attempts were made to organize such a society, all of which unfortunately, however, proved futile.

We are pleased to note, however, that quite recently such a scheme has taken practical root, and that at a meeting held last week, which was attended by a good number of the professional workers in the West of Scotland, it was decided to form such a society with a membership of masters only. In the meantime Mr. George Bell has kindly consented to act as Secretary, and a meeting will be held at an early date to frame rules and elect office-bearers.

Some misconception seems to exist *re* Glasgow International Exhibitions which are announced, for there are to be two. Readers of The British Journal of Photography must not confound the fixture which has been arranged by the magistrates and town council of the city, and which will be held in Camphill House, situated in the outskirts of the city, with the more important fixture which is to be held in The Fine Art Institute during the months of September and October 1897. The latter will be a very important Exhibition and will include lantern lectures nightly

Mr. William Riddell, late of the firm of Riddell & Rae, St Vincent-street, Glasgow, starts business on his own account at an early date.

Our Editorial Table.

The New Photography.

By A. B. Chatwood. London: Downey & Co., York-street, Covent Garden.

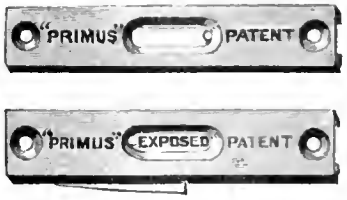
Mr. Chatwood's book consists of four parts, Part I. being devoted to a *résumé* of the work of Röntgen, Gifford, and Swinton with the X rays, and Part II. mainly to Ives's system of photo-chromoscopy. Retinal impressions and "spirit" photography, so called, are treated of in Part III. We note that Mr. Chatwood claims to have succeeded in projecting, from the retina, a developable image on to a sensitive plate years before "Dr." Ingles Rogers published his communications on the same subject in a contemporary. As regards "spirit" photography, Mr. Chatwood shows how fraudulent photographs of "spirits" may be produced, and his attitude towards this much-debated matter is that of one anxious to have opportunities of investigating the alleged phenomena. Anaglyphs are briefly described in Part IV. The book, which sells at 1*s*., has evidently been hastily compiled; but it has been well done, and, aided by some excellent illustrations, is one that will probably make a successful appeal to the general as distinguished from the photographic public.

"Primus" Novelties.

W. Butcher & Son, Blackheath.

Messrs. Butcher, with unceasing enterprise, are early in the field with several useful novelties which are likely to find favour with amateur photographers during the ensuing season.

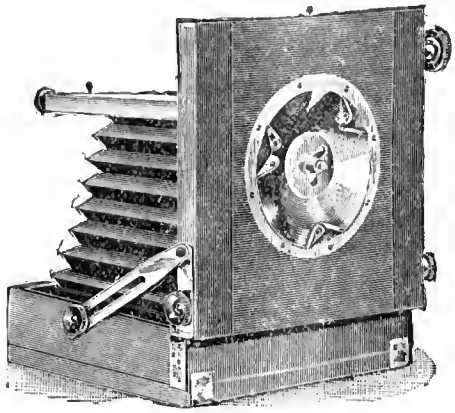
The "Primus" Indicators.—These, which may be fitted to any dark slides, are designed to obviate the risk of double exposure. They are made in brass, with an ivory moving tablet. They are fitted into the end of a dark-slide frame so that the little spring pro-



jects into the rabbet, and are held in position in the frame by the screws. In use:—After the dark slide is filled with plates, push the ivory tablet across the opening, so that the word "exposed" is hid from view, then close the shutter of the slide which holds the tablet in this position; immediately the dark slide is opened in the camera, the tablet slips across the opening and the word "exposed" appears.

The "Primus" Turntable and Universal Tripod Head.—This arrangement supplies all the conveniences of a ball-and-socket joint without working loose or slipping at an awkward moment, and also that of the ordinary turntable. It consists of a metal plate similar to an inverted saucer, which is fixed by means of screws to the base-board of the camera, which must be partially cut away in order to receive it. Working close into this "dish," as it may be termed, is a metal disc attached to the dish by means of a washer of large size

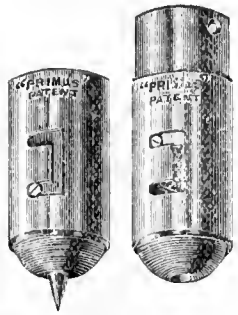
nd a screw. This disc carries the requisite openings into which the egs of the tripod are fitted. A camera fitted with such a tripod



head can be moved about just as thought on a ball and socket joint, with the advantage, that by tightening the binding screw it may be secured rigidly in any position required, and there is no danger of shifting until the screw is released.

THE "PRIMUS" TRIPOD POINT.—This point keeps the stand from slipping on smooth surfaces, and at the same time has no detachable parts to get lost.

It consists of an ordinary point as now used in the field, and a rubber button or half sphere, carried by a brass outer sleeve, which is drawn out over the ordinary point, and is kept in position by a slot



and pin when working upon smooth surfaces. The use of the points prevents the tripod from slipping, no matter how smooth the surface.

The weight scarcely exceeds the ordinary point. They also form a protection to the points when the stand is folded up, preventing their damaging or scratching other articles or the clothing. Being all one, they form part of the stand, and cannot be detached, either intentionally or by accident.

HOW TO ASSIST THE SIGHT.

J. H. Steward, 403 & 457 Strand, W.C.

THIS is a clearly written little pamphlet of some fifty pages, giving, in simple language, a short description of the various defects of vision, with test types and instructions for self-testing. Besides hints on the preservation and improvement of the eyesight, there is a chapter on eyesight in relation to rifle shooting by an old contributor to our columns, Mr. G. R. Baker.

News and Notes.

MR. VALENTINE BLANCHARD has removed to Meadow Lea, Herne-common, near Canterbury.

MR. H. J. BLISS, Grantham, would be glad to hear of any one who has negatives of Moxley Priory or Knaresborough Castle.

MR. WALTER TYLER, of Waterloo-road, will shortly have ready a series of lantern slides, and an accompanying lecture, dealing with Dr. Jameson's Transvaal adventures.

ROYAL PHOTOGRAPHIC SOCIETY. — Photo-mechanical meeting, Tuesday, March 17, at 12, Hanover-square, at eight p.m. *Screens for Process Work* and *A Note on Photogravure*, by Captain Collardon.

NEW CAMERA CLUB FOR SHEERNESS.—At a meeting held at Sheerness on the 7th inst. a club was formed called the "Sheerness Camera Club." The next general meeting will be held on March 21 to consider the rules now being formed by the Committee.

THE PHOTOGRAPHIC CLUB.—The next weekly meeting of the Club will be held in the Club-room at Anderton's Hotel, Fleet-street, E.C., at eight o'clock on Wednesday evening, March 18. Subject, *The New Photography: Notes on the X Rays, with Illustrations by various Workers*, Mr. H. Snowden Ward. Visitors will be welcomed by the members.

WE are sorry to learn of the death of the Rev. H. J. Palmer, M.A., an old and highly esteemed member of the Liverpool Amateur Photographic Association, of which he was formerly Secretary. Mr. Palmer made many contributions to photographic knowledge, which, no doubt, our older readers can recall. He was sixty-one years of age.

THE PHOTOGRAPHERS' BENEVOLENT ASSOCIATION.—The annual general meeting of this Association was called for February 27, but, after waiting for an hour, and insufficient members appearing to form a quorum, it was adjourned to Wednesday, March 4. As there was not a quorum at the adjourned meeting, it was decided to take the business, and ask for confirmation of the Registrar of Friendly Societies. Mr. A. Mackie took the chair; the report and balance sheet (which were sent to all members) were taken as read. A letter from Captain Abney with regard to the proposed transference of the Pension Fund was read, and a resolution was passed that, in order to carry out the suggestion of Captain Abney in his letter of February 15, a new trustee be appointed in his place. Mr. John Spiller was elected to this vacancy. The Committee was re-elected as last year, Mr. E. J. Wall being added to fill a vacancy that had occurred. Unfortunately, the only business of the new Council is to wind up the affairs of the Association, and to arrange for a transfer of its funds to some other body.

Patent News.

THE following applications for Patents were made between February 26 and March 4, 1896:—

CAMERAS.—No. 4110. "Improvements in Photographic Cameras." H. C. PARKINSON.

KINETOSCOPIC PHOTOGRAPHY.—No. 4166. "A New or Improved Means f Exhibiting or displaying to view Consecutive Photographs or Pictures of Moving Objects or Figures." H. W. SHORT.

PHOTOCHROMY.—No. 4244. "A Method of obtaining Light of any desired Colour for the purposes of Chromo photography without the Use of Coloured Glass Screens." C. D. AHRENS.

PHOTOGRAPHIC PLATES.—No. 4286. "Improvements in the Manufacture Photographic Plates of High Sensitiveness to Dark Rays and Radiations." C. O. WEBER.

CAMERA.—No. 4378. "A New and Improved Toy Camera." H. C. BRAUN.

SHUTTERS.—No. 4380. "Improvements in or relating to Shutters for Photographic Apparatus." R. J. S. SIMPSON.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK

March.	Name of Society.	Subject
16	Leeds Photo. Society	*The Old Towns of Holland.* W. J. Warren.
16	North Middlesex	*Enlarged Paper Negatives.* H. Stuart.
16	Richmond	Display of Members' Slides before the Richmond Athenæum at the College Hall.
16	South London	*A Holiday in North Wales.* Messrs. Allen and Fortune
17	Brixton and Clapham	*Collodio-bromide for Transparencies.* F. Goldby.
17	Gospel Oak	General Meeting.
17	Hackney	Annual Dinner.
17	North Surrey	Lantern-slide Competition for the Wolff Prize.
17	Royal Photographic Society	*Screens for Process Work* and *A Note on Photogravure.* Captain Collardon.
18	Borough Polytechnic	*Carbon Printing.* T. F. Bance.
18	Croydon Camera Club	Sixth Annual Dinner.
18	Leytonstone	*A Lens and its Action.* H. P. Hood.
18	Photographic Club	*The New Photography: Notes on the X Rays, with Illustrations by Various Workers.* H. Snowden Ward.
18	Putney	Annual Lantern-slide Competition.
19	Ashton-under-Lyne	Annual Meeting.
19	Bradford	*Phonographs, Kinetoscopes, and the Kinetograph.* Cecil Wray.
19	Darwen	Lantern-slide Making Demonstration. George Latimer.
19	Ealing	*Composition: The Eye Camera and Light.* J. T. Fairs.
19	Liverpool Amateur	*The Motion of the Horse, and other Animals in Nature and in Art.* Eadweard Muybridge.
19	London and Provincial	*Copying.* H. C. Repson.
19	Oldham	Micro-photography.
20	Bromley	*Development* S. B. Webber.
20	Croydon Microscopical	Exhibition of Members' Slides, and of Slides of the New Photography lent by A. A. C. Swinton.
21	Birkenhead Photo. Asso.	Demonstration.

ROYAL PHOTOGRAPHIC SOCIETY.

MARCH 10,—Ordinary Meeting,—The Earl of Crawford, K.T. (Vice-President), in the chair.

Four new members were elected, and seven applications for membership were received.

RADIOGRAPHY.

Mr. T. E. FRESHWATER exhibited a number of radiographs produced by means of Messrs. Newton's X-ray focus tube, with an exposure of two minutes. The tube was designed by Mr. Herbert Jackson, of King's College, and had a concave cathode, the rays from which were reflected from a platinum anode on to the plate and brought to a focus.

Mr. T. BOLAS remarked that Professor Oliver Lodge had pointed out that in the case of the X rays the real radiation was from the anode, and not from the cathode.

Mr. SNOWDEN WARD read a note referring to the construction of vacuum tubes. In designing a vacuum tube for the purposes of radiography, three essentials must be borne in mind—(1) Production of a radiation as intense and as concentrated as possible; (2) Avoidance of necessity for intermission in the exposure; (3) Long total life of the tube. Having referred to the two forms of "fatigue" to which vacuum tubes were subject—temporary fatigue causing the latter portion of the period of exposure to be less efficient than the earlier part, and total exhaustion arising from the slow but constant decrease of the amount of residual gas in a tube when in action—he described a tube which he had worked out, with the assistance of Mr. Robins and Mr. A. C. Cossor, and which, he said, seemed to prevent very perfectly the "fatigue" of the glass, and also to provide the ideal form for giving as large a reservoir as possible of the residual gases. The cathode consisted of a convex plate focussing the cathode rays to a point some little distance outside the tube, so that a comparatively small surface of the glass was bombarded, and the tube revolved on its axis, and the excited portion of the glass was thus constantly changed. Mr. E. J. Wall had suggested that the spot on which the cathode rays fell should be a surface convex to the inside of the tube, by which means the X rays generated in the glass would be focussed to a point situated at the radius of the curve of the tube, and the whole of the active rays would then be practically under control, and could be used to cover with fair exactness any desired space.

Mr. CHARLES COSENS, M.R.C.S., read a paper on

MEDICAL PHOTO-MICROGRAPHY.

He showed the apparatus used by his colleague, Mr. Roughton, and himself, and which he said bore a distinct family likeness to that designed by Mr. Andrew Pringle. As an illuminant, nothing was so satisfactory as the lime-light, and the bull's-eye, or paralleliser was in the form designed by Mr. Nelson, which, when placed in the focus of the lamp, threw almost parallel rays into the condenser. As to the position of the condenser, as long as the cone of rays was not cut down too much for the objective in use, it did not matter where the condenser was placed, provided it was central. With regard to the objective, Zeiss' apochromatic lenses, when used with their corresponding eyepieces, approached nearer to perfection than any others, but excellent results could be obtained with ordinary achromatic lenses. Whichever class of lens was employed, he always used the projection oculars. To the micro-photographer dealing with stained specimens, a knowledge of orthochromatics was absolutely essential. In developing a subject in which detail was the most important point to be brought out, he believed pyro ammonia was the most satisfactory agent, while, for contrast, hydroquinone was preferable.

Mr. EDMUND ROUGHTON, F.R.C.S., explained a series of lantern slides of photo-micrographs of bacilli, and medical and surgical specimens, and after a brief discussion, the usual votes of thanks were passed, and the meeting adjourned.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

MARCH 5,—Mr. R. Beckett in the chair.

In the absence of the Hon. Secretary through indisposition, Mr. FRESHWATER acted in that capacity, and announced the death of Mr. Thomas Samuels, who was well known for his ingenious inventions in the matter of changing appliances, &c.

THE NEW PHOTOGRAPHY.

Mr. FRESHWATER passed round some of his latest shadowgraphs, the sharpness and detail in the tones in which he did not think had been equalled. He did not attribute this success so much to personal skill as to the new focus tube. The subjects included a number of hands and arms containing foreign substances and of more or less surgical interest.

Mr. H. SNOWDEN WARD read a few notes on the new photography. He had hoped to have been able to give in his notes the results of some original observations, but had been prevented from various causes. He had also intended to demonstrate the exhaustion of a tube, but the pump for rapidly doing this had not been delivered, and only a mercury pump for the last stages was available. This was shown at work, however, during the evening. The lecturer quoted abstracts from various sources on the early experiments in connexion with the subject that had been made by Hunt, Richardson, &c. He also described some experiments he had made as to the transparency of the hand to certain strong sources of light, but the outcome was not satisfactory. Lenard had, previous to Röntgen's application, found that the rays from the Crookes' tube were able to penetrate the tube, that they possessed photographic action, and that they passed through certain opaque bodies. Mention was made of a statement by Dr. Shaw to the effect that the cathode rays within the tube had no photographic action, which the lecturer thought very important if correct. With reference to tubes, he considered there was a large field open for both private and business enterprise. Tubes of English and German make of various designs were shown, and the improvements that had been made were pointed out. As regards the appliances, &c., the source of electricity might be the street mains, a dynamo, a battery of suitable form, or accumulators. Mr. Snowden Ward found the latter very convenient, and use was made of them in the present case. A Wimshurst machine had been mentioned, but, up to the present, he had not heard of any success in the results. Wimshurst himself had been devoting some time to the question, but with no better result. He was using a six-inch induction coil, working it at one and a half, which was quite satisfactory. He had produced a plate which would reduce the exposure by one-half.

Mr. FRESHWATER showed the new focus tube, and an exposure was made on one of the member's hands, in which was some broken iron. The position of these pieces was plainly seen with two minutes' exposure, but it was found that less exposure would have sufficed.

Mr. A. HADDON had not heard mention of Hittorf in the paper, who was the first to notice the effect which the cathode rays had on glass.

PHOTOGRAPHIC CLUB.

MARCH 4.—Mr. Frank Haes in the chair.

The Chairman introduced Mr. Walker, of Leeds, to the meeting, and he was welcomed. Mr. Walker is the guiding spirit of the local Committee which has charge of the arrangements for the forthcoming Photographic Convention to be held in his city from July 13 to 18. He is enthusiastic about the success of the meeting, the programme for which is now completed.

About eighty members and friends of the Club were present to hear Mr. Ives's lecture and see his demonstration of

THE PHOTO-CHROMOSCOPE.

The Committee of the Club had arranged with Messrs. Peto & Radford, of 57a, Hatton-garden, to provide the current for an electric arc in the lantern, and this firm are to be congratulated upon the satisfactory nature of their "plant." A fine set of accumulators—in charge of a member of the firm—giving a 20-30 ampère current, and a voltage of 50, worked in an efficient manner throughout the lecture.

Mr. IVES commenced by saying that the photo-chromoscope was an optical instrument which, by the aid of the photographic process, accomplishes for light and colour what the phonograph accomplishes for sound, and the kinetoscope for motion, but with a greater degree of success, and with far simpler and cheaper apparatus. The photo-chromoscope system was based upon the trichromatic theory of vision, and constituted a method of composite colour photography by means of three uncoloured photographic images which constituted a colour record and synthesis by optical superposition of the three images, each illuminated by its appropriate coloured light. The first suggestion of such a method was made by James Clerk Maxwell in a lecture delivered at the Royal Institution, London, May 17, 1861; but Maxwell's lecture appeared to have been totally forgotten for a space of thirty-three years, during which time the idea had been revived by others, and for years was credited to two Frenchmen, Ducos du Hauron and Charles Cros. The process could not have been carried out successfully when first proposed, because the photographic plates of that time were not sufficiently colour-sensitive; but, even after the discovery of means for producing colour-sensitive plates, no real success was achieved, even experimentally, until 1888, when the lecturer pointed out and demonstrated the necessity for using quite different colour filters for the negative process and for optical synthesis. The photographs must be made through colour filters adapted to secure action by definite mixtures of spectrum rays, in accordance with colour-mixture curves similar to those of Maxwell, but the synthesis must be accomplished by means of simple colours only. This fact, although of vital importance, had been totally overlooked by Du Hauron, Cros, Lippmann, and others, who had tried to realise successful processes of composite colour photography. According to the official report of Maxwell's lecture, he, too, made his photographs through the same colour filters that he used for synthesis; but there was reason to suspect that his lecture had been inadequately reported, and that he did not really make this mistake.

By the aid of some beautiful lantern experiments, the lecturer demonstrated the properties of light and colour, and their relation to the photographic process. The means of securing the photo-chromoscope colour record by a single exposure on one sensitive plate was also described, and the images of one of these records were superposed upon the screen by means of a triple lantern-attachment, reproducing in splendid colour a dish of fruit. Permanent colour-print lantern slides made from the photo-chromoscope negatives were also shown, and attention was called to the fact that, although the lecturer had shown such slides years ago, and published the method, which, in important particulars, was all his own, it had recently been claimed as new in France and Germany. It was an interesting, and might prove to be a commercially valuable, process; but the photo-chromoscope system, with its colourless colour records, was of far more practical importance than any other application of the principle, because it was the only one that compared favourably with the ordinary photographic process in simplicity and reliability.

The stereoscopic photo-chromoscope, not much larger than an ordinary hand stereoscope, and remarkable for the simplicity of its construction, was shown to the members at the close of the lecture. Mr. Ives suggested some of the useful purposes which the invention promises to serve, as follows:—In the first place, the works of the old masters can be reproduced by the instrument with every touch and tone of colour depicted as in the original masterpiece. The colour records, occupying little space, can be stored in a small cabinet, or readily sent from place to place for purposes of reference or exchange, affording to the artist opportunities to study at his leisure, and in the quiet of his own studio, the technique of the acknowledged masters of his profession, although the original paintings may not be accessible to him. Decorative work of all kinds can be as faithfully reproduced for the use and study of designers—tapestried hangings, mural paintings, stained-glass windows, furniture, pottery, enamels, &c. Landscapes from all parts of the world, and rare and valuable objects of scientific interest can also be included in the cabinet of colour records. It will even aid in medical diagnosis by acquainting the practitioner with the actual appearance of skin diseases, and their changes from day to day under various conditions, which he has not met with in his own practice. It will not be at all surprising if its value to the science and practice of medicine shall prove to be incomparably greater than that of the

so-called New Photography with the Röntgen rays. It will even prove of considerable value, especially in that country of great distances, America, to many commercial travellers, enabling them readily to show to their customers the exact appearance in colour of objects of merchandise which are too large or too valuable to be economically carried about as samples. It will also probably become an adjunct to every school and college in the world, not only as a beautiful illustration of applied science and a graphic demonstration of the principles of colour vision, but because it will afford, by means of colour records of rare natural history objects and peculiar cabinet specimens, a virtual extension of the school's collection, which may add enormously to its educational value. Its application to portraiture is too obvious to call for comment. Still other useful applications have already been suggested, and new ones, doubtless, will be as it becomes better known.

Brixton and Clapham Camera Club.—An excellent series of slides of Swiss scenery was shown by Mr. W. H. Whittard, after which the slides sent in by members for the Society's March competition were exhibited, and the awards announced by the Judges (Messrs. J. W. Coade (President), E. Dockree, and J. Price), the bronze medal given by the President going to Mr. C. F. Archer, the prize slide being a splendid representation of orchids and lilies in a vase. The second prize (a silver spoon given by Mr. W. Fraser) was won by Mr. R. Fisher, jun., a novice in lantern work, who will probably become a dangerous competitor in future; and the third prize (a salad fork and spoon, also presented by Mr. Fraser) by Mr. J. Gunston, Messrs. W. H. Whittard and A. Bedding being commended by the Judges.

Bromley Camera Club.—March 6, Lantern Evening.—The following members exhibited slides:—Mr. R. W. James, M.I.M.E., Mr. H. Bard, M.A., F.C.S., Mr. E. H. Rogers, Mr. S. B. Webber, and Mr. P. M. Smith. Mr. Stanley Hawkins, C.E., gave a practical demonstration of the working of the New Photography, and a number of slides were put through the lantern, Dr. Scott, B.A., making a few remarks on the use of the New Photography to the medical profession. Dr. Playfair, F.L.S., also spoke, and handed round a number of prints taken by Professor Sylvanus Thompson. The next meeting of the Club will be held on the 20th inst., at the Club's rooms at the Literary Institute, when the subject will be *Development*, by Mr. S. B. Webber.

Camera Club.—March 5, the Earl of Crawford in the chair.—Optical matters were to the fore, and

Two New Lenses

were described by their producers, Mr. Dallmeyer and his colleague, Mr. H. L. Aldis. The first of these instruments seems to have been suggested by Mr. Bergheim, the well-known amateur photographer of Vienna, whose works have of late years attracted much attention at the Pall Mall Exhibitions and elsewhere. We may call to mind one frame in particular, in which three heads of the same woman were shown, illustrating what could be done with a plain subject by arrangement of light, costume, and pose. Mr. Bergheim arrived at that softness of outline and detail in a head which is characteristic of such a painter as Greuze, but he found no lens which would meet his aspirations. Every one knows how a portrait lens, used for a large head, will cause one feature to be sharply defined, whilst its neighbour is fuzzy. In this difficulty with his tools, Mr. Bergheim fortunately met with the help of Mr. Dallmeyer, and the skilled optician soon appreciated what was wanted, and saw how the problem could be solved. The result of his labours is found in the Bergheim-Dallmeyer lens, which will be hailed with joy by all photographers who aspire to artistic portraiture. The lens gives uniform softness, and the only persons who are likely to quarrel with its performance are the retouchers, for they will find their occupation gone. Perfect drawing and modelling of the head and face is practicable with the Bergheim-Dallmeyer lens, but freckles and all other facial blemishes are no longer emphasised on the negative, and therefore need no pencilling out. The other lens is that which has already been introduced to the Royal Photographic Society by its author, Mr. H. L. Aldis, B.A., and it is known as the Dallmeyer Stigmatic. The chief defects in the older types of lenses—that is to say, before the introduction of the Jena glass—curvature of field and astigmatism, are in the new lens almost entirely eliminated. Moreover, it works at *f*-4 over an angle of sixty degrees in a very satisfactory manner, as was indicated by the lantern pictures shown, so that photographers will feel anxious to become better acquainted with its advantages.

Croydon Camera Club.—March 4.—The subject of the evening was

An Introduction to Photo-micrography,

by Mr. J. Packham, F.R.P.S. In the course of his introductory remarks the lecturer said that his knowledge of the subject was due to the tuition and encouragement he had received some years ago from a member of the Croydon Camera Club. He trusted that he in his turn would be the inspirer of other members who at present were unfamiliar with the advantages and beauties which followed the photographing of microscopically small objects. Mr. Packham began his demonstration by showing and explaining the uses of the various appliances needful. The microscope employed was a "Cambridge Model," by H. Crouch. The objective lenses were attached by means of a black-lined tube to the lens of a quarter-plate camera; an ordinary flat-flame paraffin lamp was employed with a condenser; Edwards's isochromatic plates, combined with a yellow screen, placed behind the objective, were advised. With the above the exposure ranges from five seconds to as many minutes. Mr. Packham also explained his method of masking negatives previous to making lantern slides therefrom. Developer used was hydroquinone; pyro soda has also been found of value. At the termination of the demonstrations, about fifty lantern slides of photo-micrographs were thrown upon the screen and explained. Most of them were taken as described in the preceding remarks. Some, however, had been photographed from opaque sections by means of polarised light.

Croydon Microscopical and Natural History Club (Photographic Section).—March 6, Mr. J. H. Baldock in the chair.—Mr. A. Roods, the Hon. Librarian, read a paper on

Presto Paper.

Mr. Roods stated that this paper stood as it were midway between a printing-out paper and a development paper, because it was not absolutely necessary that any visible image should present itself on the paper as it came from the frame; but, at the same time, it often happened that parts of the image could be seen. The paper seemed to be admirably adapted for use by artificial light, and oil lamps, gas, Welsbach, and magnesium ribbon all gave good results. Daylight, on the contrary, appeared to be worse than all, unless very dull and subdued, as with it there was great risk of over-exposure, which was to be avoided, as it tended to produce general fog and blocking up of the shadows. He had found that about twenty minutes to oil or gas was somewhere near correct, while Welsbach required only ten minutes. In the case of magnesium, about six inches at a foot was not far from correct. The paper could also be used for enlarging, and he showed some prints produced in this way. One merit of this paper consisted in the fact that, unlike some other papers of a somewhat similar character, it did not require any preliminary treatment with potassium bromide, which it would be at once seen was a distinct advantage. The developer used by Mr. Roods was hydroquinone, as recommended in the published formula issued by the maker. This worked well and gave satisfactory results. The print received no preliminary washing, neither was washing necessary after development; thus time was saved, as the print was put straight into hypo, but, after fixing, it was necessary to wash for about fifteen minutes before proceeding to tone. The toning bath used by Mr. Roods was the ordinary sulphocyanide bath, and with this he got prints almost black (this appeared to result from the exposure having been somewhat too short), warm brown, and dark brown. If toning was carried too far, an unpleasant slaty colour manifested itself. Mr. Roods had used the combined bath of hypo, sulphocyanide, and gold, but he personally preferred the separate bath, which was, moreover, in his hands, much quicker. After toning, the prints were well washed in the usual way. Mr. Roods developed, fixed, and toned several prints which had been previously exposed to all the before-mentioned sources of light, and obtained some very good results. The Chairman said he had had some experience with this paper, and could in the main support all Mr. Roods had said. He thought the fact that the paper could be used in very dull weather, and by artificial light, were great points in its favour, as it enabled prints to be obtained at any time during the worst winter weather, and also by those who could only find time to work in the evening.

North Middlesex Photographic Society.—March 9, Mr. Mummery (the President) in the chair.—Mr. C. A. Hamilton was unanimously elected a member of the Society. Messrs. Burton and Braham, of the Autotype Company, then proceeded to give a demonstration on

Carbon Printing.

Mr. Braham described the whole process, and emphasised the fact that there was more variety in tones that could be obtained at will by this process than all others. Mr. Burton then developed numerous prints on various supports, from the rough Creswick paper to quite smooth; also some transparencies on glass. In reply to various questions, Mr. Braham said that there was a difficulty in combining clouds with a landscape, and they generally put them in the enlarged negative by hand when it was required in making enlargements.

Putney Photographic Society.—February 26, Dr. W. J. Sheppard in the chair.—There was a good assembly of members and friends to hear a description of

A Visit to Spain,

given by Mr. E. D. Purcell, and illustrated by lantern slides, which included bull-fighting and other Spanish customs, the last one showing two most dangerous weapons of that country—*i.e.*, the stiletto and the ladies' fan. Mr. Purcell's easy way of speaking and humorous remarks added much to the enjoyment of the lecture. Slides by Miss Purcell (who, with Mr. Purcell, are ex-members of this Society) were then thrown on the screen, as were also sets by the following members: Dr. C. Wyman, Messrs. Colebrook, Robertson, Plank, and Wm. Martin (Hon. Secretary).

March 3,—Dr. W. J. Sheppard in the chair. Mr. Francis T. Beeson gave a demonstration on

Retouching Defects in Negatives.

Mr. Beeson, who, at a former meeting, had dealt chiefly with improvement of negatives by chemical means, now confined himself to various modes of treatment by hand or mechanical means, and showed how vastly negatives could be improved by the exercise of a little practice and ordinary care, with a certain amount of patience thrown in. The lecturer recommended the more general use of isochromatic plates with full exposures, as the amount of retouching was often considerably lessened thereby.

Aintree Photographic Society.—March 6, Annual General Meeting, Mr. W. B. Hellon in the chair.—The report pointed to a steady progress, and a substantial balance is in hand on the past year's working. The title of the Society and some of the rules were somewhat modified. The election of officers for the ensuing season resulted as follows:—*Hon. President:* Mr. I. E. Bennett.—*President:* Mr. C. H. Adkins.—*Vice-Presidents:* Messrs. J. R. Jones and W. B. Hellon.—*Council:* Messrs. R. M. Owen, John Watson, W. Lockier, J. Harris, G. Ashley, C. F. Inston, John Wilson, and Dr. Fleetwood.—*Librarian:* Mr. G. H. Jackson.—*Lanternist:* Mr. T. Beer.—*Treasurer:* Mr. W. H. Lloyd.—*Secretary:* Mr. D. J. Neill, 8, Chelsea-road, Aintree.—*Assistant Secretary:* Mr. E. P. Heron. The Liverpool Amateur Photographic Association 1895 prize slides were shown on the screen, as well as a number of Mr. Paul Lange's 1895 frost scenes, which were very much appreciated, also a number of interesting slides kindly lent by Messrs. Archer & Sons, of Lord-street, Liverpool. Several items of music were given by the members, including Miss Dickinson and Messrs. R. M. Owen and John Wilson, the violin solos by the latter being greatly applauded. The Aintree Photographic Society dates from 1894, has its headquarters at the Walton Institute, Sefton-road, close to Preston-road Station (L. and Y. Railway), and meets on the first Friday in each month. President, Mr. C. H. Adkins; Secretary, D. J. Neill, 8, Chelsea-road, Aintree. The subscription is: Members, 5*s.*; Associates, 2*s.* 6*d.* No entrance fee. An Annual Exhibition is held. Total

number of members, fifty-eight. Lantern Exhibitions are held in the winter, and Excursions during the summer months. Its object is to render mutual assistance in all things photographic.

Birmingham Photographic Society.—March 3.—Subject, *Photography of Microscopical Objects*, with practical demonstration in the use of the apparatus by Mr. FRED ILES. After describing the uses of the different movements of the apparatus, and showing his method of focussing by the aid of the eyepiece of a microscope (the objective being uncorrected), the lecturer made several exposures, developing them with quinol developer. The lecture was concluded with a very fine show of stereoscopic micrographs by the aid of the lantern. Many questions were asked and satisfactorily answered.

Leeds Photographic Society.—March 5.—A number of photographic exhibits were examined by the members, and an exceedingly favourable opinion expressed regarding the workmanship and practical utility of the Acme camera, Alpha hand camera, and the Vanneck hand camera. Mr. B. A. BURRELL, F.I.C, then gave a lecture, with experiments and demonstration, entitled,

MORE CHEMICALS USED IN PHOTOGRAPHY.

This lecture dealt with some of the chemicals used in the production of the photographic negative. The fixed alkalies, both in the caustic and carbonated condition, were first noticed, and attention was drawn to the composition of the various forms of sodium carbonate. In making up a developer, washing soda should never be substituted for the anhydrous sodium carbonate without it was so stated in the formulæ, and the carbonates should not be confounded with the bicarbonates. Alum and its hardening effect on the film were described. Mr. Burrell stated that he had lately made some experiments with formalin, using this substance in place of alum. A dilute solution of formalin was found to have a very powerful hardening effect upon the gelatine, quite equal to that produced by the ordinary alum bath, with the advantage that little or no washing, after the formalin bath, was required. The effect of sodium sulphite in preventing stain was demonstrated, and then followed an appeal against the use of the combined alum and fixing bath, and it was shown how the advantage claimed for this bath could be obtained in a way that was free from the evils connected with the mixed alum and hypo. A very dilute solution of permanganate of potash was recommended as an eliminator of hypo. This substance is preferable to peroxide of hydrogen, as it is not so liable to decompose, and can be made of a definite strength, and the colour is an index of the destruction, or otherwise, of the hypo. The Committee elected the following gentlemen as members of the Leeds Photographic Society: Mr. Alderman Scarr, Rev. J. J. Merry, Messrs. Henry Dyson, J. Arnott, George Brunton, J. I. Bain, R. Stockdale, W. S. Braithwaite, R. H. Slade, W. H. Beckworth, F. J. Borland, F. Pindar, J. E. Baines, and H. Illingworth.

Rotherham Photographic Society.—March 3.—Mr. T. A. SCOTTON, of Derby, very successfully demonstrated the subject,

IRON PROCESSES IN RELATION TO COPYING DRAWINGS, &c.

Mr. G. T. M. Rackstraw presided. Mr. Scotton showed the simplicity of the ferro-prussiate method—white lines on a blue ground—the more generally adopted process of blue lines on a white ground, and a plan by means of which the blue lines could be converted into an intense black. With regard to the latter, he explained that the inventor's formula was a secret. The drawback was the number of different baths which had to be used. In copying drawings by photography, he suggested that the negative should have a preliminary bath of gallic acid. For printing, he recommended platinotype paper.

Edinburgh Photographic Society.—February 27, Mr. H. Blanc, A.R.S.A., in the chair.—Mr. J. G. GOODCHILD, F.G.S., F.Y.S., M.B.O.U., delivered a lecture entitled

THE SCOTTISH COAST LINE.

By means of limelight views the lecturer showed how the action of the sea and weather told on the different rocks and contributed to bring about modifications in the coast line, the weather having a great deal more to do with the matter than was generally supposed.

MARCH 4.—Mr. J. C. Oliphant, M.A. (President), in the chair.—Mr. G. BALDWIN BROWN, M.A., Professor of Fine Arts in Edinburgh University, delivered a lecture on

PHOTOGRAPHY AND ART.

Professor Brown held that photographers should not attempt to compete with painters in the matter of picture-making, although, with certain limitations, very artistic work could be produced by the camera. The worker with the camera should rather confine himself to photographing effects which the artist could never hope to draw, such as instantaneous cloud effects, moving water, &c. In Italy of the fifteenth century, or in Germany and Holland of the seventeenth century, photography might have set up as a rival to art, because in those days a great deal more detail was painted than is done at the present time. Studies from the life, Professor Brown said, should not be attempted by photography; they should be left to artists, for the reason that no human figure was perfect enough for the camera, whereas a painter could leave out or add as he pleased. The lecturer strongly depreciated the extensive use of retouching.

Photographic Society of Ireland.—February 27, Mr. Alfred Werner (Vice-President) in the chair.—A lecture entitled

PICTORIAL DUBLIN (OLD AND NEW),

and illustrated by lantern slides, was given by Mr. R. L. STRANGWAYS, M.A., Vice-President. The lecture, which was delivered in excellent style, was one of the best ever given before this Society. There was so much of interest to Dubliners about their city explained throughout that it elicited great attention on the part of the audience, while the good humour and refined fun displayed by Mr. Strangways in his observations when occasions presented themselves—for instance, in his description of the methods of conveyance a few centuries ago, and the evolution of the outside-car, besides his droll remarks on the studies or drawings of ancient Dublin by bygone artists—evoked much merriment. The pictures were well adapted to the lecture, and, in many instances, depicted street life in some of the back streets in various parts of the city.

Correspondence.

TRAILL TAYLOR MEMORIAL LECTURESHIP FUND.

To the EDITORS.

GENTLEMEN,—Several members of the Council of the Photographic Convention of the United Kingdom have been discussing the desirability of making a donation from the funds of the Convention towards the above, considering that the late J. Traill Taylor was virtually one of the founders of the Convention, and that the funds so devoted towards the Memorial Lectureship would, while advancing the general interests of photography, serve to keep well in remembrance the labours and high qualities of our late dear old friend.

It has, however, been represented that such a donation can only be legal by being determined upon by the members of the Convention assembled at the Annual General Meeting, when the matter will be laid before them by the Council at Leeds, next July, it having been arranged that the subscription list is to be kept open for some months longer to allow time for contributions to arrive from America and the colonies towards the Memorial Fund.

May, then, this opportunity be taken of placing the matter also before those societies and individuals throughout the country who have not yet responded to the appeal for funds to found the Lectureship, to many of whom the advice and friendly offices of Mr. Traill Taylor were always available, and who will see that, while the object of having such a series of lectures delivered on photographic matters throughout the country will tend to the great advancement of photography, it will be the best possible means of perpetuating the name and labours of J. Traill Taylor, by keeping his memory green.

Mr. Alexander Mackie, of 3, Upper Baker-street, W., the Hon. Secretary for the Fund, will gladly acknowledge any sum that may be forwarded to him. Apologieing for trespassing on your valuable space,—I am, yours, &c.,

R. P. DRAGE,
Hon. Sec. Photographic Convention of the United Kingdom.

KINETOSCOPY ON THE SCREEN.

To the EDITORS.

GENTLEMEN,—Referring to Mr. G. R. Baker's notes on the projection of moving objects on the screen, I am quite willing to admit that to Messrs. Lumière belongs the credit of being the first in England to show the outside public such figures; but, at the same time, I think it is only fair to myself to point out that I successfully showed such pictures at the Royal Photographic Society on January 14, which antedates Lumière considerably. I think it only fair to point out that I was the first in Europe to *successfully* take photographs suitable for either the kinetoscope or the kinetic lantern (many of my *earlier* successful photographs, not being historical subjects, of course, bear no indisputable date); but it is well known that I successfully photographed the Oxford and Cambridge Boat Race last spring, also the Derby, in which is shown clearing the course, the race, and the rush across the course after the race; further, I took a series of photographs at the opening of the Kiel Canal in June last year. The photographs also of the Boxing Kangaroo, Tom Merry, lightning cartoonist, dancing girls, bears, &c., as well as the magnificent wave picture at Dover, are also mine.

I have gone into this matter at some length, as it came to my knowledge that a certain individual had advertised himself as sole manufacturer of these films, whereas he had no more to do with the taking or making of these films than you, Mr. Editor, have had. Now that projection lanterns are springing up like mushrooms all around, I think that it will be useful to know that Mr. Friese Green holds what is really a master patent; and, as he has arranged with a syndicate to run his apparatus, I should not be at all surprised if he asserts his patent rights. I am informed that his claim is a good one, and so thoroughly am I convinced of his rights that I have already entered into an agreement with him, by which I have secured the right of working under his patent. I confess that I was entirely in ignorance of Mr. Friese Green's work when I designed my apparatus, and, as a matter of fact, the principle on which I work is mechanically different to his, but his claim to passing a series of pictures on an endless band intermittently is original with him, and I have very little doubt but that he will be able to uphold his claim.

It may seem a contradiction for me to claim that I was the first to successfully solve the difficulty in Europe in the face of what I have just written, but it is a fact that with my apparatus I am able to take pictures at almost any speed (I have gone as high as 100 per second) *accurately spaced*, which is the crux on which nearly every one has failed. Mr. Friese Green's pictures were, I believe, accurately spaced, but he did not contemplate such great rapidity as the kinetoscope involved. Apologising for trespassing on your valuable space,—I am, yours, &c.,

March 7, 1896. BIRT ACRES.

PHOTO-CHROMOSCOPES.

To the EDITORS.

GENTLEMEN,—The general tone of Mr. Ives's letter in your last issue but one is somewhat of a surprise to me.

When I described my colour camera in your columns, my sole intention was to give your readers an opportunity of becoming acquainted with my apparatus in the same way as I have explained it before some of the London societies. I had not the slightest intention of entering into a patent wrangle with Mr. Ives or any one else, and I think myself right in supposing that there are more convenient and effective methods of settling patent disputes than piling up statements on assertions in the Correspondence columns of your JOURNAL.

Nevertheless, Mr. Ives's letter, though mainly a repetition of his former assertions, contains such a wide extension of his claims, and so many misleading statements, that I cannot allow it to pass unnoticed.

In the first place, I would ask Mr. Ives whether, when he makes a statement in the press, he expects it to be accepted as the expression of his honest opinion; and, if so, how can he reconcile his present statements and the tone of his last letter with his own words on page 109, "I cannot doubt that he (*i.e.*, myself) conceived the idea independently?"

Again, Mr. Ives states that several important features contained in his specification do not appear in mine until December 19, 1895, some time after descriptions of his apparatus appeared in the London photographic journals. This is a misstatement of facts, as a refereuce to my specification will show. There is not a single important feature shown or described, and absolutely nothing claimed, in my complete specification of December 19, 1895, which does not appear in my provisional of February in that year! Does Mr. Ives, in his anxiety to support the contention that my apparatus is a copy of his own, forget that his English specification was only accepted on January 11 of this year, previous to which it was not accessible to the public, and was not printed until a week or two ago?

As regards the rest of Mr. Ives's dates, and his broad claim to my apparatus, and to be the originator of all my ideas, I can only say that he is perfectly incomprehensible, unless he fondly imagines himself to be invested with the sole right of originating everything in connexion with colour photography.

If Mr. Ives is so conversant with the use of semi-transparent silvered mirrors, *and is able to make them successfully*, as he now states, why has he not utilised them in either of his recent patents, instead of the admittedly incomplete methods he employs?

Touching this, let me quote from this very specification which Mr. Ives holds up as the fountain of all my photo-chromoscopic knowledge. Here, Mr. Ives, after referring *only* to plain glass reflectors, coloured glasses and platinised mirrors, but making no reference to silvered mirrors, says: "Platinised mirrors, although transparent, reflect more light than do plain or coloured glasses, *and would be preferable to the latter if they could be made with perfectly plain surfaces.*" The italics are mine. Surely it is deplorable to see an inventor with the very mirrors he requires, so to say, "up his sleeve," yet failing to take advantage of them! But, truly, one's pity deepens to find this same inventor, in his latest patent of February 21, 1895, which is supposed to be the very acme of photo-chromoscope cameras, for want of his own (?) silvered mirrors, having recourse to wedge-shaped glass reflectors chosen at random from a crate of glass, to fixed focus lenses and a complicated optical system, that he may be able to focus his pictures!

Certainly Mr. Ives is wise in recollecting that instruments exist "with differences of detail only." What constitutes Mr. Ives's patent photo-chromoscopes but an adaptation of the ideas of others—Maxwell Young, Helmholtz, Du Hauron, Collen, &c., "with differences of detail only?"

Finally, let me inform Mr. Ives, that as I consider my apparatus is vastly superior, for the purpose for which I constructed it, to his photo-chromoscope, and as it is solely my own invention, I intend to make and offer it on the market whenever I think fit. Further, if all my ideas are only his, if I have "no standing either in fact or in law," Mr. Ives has now an ample opportunity of putting his claims to the test by opposing the sealing of my patent, and I challenge him to do so.

Such a proceeding will be more to the point, and much more dignified than making misleading statements and random assertions which he cannot prove.—I am, yours, &c.,

B. J. EDWARDS.

The Grove, Hackney, March 9.

THE ROYAL PHOTOGRAPHIC SOCIETY ELECTION.

To the EDITORS.

GENTLEMEN,—As untrue statements, in which my name is freely used, are being publicly made, I ask your permission to state a few facts.

There is no progressive "clique" or party. In the best interests of the R. P. S. and of photography, I wish there was such a party. At present, reforms which are supported by a large majority of the active members can be defeated by a small but organized minority, because the majority is not organized. Members who attended the enthusiastic special general meeting in December need not be reminded how their practically unanimous wishes can be practically disregarded by the Council.

As there is no progressive party, a few of us agreed to prevent the scattering of our own votes, and to ask those members whom we believed to be of the same mind to join us. Hence the "circular," hateful to certain rancorous writers.

It is not true, as has been stated, that we oppose the election of any old member. The candidates we supported for twenty places on the Council were twelve in number: eight retiring members and four new men. The eight blanks left room for *every retiring member of Council who had not stated his determination to refuse re-election*, and I believe that most of us voted for them.

It is not true, as has been stated, that we are opposed to Captain Abney.

Many of us regard Captain Abney as an ideal President, but many of us very strongly object to long-term presidency. Some of us think that see-sawing in two-year terms between two presidents (even though they be such excellent men as Captain Abney and Sir Henry Trueman Wood) is rather a disgrace to the Society. To some of us it looks like a proclamation to the world that the Society has only two men fit to fill the presidential chair. Until quite recently we believed that Captain Abney was strongly with us in this view. Two years ago, when pressed to stand for a third term, he refused, and at the annual general meeting stated that his refusal was a demonstration against the long-term system. Sir Henry Wood similarly stated his belief that two years' presidency was the longest advisable, when refusing to stand again this year. It seems, therefore, unfair to use the fact of our nominating another gentleman than the two above named as a handle to attempt to prejudice Captain Abney against ourselves or our cause.

It is not true, as has been stated, that our "circular" was a failure, and that our views were practically repudiated by the Society. We supported one new man for the Vice-Presidency, and four new men for the Council.

Of the five, four were re-elected, as well as the whole of the retiring members whom we supported. We only supported one man whom the election has not endorsed, and those who have stood year after year unsuccessfully, in face of the solid (so-called) retrograde party and the non-attendant vote swayed by a big nomination list, know what this means. If we *had* opposed any old members, or solidly withheld our support, as their truthless taunts appear to be urging us to do, they might possibly now have been in the position of outsiders.

Now that the election is over, and we cannot be so readily charged with place-hunting, it seems wise to put on record some of the principles which some of us believe must be carried if the Society is to realise its high possibilities. As I understand them, these principles are:—

1. Annual election of a proportion of councillors who have not served in the immediately preceding year.
2. Withholding of the names of nominators from the ballot paper.
3. Holding of Council meetings on evenings other than those of the Society's meetings, so that matters of importance need not be adjourned *sine die*.
4. Long-term presidency to be abolished.

There are many members who are now awaking to the *facts* of the Society's management, and who will not long be content with the mere statement of some of the old hands that all suggestions of reform are the suggestions of self-seekers. They will not permanently be diverted from principles by attacks on those who support the principles. They will not permanently believe that attacks on the long-term system are based on a hatred of Captain Abney or of the few good men who happen to be the oldest members of the Council; and I think that some of the opponents of change would be wise to state and defend their own positions rather than to continue relying on side issues and personalities.

It is not my custom to write over a *nom-de-plume*, but I do so now in deference to the gentlemen who charge any member unfortunate enough to be young and active with being a seeker of self-advertisement. At the same time, you are at liberty to give my name to any one who thinks it is his business to know it. I think that the members of the R. P. S. can carry its reforms without making a "progressive party;" but, if not, the party will be organized and will work in the daylight.—I am, yours, &c.,

RANK AND FILE, F.R.P.S.

THE ARTIGUE PROCESS.

To the EDITORS.

GENTLEMEN,—Some statements in the article signed "Dogberry," published in the last number of your paper, are calculated to mislead the

public as to the qualities of the Artigue and bichromated gum processes. The author has the straightforwardness to begin by telling us that "he is ignorant of the details of the process." This explains, in a way, the strange statements found later on, but it is not a sufficient caution for the general public.

Being well acquainted with both processes, I think it necessary to give on the subject some explanations, warranted, I think, by my experience.

Mr. Dogberry seems to think that the carbon process without transfer, such as is illustrated by the Artigue and bichromated gum processes, can only be used for broad effects, such as enlargements give. If, before writing this statement, he had taken the trouble to examine some Artigue prints taken from a direct negative, such as the Salon pictures of Capitaine Puyo, he would undoubtedly have withheld it; for he would have seen that for correct gradation, and minute detail, no process can give more perfect results than this carbon process without transfer.

As for the bichromated gum process, it can give exactly the same results as the former one, according to the way it is worked. I have obtained with fine colours, thin coating and smooth paper, the most harrowing details. These prints have not been shown at the Salon, simply because I did not like them. It is a matter of taste; but I maintain that it is absolutely certain, and proved, that the Artigue process, and the bichromated gum process, can, *at will*, give what Mr. Dogberry calls a perfect carbon negative—a print in which every separate eyelash, and every individual freckle of the model, is minutely and correctly represented. This is a fact, and it seems to me that the text-books mentioned in Mr. Dogberry's paper have only given us theory.

Asking your indulgence for my Continental English,—I am, yours, &c.,
Paris, March 7, 1896. ROBERT DEMACHY.

I include a bichromated gum print taken from a direct negative on drawing paper, not smooth paper. Is there anything of the scene-painter effect in it?

[There is nothing of the "scene-painter's effect" in the print sent, which is an excellent specimen of the process. We may say that we have had many opportunities of comparing the Artigue prints of Puyo, M. Demachy, and others, with ordinary carbon photographs, and have found it difficult to discover that they lose by the comparison.—EDS.]

COLOUR-RENDERING ON ORDINARY PLATES.

To the EDITORS.

GENTLEMEN,—In reply to "Dogberry," I have *not*, in the written communications he criticises, expressed what is my own opinion, respecting ordinary *versus* orthochromatic plates. Further, I have the highest regard and admiration for the splendid aids to photographic advancement given by many gifted writers and perspicuous *savants*. What I protested against was *rubbish* and *twaddle*. All I can say is that, if "Dogberry" has not met with piles of such stuff, in both text-book, and laboratory, his experience or discernment is decidedly unique. How many thousands of photographic smatterers are there who

> "Know many an amulet as charm,
> That would do neither good nor harm,"

and go about proclaiming, with test tube or goose quill, that their trash is as good as gold.

I cannot here, or will not, enter into the whole question raised by Mr. White, but in deference to your wishes, expressed last week in an editorial paragraph, I will ask Mr. White to hasten the publication of the substance of his communication to the Croyden Camera Club. Meanwhile, those interested can profitably occupy themselves with Mr. Sandell's challenge.

Moreover, I have reason to hope that, in the course of a few weeks, a third member of the Croyden Camera Club will make a novel and important communication to the Club, which has a direct bearing on the subject under discussion.—I am, yours, &c., HECTOR MACLEAN.
Croydon, March 7, 1896.

To the EDITORS.

GENTLEMEN,—Pressure of work prevented me from replying to Mr. Sandell's letter last week. I regret that I cannot consent to meet Mr. Sandell, as he totally ignores the two main points of my challenge; and, further, it was my intention, in challenging Mr. White, to uphold a well-known principle, and not to advertise any particular make of plate, which seems to be Mr. Sandell's idea.—I am, yours, &c., E. J. WALL.

SHADOW PHOTOGRAPHY.

To the EDITORS.

GENTLEMEN,—In reading the letters in your JOURNAL bearing on the X rays, I have been surprised that none of your readers have tried the plan mentioned at the Academy of Sciences in Paris by M. Le Bon and M. Murat. Having had a breakdown with a Crookes' tube, and being in the country, I thought I would try their plan, as it required no apparatus, and was discredited when received. It is, nevertheless, a fact that shadow photographs can be taken with or without light, and either lamp light, magnesium light, or daylight, answers.

I have used some scores of plates, and have only failed when not knowing the exposure. Without light all night in the dark room was sufficient, but the articles must be taken from the light first; if taken from the pocket in the dark room, I failed. With a petroleum lamp the exposure was two hours; with magnesium, thirty-six inches had to be burned; with sunlight, forty minutes were sufficient. Slow plates all. In all the experiments the articles were protected as follows: The plate was put in an Ilford plate box, with coins, &c., on top, the lid put on, and then it was wrapped round with a ferrotype plate, and underneath a piece of tea lead, this being bent round the head and sides, and pressed against the iron on the top. If any of your readers will try this, they will find no need to invest in an expensive apparatus.

I send you two untoned prints from negatives in daylight of two coins, a brass bureau handle, and a piece of notched ebonite with a few strands of white thread, you will notice a curious point that the white thread shews on the black ebonite.—I am, yours, &c., G. SCORAH.

DENSITY IN NEGATIVES.

To the EDITORS.

GENTLEMEN,—I am much obliged to Messrs. Hurter & Driffield for pointing out the error in the report of my lecture at the Camera Club. It should be the *ratio of densities*, not simply the *density*. There are other parts of the report that are so incomplete as to be practically erroneous, but those who are specially interested in the matter will, doubtless, refer to the report in the *Camera Club Journal*, which I shall hope to have an opportunity of revising.—I am, yours, &c.,
March 7, 1896, 11, *Eaton-rise, Ealing*. CHAPMAN JONES.

Answers to Correspondents.

*** *All matters intended for the text portion of this* JOURNAL, *including queries, must be addressed to* "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 2, *York-street, Covent Garden, London. Inattention to this ensures delay.*

*** *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

*** *Communications relating to Advertisements and general business affairs should be addressed to Messrs.* HENRY GREENWOOD & CO., 2, *York-street, Covent Garden, London.*

RECEIVED: W. W., F. PERCY, COLONEL, G ABBOTT, T. and H. JONES, ALFRED MASKELL, W. POUNCEY, and others. In our next.

COPYRIGHT.—L. H. E. As the copyright has not been registered, you can do nothing under the circumstances.

ACETYLENE APPARATUS.—A. C. (Clapham Junction). Messrs. F. S. Thorn & Co., of Camberwell, supply such apparatus.

REGISTRATION.—PHIL NEWMAN. As you have altered the picture, fresh registration is probably necessary—certainly it is advisable.

ELECTROS.—DORSET says: "Please give me, through the JOURNAL, address of a firm making a speciality of electros for catalogues."—Messrs. Sharrow & Anderson, Cambridge Circus, W.C., supply electros.

REPRODUCTIONS OF PAINTINGS.—W. B. B. Better ascertain if the copyright in the pictures has expired before you start issuing the prints. We see no objection to the exhibition of the picture you refer to, but tastes differ.

PARTNERSHIP.—JUSTICE. As the arrangement was only a verbal one, there is no legal agreement one way or the other. As you have the negatives, we presume you can make what use you like of them. Of course you have no copyright in them.

BROMIDE ENLARGEMENTS.—J. says: "Is there any way of strengthening weak bromide enlargements, such as are got from very thin negatives?"—Try a process of intensification as in the case of negatives: mercury, sulphite of soda, for example.

STUDIO.—S. & CO. From the description, which is by no means clear, in your letter, we should not like to give an opinion. If you will send us a rough sketch of the building as it stands, marking the aspect, we shall be pleased to advise as to the proposed alterations.

BACKING PRINTS.—LENS. Directions for use are usually supplied with the paper. However, it is simply stuck on the back of the wet print, and allowed to dry while on the glass. The prints can then be mounted in the ordinary manner, and the gloss will be retained.

PHOTO MECHANICAL VIEWS.—R. VEEVERS says: "Could you inform me where I can get a quantity of photographic views done by the photographic mechanical printing process?"—Our correspondent had better communicate with Messrs. Morgan & Kidd, Richmond, S.W.

SMOKING STOVE.—A smoky stove in the studio is, as you say, a great nuisance, but a remedy is not so easily suggested. Possibly, if there were less direct angles in the pipe, it would cure the evil; a greater length of pipe outside is sometimes a remedy, so also is a cowl on the top.

BICHROMATE.—H. C. H. From the description we should say that bichromate of potash has had nothing to do with the pimples about the body, as the hands are free. It is the hands, or parts coming in direct contact with the solution, that are first affected. So little as you use the salt, there is no likelihood of danger.

LENS FOR HAND CAMERA.—A. R. FODEN. For general hand-camera work a lens of five-and-a-half inches focus will be found the best. A good rectilinear of this focus will cover the quarter-plate well with a pretty large aperture. If the full opening is *f*-6, it will require a stop to give good definition all over the plate.

THE COPYRIGHT UNION.—COUNTRY PHOTO. It has been pointed out, time after time, that its members are at full liberty to charge as much as they like for the use of their copyright works—the only restriction is that they do not charge *less* than half-a-guinea. We certainly think it would be to your advantage to join the Union.

GOLD IN TONING.—T. WILLIS. If you get a fifteen-grain tube of chloride o gold to tone a full sheet of paper to a deep rich purple colour, you should be satisfied. If the paper is lightly salted and sensitised, and brown tones only are wanted, then a tube may suffice for a sheet and a half or a couple of sheets. The deeper the tones the larger is the quantity of gold required to produce them.

STUDIO.—R. W. G. The design numbered 3 will be decidedly the best for general all-round work. No. 1 would be preferable if the studio was to be used exclusively for copying or reproduction work. Have thick dark blue blinds (or green) on the south side, both top and side, and brown holland or light blue on the north side. Make both ends of the room opaque, as direct front light will never be required, and, if admitted, would give trouble.

BROMIDE ENLARGEMENTS.—BLISS asks: "Where can I obtain instructions for making and arranging an enlarging apparatus for bromide paper, &c., using my own lantern, condenser, and limelight; title and publisher of book on finishing bromide enlargements in black and white, also in water colour?"—In reply: There is a little book by S. H. Fry, published by Fallowfield (price, we think, 1s.), which will probably give the desired information.

CONVEYANCE OF GAS CYLINDERS.—INCONVENIENCE. The Royal Photographic Society, or the affiliated societies, can do nothing in the matter, and we do not see that they could do any good by agitating the question. The railway companies make their own by-laws and by them all using their lines must abide. Possibly, when the long-expected report to the Home Office is issued, they may be induced to relax some of the present restrictions, but it is very doubtful if they will.

DEMENY'S HAND CAMERA.—DR. GRANT writes: "On referring back to your JOURNAL of February 7, I find you speak of having described Demeny's hand camera in a previous number. Through pressure of time, I must have missed seeing it. Would you kindly give the numbers of the JOURNAL referring to it? Also would you kindly inform me as to the maker and price, &c., of Demeny's hand camera?"—We must refer our correspondent to the *Photo-Gazette* (Paris), from which the article we translated was taken.

FADED PRINTS.—G. HIGGINS says: "Will you kindly tell me if there is any means of restoring so that they may be copied: (1) Old faded albumenised prints; (2) An albumenised print that has turned a dirty yellow; (3) The cause of the last-named turning colour?"—1. If the print has actually faded, there is no means of restoring the details. 2. An immersion of the print in a weak solution of bichloride of mercury will generally remove the yellowness, and thus enable a better copy to be obtained. 3. Generally faulty manipulation.

SUBDUING LIGHT.—SOL. Instead of painting over the glass with white paint, to stop out the sun during the summer months, we should recommend the roof to be stippled over with starch paste to which has been added some whiting. This will obscure the glass, and is easily removed at the end of the sunny season. Oil paint is liable to turn yellow, and thus stop out more light than is, often, desirable; and, moreover, it is difficult of removal. Thin muslin, strained on light wooden frames, is excellent for intercepting the direct rays of the sun.

INTENSIFICATION.—FAL says: "In your issue of September 29, 1893, there is an article on *Rapid Intensification* with metol and sulphite of soda. This sometimes gives me excellent negatives, but occasionally it turns the film an amber colour in places, particularly at the edges, which is fatal to good printing. Would you kindly say in your next what is the reason of this?"—We cannot say definitely, but should assume either (1) that the hypo was not entirely removed from those portions of the film, or (2) that the washing after bleaching with mercury was insufficient.

FUSIBLE METAL.—C. WALKER. The most fusible metal is an alloy known as "fusible metal." There are several formulæ for it, and each gives different melting points. Some will melt if immersed in boiling water. Tin-lead and bismuth-lead and bismuth, in different proportions, are its constituents. By varying the proportions, different melting points are obtained. The addition of a little mercury will lower the temperature at which it melts. It may be made to melt as low even as about 150° Fahr. It will be better to purchase the alloy than to make it yourself. It may be had from any operative chemist's. It takes very sharp impressions.

DEFECTIVE LIGHT.—T. PAGE. As you cannot suit yourself with spectacles, although you have tried many shops, we suspect you are suffering from astigmatism, in which case you should consult a specialist. If your means are, as we take it from your letter they are, limited, go to one or other of the ophthalmic hospitals and have the eyes examined, and a formula for glasses will be given.

STRETCHED FILM.—T. BRAINE writes: "I enclose print, unburnished, and should feel obliged if you could give me the cause of the streaks that appear on the surface after mounting. It was damped before the starch mountant was applied in the usual way, and nothing whatever was visible till after the print was dry. Will you kindly inform me whether it is contraction of the paper, as I was very careful not to smear it in any way with my fingers? I may say that the print was thoroughly wetted, and also blotted off afterwards. I have about two dozen, and they are all more or less same as the one sent."—The cause of the marking is that the print has been strained in the mounting to such an extent that the film has strained from the paper.

COLLODIO-BROMIDE, WET COLLODION.—HAMLET says: "1. I am anxious to work the collodio-bromide process (wet) for stereoscopic transparencies, but have not time to make my own collodion. Is Mr. Brooks', Reigate, suitable? I see his name mentioned in this week's JOURNAL (Answers to Correspondents). 2. I have some recollection of a leading article on wet collodion in one of the ALMANACS, but cannot at the moment put my hand on it, perhaps you will please say. 3. Am I informed right that the silver bath must be kept in a strong light when not in use?"—In reply: 1. Brooks' collodion emulsion is suitable. 2. In the ALMANAC for 1896. 3. No; sunning the bath used to be resorted to when organic matter was present. This is probably to what you refer.

TELE-PHOTO LENSES, HAND CAMERAS.—C. THOMPSON says: "I am wishing to buy a lens for long-distant views (half-plate), mountains, &c., also wide-angle lens, and have been told that I can get a combination of the two—single lens distant and double wide-angle. Would you kindly tell me if this is the case; and, if so, what name it goes under; also, if the advertised cameras (without box cover), to be used as ordinary tripod cameras or hand cameras, are as satisfactory as separate ones for hand work?"—In reply: The questions are not quite clear. 1. We presume reference is made to the "tele-photographic lens," which fulfils the conditions mentioned. 2. There are several cameras which are adapted for use both as stand and hand cameras. A copy of our 1896 ALMANAC will give you much information on this point.

PHOTOGRAPHY FOR LADIES.—H. COHN says: "What do you think would be the best department for a lady printer to learn? I am twenty-two years of age, and have been printer for many years, but would like to take something else also. I think, if retouching is not really bad for the eyes, I would like it. What are the abilities necessary for a good retoucher? Would you kindly tell me if it is bad for the eyes, and in what way it affects them; also if any other branch would be better? I would like something that I could go abroad with by advertising, perhaps after a few years."—In reply: A knowledge of retouching is not very difficult to acquire from a competent teacher, and does not, as a rule, injure the eyes. If, in addition to printing and retouching, our correspondent would also learn operating, it would be all the better for her chances of success, either at home or abroad.

SPOTTY PRINTS.—ZERO asks: "Could you kindly inform me what you think would be the cause of the spots on the enclosed prints, and how best to avoid them in the future? They have gone so after only being less than two months in the show-case. I have never met with this difficulty before, and am rather at a loss how to set about to find a remedy, as I cannot think what would be the cause of it. I have had specimens in the show-cases over six months without ever showing any traces of any defects, but this time I have had to take them out after being exposed for about six weeks, as they have all gone similar to the enclosed samples. I have no doubt but what your wide experience will soon point out wherein the defect lies on seeing the enclosed two prints. If it had been a case of fading, I would have put the matter down as a case of not being properly fixed, but these spots I don't think could be exactly called fading. Do you think the mounts could have anything to do with it?"—The spots may be due to the manipulation, the mountant, or the mounts. The most probable cause, however, is bronze powder on the mounts, as the lettering is printed in bronze.

FAILURE IN REDUCING.—RESIDUE writes: "Thank you for your kind information in Correspondence column in answer to my inquiries. I venture to ask you a further question, and I enclose you a small piece of the result of my smelting, thinking, perhaps, you could tell me what it is; it did not melt out into metallic silver, but all formed at the bottom of the crucible in a thick mass, like the piece I send you. It is the chloride, formed with adding salt to an old sensitising bath; this I filtered off, and, when dry, added one part and a half, as you kindly informed me, of the mixed carbonates of soda and potash. I tried it twice on the fire, two lots, and got the same result, so that, if you will kindly answer once more the following questions, I should be greatly obliged:—1. What can I do with this, that I have tried to melt, for it is nearly a pound in weight, like sample I send you? 2. Is it oxide of silver? 3. Can you assign any reason for the flux not running fine and the silver melting out? Thanking you for your past kindness."—1. and 3. The cause of failure is that the residue has not been subjected to nearly sufficient heat to reduce the silver to the metallic state. Put the residue back in the fire and keep it boiling at nearly a white heat for twenty minutes or half an hour, or until the contents of the crucible cease to boil. 2. No. You speak of putting the crucible "on the fire;" if you are trying to reduce the residue in an ordinary fire, you will certainly fail. The work must be done in a proper furnace, or sufficient heat will not be obtained.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 1872. Vol. XLIII.—MARCH 20, 1896.

Contents.

EX CATHEDRÂ.

With reference to our suggestion of last week that professional photographers might profitably make a speciality of the "new" photography, a friend draws our attention to the fact that Mr. Friese Greene, some weeks ago, advertised that he was prepared to exhibit the process in action. His charge for admission was 2*s.* 6*d.*, while for 5*s.* the visitor might have his hand or foot photographed.

* * *

Mr. G. Ridsdale Cleare, photographer, of 97, Lower Clapton-road, N.E., also writes to us as follows on the same subject: "Referring to your first editorial paragraph in last week's Journal, I beg to inform you that I am making the necessary preparations for the production of shadowgraphs by the Röntgen rays, and hope, within a week, to be prepared to execute orders from hospitals, surgeons, and the public generally."

* * *

Mr. A. A. C. Swinton, whose letter will be found in our correspondence columns, also states that he has decided to establish a laboratory specially devoted to the "new" photography.

* * *

Still another letter on the same subject has reached us; this is from Mr. W. E. Gray, F.R.P.S., photographer, of 92, Queen's-road, Bayswater. Mr. Gray observes: "Referring to the first paragraph in the last number of the Journal, I enclose you a contact bromide print from one of my negatives. I have been working at Röntgen 'photography' a great deal with some medical friends, and am quite prepared to undertake the work commercially. In fact, I have already arranged about the advertisements in the medical journals." Besides the above-mentioned communications on the subject, we have had visits from some professional photographers, who have been struck by our suggestion, but yet appear doubtful whether sufficient scope really exists for the new branch of work opened up by Röntgen's experiments. Possibly they will derive encouragement from the examples set them by Mr. Friese Greene, Mr. Cleare, Mr. Swinton, and Mr. Gray. The old adage of "nothing venture, nothing gain," here applies with peculiar force. The gain, of course, is not likely to be very great; on the other hand, the necessary outlay is relatively not large.

* * *

Our professional and amateur readers, and the trade generally, will, we are sure, thank us for giving them the address of a gentleman who is prepared, "with something akin to certainty," to supply fine weather whenever it is required. This gentleman, whose name is J. Collinson, dates from Sandown, Isle of Wight, and his circular, of which we append a copy, has, we believe, been addressed to fruit and vegetable-growers. We presume he would have no objection to also catering for the wants of photographers.

* * *

Mr. Collinson says: "In making business arrangements, the mind frequently suggests that, could a certain kind of weather be depended upon for a few days, or for a week or two, say, rain or sunshine, frost or mildness, or cold, stocks of merchandise, provisions, fuel, &c., could be dealt with with more confidence than under the present conditions. By the discovery of means for regulating a force termed Odylic force, I can, with something akin to certainty, arrange for current weather to be such as you might consider best for the re-

quirements of your business. If, therefore, you, or any of the other leading firms in your kind of business, would, singly or in combination, arrange with me, I would, from time to time, effect such changes in the weather, by means of Odylic force, as might be considered most desirable or necessary."

* * *

A MAN with such wonderful command over the elements as Mr. Collinson claims to enjoy should not be lost sight of by the photographic fraternity. The obvious plan to be adopted is for the photographers of particular towns and districts to club together, and get Mr. Collinson's best terms for fine weather as they may require it. Possibly, Mr. Collinson could also be induced to supply Odylic force in tanks or barrels, so that photographers could make their own fine weather whenever they felt so disposed.

* * *

MR. DAVIS, who opened a discussion on "Art and Photography," at the last meeting of the Richmond Camera Club, is no friend to the claims of photography being ranked as an art. He maintained that the claim of photography to be considered as art in the same sense as sculpture and painting are so regarded was quite inadmissible, chiefly on account of the mechanical nature of the means employed, the narrowness of its scope, and *the absence of all demand on the creative and imaginative faculties of those who use it*. He considered that the art treasury of the world was no whit the richer for the masterpieces of photography, and that, should no more photographic exhibitions be held in the future, the world of art would be insensible of their loss. These views run counter to those held by many photographers and some artists, and are noticeable for their refreshing boldness and unconventionality. At the same time, we consider, in respect of the passage we have italicised, that Mr. Davis somewhat spoils his case by overstating it.

THE USE OF THE SWING BACK IN ENLARGING.

DURING last autumn we published an article under the above heading, pointing out the possible utility of the swing back in correcting faulty perpendiculars when enlarging from small negatives, and we should not now refer to the matter again but for the fact that M. Victor Selb has since taxed us with plagiarising an article or articles of his on a similar subject in a foreign journal, and has also, still more recently (*ante*, page 125) denied the possibility of so applying the swing back. We can only repeat what we have already said regarding that gentleman's articles, that we had no knowledge of them at the time we wrote, nor have we even, up to the present time, seen them; but, from M. Selb's denial, it would seem that he and we have written on entirely different subjects.

In a letter, with diagrams, which we need not here reproduce, M. Selb says, on February 21: "When negative and positive to be reproduced are of equal sizes and swing from the perpendicular a same number of degrees, the rays are of equal length—A B as long as C D. When a small negative is placed in a similar position to produce an enlargement, say, of four diameters, the rays or lines are unequally long—E F is much shorter than G H. *The consequence is, the enlarged image is vastly out of focus.*" The italics are ours, and this statement seems to show that the writer has not only failed to grasp the gist of the subject on which we wrote, but is also ignorant of the first rules of conjugate foci. It is precisely on account of this difference in the length of the "rays or lines" to which he refers that sharpness in the enlargement is due.

We may commence by pointing out that M. Selb is incorrect in assuming that, when the negative and reproduction are of equal sizes, they are necessarily swung from the perpendicular the same number of degrees. It is possible that, under some conditions, such a state of affairs might exist, but in actual practice we doubt it, and at least there exists no ready means such as we gave for calculating the position of the negative in order to secure at once perpendicularity and sharpness; but, if M. Selb will refer once more to our original article, he will see why, even in copying by the same dimensions, the "rays and lines" he refers to must necessarily be of unequal length, and the negative and positive respectively swung at a slightly different angle.

Precisely the same rules govern the production of an enlargement, and the same proportionate difference exists between the length of the line that crosses from the top of the negative to the bottom of the reproduction and that which crosses from the bottom of the former to the top of the latter; but, of course, in the case of an enlargement, owing to the greater focal distance, the actual difference will be greater, and it is precisely that difference on which we depend for obtaining the sharpness which we claim and M. Selb denies. The diagrams which accompany his letter show the amount of swing in an absurdly exaggerated degree; but, if he will take the trouble to plot out on a sheet of paper the actual positions of a four-inch negative and an enlargement up to five diameters, using a six-inch focus lens, he will find that the difference between the lines connecting their opposite extremities does not exceed one inch in a total of nearly four feet when the amount of distortion to be corrected is more than will be found in an average negative. That degree of alteration in the longer conjugate in an enlargement of those dimensions would not make a "vast" difference in the quality of the definition, even if it were made in the wrong direction; but, when by the simplest optical laws it is necessary in order to get perfect definition, the absurdity of M. Selb's contention is obvious.

Let us briefly recapitulate the position we take. A negative in which the perpendiculars are faulty is to be reproduced—whether to the same or different dimensions matters not in the least—and, in order to correct those faulty lines, one extremity of the negative must be slightly enlarged or widened, while the other is copied same size. The enlargement is effected by inclining either the negative, the sensitive surface, or both, at such an angle, or angles, that a greater distance exists between the foreground of the negative and the top of the buildings whose perpendiculars fall in in the reproduction; in fact, the very "redressment" of the lines depends upon this difference, which M. Selb objects to. So far as the mere correction of the lines is concerned, it can be secured, as we have said, by sloping the negative or the sensitive surface simply; but there is only one correct position for each if absolute sharpness is to be combined with correct perpendiculars, and in our original article we showed how those positions might be arrived at by calculation in a very simple manner.

Now, when the swing back is employed in taking the negative, it is used in defiance of all the requirements of *definition*, and with the simple object of securing correct perpendiculars; and, so far as sharpness is concerned, the best compromise possible is made between the different portions of the plate by

using a small stop; but, if we adopt the reverse method of securing in the negative the greatest possible sharpness the lens will give without regard to the perpendicularity of the lines, those can be corrected in the process of reproduction without in the least injuring the definition of the original negative. When the definition of the latter, owing to the use of the swing back, leaves room for improvement, it is certainly not in the process of enlargement that that improvement will be effected.

Some misconception exists in many quarters as to the extent of the distortion produced by tilting the camera. It is difficult to produce more than two or three degrees' departure from the perpendicular by tilting the tripod to the utmost limit of safety in the matter of stability, though the error will vary with the distance of the object and the focus of the lens. The angle at which the back must be swung to correct this is much greater, but whatever the error may be when the swing is not used is well within the power of correction in course of reproduction.

Röntgen Rays.—There is no waning in the popularity of this subject, and, owing to the comparative ease with which the effects are attainable, and with apparatus of an almost elementary description, there is a complete surfeit of accounts of mere useless reproductions of Röntgen's experiments from every direction. Amongst scientific men a problem of paramount interest is opened out by the discovery of the X rays, namely, the possibility of their being, and being proved to be, longitudinal vibrations, a condition of the ether which, as a writer in one of the reviews states, is looked upon as the last resource of the physicist to explain unexplainable phenomena in the same manner as the physician diagnoses "nerves" as the cause of obscure diseases. At the same time, the number of believers in these vibrations is steadily increasing, and quite recently Lord Kelvin suggested some experiments for determining the existence of such rays. Lord Blytheswood obtained, and exhibited, sharp photographic effects on a dry plate placed in a dark slide, and the whole wrapped in several folds of black velvet, and then placed in front of the space between the main electrodes of a powerful Wimshurst machine, but not in the direct line of the discharge. He also obtained results of the same character when the slide was held in the direct line of the discharge. Lord Kelvin believes that the effects were wholly or mainly due to sparking from the brass hinges of the shutter, and suggests the use of a closed aluminium box, and no velvet instead of the slide. There would then be no sparking, and, if a satisfactory photograph were produced, the truth of Röntgen's longitudinal wave explanation would be proved, though the absence of such effect would not necessarily disprove it.

Reflection of the Rays.—Professor G. Vicentini and Dr. G. Packer found distinct evidences of an irregular reflection in an experiment they carried out with a brass parabolic mirror. The Crookes' tube and the sensitive plate were placed on opposite sides of an iron plate, so that the rays, if they were to reach the sensitive surface, had to be reflected from the mirror. These observers exhibited their results before the Scientific Institute of Venice. They found that a glass mirror arranged in a manner similar to that of brass gave no reflection whatever.

The Best Form of Tube.—Many new forms of tube are being made, the main object being to devise a construction such as shall cause the rays to emanate as nearly from a point as possible, for it is evident that, unless the opaque object almost touch the glass, there will be penumbra where the radiations emanate from an area of measurable magnitude. Professor John McKay, of the Packer Institute, Brooklyn, has described what he considers the most suitable shape. It is five inches long, and a little over an inch in diameter, a kind sold as a "perfect vacuum" tube; the electrodes are of copper, and only an eighth of an inch apart; but the vacuum is so good that the current will preferably pass round the tube rather than cross the small space. It produces very little light, and does not get heated. The rays radiate in all directions from the centre, so that simultaneous exposures may be made in all directions from the centre.

A Röntgen Kinetoscope.—Mr. E. P. Thompson exhibits visible effects by means of a fluorescent screen, showing the action of bones in motion, such as those of the hand, and he hopes to show the skeleton of the bones of a bird in flight. He makes his screen of the barium platino-cyanide by dusting it over an adhesive surface of varnish coated upon tracing cloth.

A Crookes' Tube not Necessary.—It has already been shown that the Röntgen effects may be obtained without a Crookes tube. Professor McKay obtains the effects from a coil actuated by the discharge from a Leyden jar. Mr. M. F. O'Reilly suggests, in last week's *Nature*, that the attempt should be made to produce sciographs by means of the emanations from the auroral light.

Pinhole Photographs of the Ray Apparatus.—Mr. Ralph W. Lawrence writes to *Nature* from the Massachusetts Institute of Technology that, by means of a "pinhole" in a sheet of lead, the hole being blocked by aluminium, he has obtained an image of the apparatus and rays. The pictures produced "show very distinctly the two electrodes, while the glass tube, which appears very brightly illuminated to the eye, is scarcely perceptible. It would appear from this that nearly, if not all, the so-called X rays proceed directly from the electrodes of the tube, and not from the glass where this is acted on by the cathode rays."

More Honours for Röntgen.—The learned Professor is to be congratulated on the honours being showered upon him from all quarters, and in so short a time after the publication of his process. The first royal honour was from the Emperor of Germany, and the most recent one from the Prince Regent of Bavaria, who has just sent him a patent of nobility. Evidently meritorious work and discovery is more quickly recognised and suitably acknowledged by royalty in Germany than is the case in England. We doubt much, if the Röntgen method had been worked out by an Englishman, he would have had the honours so quickly conferred upon him by English royalty that Röntgen has in Germany.

By the way, the Röntgen "photography" has already found its way into the Law Courts as evidence. At the recent Nottingham Assizes, in an action for damages for injury through a faulty staircase, photographs of the feet of plaintiff — an actress — taken by Professor Ramsey, at University College, by the Röntgen rays, were shown to prove the injury sustained. Whether the photographs had any influence with the jury or not it is impossible to say, but in the end they awarded the plaintiff substantial damages. During the hearing of the case some amusing remarks were made. On the defendant's counsel telling one of the witnesses that he ought to have scientific evidence as to the value of the rays, Mr. Justice Hawkins remarked, "You might send a man to the lunatic asylum, you know, by photographing his head." One of the barristers, looking at the photographs, asked, "Is this the Trilby?" &c. Evidently the "new photography" was treated with a certain degree of levity, on its first appearance as a witness, by gentlemen of the long robe.

Surgical Use of the X Rays.—The employment of the Röntgen radiations in surgery continues to meet with many applications, and this method of diagnosis will, no doubt, take a permanent place in our hospitals, if not in private practice as well; but it will be well if surgeons at once appreciate the fact that their new ally may possibly become a tacit witness against them as well as a valuable helper. An instance of such an unfortunate *contretemps* lately came under our notice. A gentleman, well known in photographic circles, had the misfortune, when a youth, to break

his forearm, and break it badly too. The limb was duly set by a surgeon, and the accident became a thing of the past, save that the arm never regained its normal strength, and exhibited a deformed appearance. It recently occurred to this maimed one to see, by means of the Röntgen rays, what kind of a skeleton this limb of his presented, and why it was that the arm was so deformed. So he hied him to a friend who owned an induction coil and a Crookes' tube, and, placing his arm on a boxed plate, had a shadow photograph of it taken. When that plate was developed, it exhibited in a graphic manner the very faulty way in which the broken bone had been set. The *ulna*, instead of being in close partnership with its fellow bone, the *radius*, was entirely thrust out of place, and its head appeared like an excrescence at the side of the wrist, instead of being part of the arm. "It's a good thing for him," said the victim, "that the surgeon who set my arm is dead, otherwise I would certainly take action against him." Let surgeons, therefore, be careful in recommending to their patients the use of a Crookes' tube, in case the revelations it affords should recoil upon their own heads.

Hampstead Heath.—The other day we were commenting upon the appeal which artists have recently made to the London County Council to stay their official hands in the conversion of various parts of London's most beautiful open space to the condition of a park. This protest will, doubtless, have its effect, for there must be men on the Council who can appreciate this desire to preserve the Heath in its natural state. It should, however, be remembered that the Council may fairly be credited with many improvements on the Heath. The ugly brickfields have been hidden under a mass of verdure, and the trees have for the most part been left undisturbed. The beautiful clump of pines which crowned the reputed grave of Boadicea have withered one after the other, and the recent abortive search for relics of the Queen of the Icenæ seems to have given them the *coup de grace*. Surely fresh trees of the same species might be planted here, for the Scotch fir or mountain pine flourishes well on this sandy soil. Witness that other clump of pines near "The Spaniards." It is not perhaps generally known that these trees form part of an avenue which stretched from "The Spaniards" to North End, a distance of about five hundred yards. They were planted by one Turner—not the artist, but a worthy tobacconist of Fleet-street, who lived here, and evidently had an eye for the picturesque in nature. Posterity owes him much for this beautiful addition to one of the beauty spots of Middlesex.

Sunday Opening of the Museums and Art Galleries.—Each year that the Guildhall Loan Exhibition of Pictures has been open to the public on Sunday afternoons, we have commented on the good attendances, and the fact that the opening was a boon to those who could not see the pictures on other days. Last week the House of Commons decided, by a large majority, on Mr. Massey-Mainwaring's motion, that all the museums and art galleries are to be open on Sunday afternoons. How far this has been brought about by the action of the City in opening the loan collection on Sundays, and the success in every way that attended it is, of course, impossible to say, but there is no question it had great weight. Many times similar motions have been brought before the House, but have always been rejected by large majorities. There is little doubt that many photographers, who are fully occupied on week days, will now avail themselves of the opportunity of studying the works shown in our art galleries, and it is to be hoped with profit as well as enjoyment.

Speaking of art galleries reminds us that the annual report of the Director of the National Gallery was issued last Friday. It shows that our national collection has been considerably enriched by the addition of a large number of fresh works, which have been acquired by purchases, bequests, and by presentations. The statistics show that the Gallery was visited, on the 210 days it was open to the public gratuitously, by little short of half a million persons, the daily average being 2250. On students' days (Thursdays and Fridays), when sixpence admission is charged, 41,515 were admitted. The total number of students' attendances for the year 1895 was over 20,000. It will be interesting to see, in the next annual report, what the Sunday attendances will have been.

The Recent Fatal Cylinder Explosion.—The inquest on the unfortunate chemist who was killed at the laboratory of Messrs. Redwood and Hailes, Red Lion-square, by the bursting of a gas cylinder, was concluded one day last week. Although some of the lay press, at the time of the accident, described it as the bursting of a compressed oxygen cylinder, the evidence at the inquiry showed that the cylinder was not charged with compressed oxygen at all, but with stearic acid, glucose, and alcohol, together with a little acetic acid and a few iron nails. The vessel was being heated over a furnace when it exploded. It was stated that there was a valve to the cylinder, but it was closed. The evidence of the experts from the Home Office is reassuring as to the safety of cylinders, for it was mentioned that this one was a good one of its kind, and there was not the slightest fault in it; also that the accident was due to the mistake of filling the cylinder quite full, and then overheating it. A very noteworthy circumstance in connexion with this cylinder, as with the one that burst at Fenchurch-street, is that it was rent from top to bottom, and did not fly into pieces to scatter destruction around like a bomb shell—with which we have heard them compared—would do.

At the inquest a photograph of the room and its contents, taken immediately after the accident, and before anything had been disturbed, was shown. If this could be done in all cases of fatal accidents, it would be far more valuable evidence to the coroner and jury than much of the verbal evidence given by witnesses. Unfortunately, however, a camera is not always readily available, as seems to have been the case in this instance.

FOREIGN NEWS AND NOTES.

A Turmeric Printing Process.—A writer in the *Photographische Chronik* describes this as follows:—Turmeric is derived from the rhizome of two varieties of plants, *Curcuma longa* and *Curcuma rotunda;* the best kind is the Chinese, the next the Japanese, the worst the Barbadoes. Turmeric may be obtained in the form of powder, and gives up to alcohol its peculiar orange colouring matter, a solution of which on paper or metal gives a negative from a negative as the colour is discharged by light, and only by development with spirit and water, or, with long exposure, by the former alone gives positives.

It can be used for zincography, photo-lithography, and three-colour printing. For zincography it is used as follows: 10 parts of Chinese turmeric should be dissolved in 100 parts of alcohol. If chloroform is used instead of alcohol, more soluble matter is extracted, and with the addition of 5 parts of oil of lavender it withstands acid better, and the solution is more sensitive. In order to judge better of development, 2 parts of a saturated alcoholic solution of methyl-violet should be added. The image thus obtained is quite as resistant as asphalt, if not developed. The development is effected with alcohol. Although this process can be used for zinc etching, it presents no advantages over the albumen or fish-glue processes.

For photogravure it possesses the following advantages:—It does away entirely with the costly carbon paper and its concomitant disadvantages of slow drying after sensitising and slow development, the formation of blisters, and the difficulty of seeing the image in the etching bath.

It must not be assumed that there is any difficulty in coating the turmeric solution, or that the asphalt will dissolve. The asphalt grain is rendered insoluble by the heating and by exposure to light.

For photo-lithography, ordinary litho paper is coated with the above-mentioned turmeric and lavender solution, dried and exposed.

Then the paper is squeegeed to a zinc plate moistened with spirit, or to a stone moistened with water; these are then warmed from below till the resin has melted, and then the paper removed by damping, and the zinc or stone moderately etched. For zinc, the etching solution is composed of

Water	1000 parts.
Gum solution (1 : 5)	100 „
Nitric acid	15 „

for a stone, of

Water	100 parts.
Gum solution	40 „
Acetic acid	10 „

The stone, when long runs are required, is inked up, and again etched. The advantages of this process are that it does away with the inking up of the print, the wearisome washing of the print, the delicate development of the print, and the difficult transfer.

For three-colour printing the following may be used as a filter for the blue negative:—

Chloroform	100 parts.
Turmeric	15 „
Dragon's blood	1 part.

The solution is allowed to stand for twenty-four hours, and then filtered.

This process may be also be used for printing from negatives in the ordinary way, and by substituting other light-sensitive resins, such as asphalt, guaiacum, dragon's blood, and so on, various shades may be obtained.

Black Varnish.—Herr Fleck strongly recommends the following as possessing several advantages over the ordinary formula:—

Sandarac	10 parts.
Absolute alcohol	100 „
Nigrosin (five per cent. alcohol solution)	10 „

A Rival to Herkomer's "Artist-engraving" Process.—It is reported that a Swiss named Zürcher has discovered a process which gives far more successful results than Professor Herkomer's new (?) process, and that he has sold it to three Amsterdam firms.

Dead Black Varnish.—The following formula is suggested as giving an absolutely dead, lustreless surface:—

Water	500 parts.
Borax	15 „
Shellac	30 „
Glycerine	15 „

Dissolve and add—

Aniline black	60 parts,

and apply with a brush.

Reducing Fog.—Chemical fog, according to the *Photographische Archiv*, may be eliminated by immersing the fixed and well-washed negative in:—

Sulphate of copper	5 parts,
Potassium bromide	5 „
Water	500 „

for about half to one minute, or until the surface is just bleached, then refixing. The negative, after this treatment, can, if necessary, be intensified.

Ferric Sulphate as Restrainer. — Le Roy, in the *Bulletin de la Société Française*, suggests the use of ferric sulphate as a restrainer in the ferrous-oxalate developer, and states that it is better than using an old developer, as its action is more certain. About ten or twenty drops of a ten per cent. solution should be added to each ounce of the developer. Ferric sulphate, or persulphate of iron, as it is usually called, is quoted at 2*s.* 6*d.* per pound.

Varnishing Films.—Balagny recommends giving cut films a coating of three per cent. amyl-acetate collodion, to which about two per cent. of castor oil has been added. The film should be fastened by pins to a board, and brushed over with the above varnish, a narrow margin being left untouched. When the varnish is dry, the film should be turned over and treated in exactly the same way. He states that films treated in this way will not curl.

To Blacken Steel and Iron.—In *Science Pratique* a mixture of

Mercuric chloride	2 parts,
Cupric chloride	1 part,
Hydrochloric acid	6 parts,
Alcohol	5 „
Water	50 „

is suggested for blacking steel. The article should be well cleaned and immersed in the above for a few minutes, allowed to dry and then placed in boiling water for half an hour, and the operation repeated if not black enough.

A Reducer for Chloride Prints.—Over-printed proofs on collodio or gelatino-chloride paper may be reduced by immersion in a bath of

Hypo	10 parts.
Sol. ammon. bichromate (one per cent.)	2 „
Water	100 „

THE PHOTOGRAPHIC NATURALIST.

III.—Geological Photography.

Introductory—The Camera in Topography—Photography of Rock Scenery—Photography and Vulcanology—Subterranean Photography—Museum Photography—Photography of Rock Sections—Conclusion.

Introductory.

In former papers* an attempt was made to summarise the various methods of utilising photography in the two chief departments of natural history, viz., botany and zoology: but there still remains to be described the application of photographic methods to the study of the inanimate world. The employment of photography, both in physiography and in geology, has, of late years, assumed a new interest, owing to the rapidly increasing use of the camera for the purpose of illustrating geological memoirs. It is true that the great perfection of modern photo-mechanical processes of block production is mainly responsible for the impetus which has been given to geological photography; but the result is, nevertheless, the same, the services of photography can no longer be dispensed with by the competent geologist, either in the field or in the laboratory. The timely recognition of this fact led the British Association, a few years ago, to appoint a committee for the purpose of securing to geology the full advantages of the spread of amateur photography amongst the numerous natural history societies scattered over the length and breadth of the country. The recommendations of this committee are easily accessible, and need not be recapitulated here. The result of their efforts has been to accumulate a large mass of photographs, many of them of exceptional interest and value, which might otherwise have been lost to the scientific world. These photographs, arranged in Zaehnsdorf's self-binding mounts, are destined to be placed in the library of the Museum of Practical Geology. They treat of almost every department of geology and physiography, of inland erosion by wind and water, sea-coast erosion, cavern formation, basaltic structures, glacial erosion, fossils *in situ*, and all forms of earth sculpture. But, although the invitation of the committee has met with a fair response, much yet remains to be done, and there is a good opening for photographers, both professional and amateur, to assist in making the series as complete as possible.

As examples of the great value of photographs for illustrating geological memoirs, we may refer, amongst many others, to the proceedings of the Geologists' Association, which are often most effectively illustrated by blocks from actual photographs, as well as to the beautifully illustrated reports of the United States Geological

* See The British Journal of Photography, vol. xlii.

Survey, and the valuable work of Savile Kent on *The Great Barrier Reef of Australia*, not to mention earlier productions, such as *The Monograph on Echini*, illustrated in 1872, by Professor Agassiz, by means of carbon prints, and Johnston-Lavis' book on the volcanoes of the Lipari Islands. The Museum of Science and Art, Dublin, displays a fine series of geological photographs, chiefly the work of amateurs, presented to the Geological Survey of Ireland.

We will now examine more closely some of the special applications of photography to geological investigation.

The Camera in Topography.

In every geological survey it is of the utmost importance that the topography of the district should be as accurately delineated as possible. To do this by the usual methods of triangulation involves an immense expenditure of time and energy, quite out of the question where large districts have to be rapidly surveyed. But in photography we have a means of securing this object, not only with great rapidity, but also with any required degree of accuracy, an inestimable advantage when working in a district which has not previously been mapped.

One of the novelties exhibited at the Chicago Exhibition was a photographic map of the Rocky Mountains Park of Canada. This map was made up of twelve sheets, each covering an area of about sixty-three square miles, and every measurement usually made upon the ground itself, was obtained from photographs by the application of the laws of lens perspective.* The photographs were made from seventeen stations to each sheet, each station being visible from at least two others.

This development of photography, pointed out more than thirty years ago by Chevallier and others, has attracted more attention in France and Germany than in this country. Although it has not, for various reasons, supplanted the older methods of mapping, yet for rapid surveys in open country it promises to be of immense advantage to the geologist.

Quite recently a camera has been specially designed for geological survey, by Mr. J. Bridges Lee.† A photographic camera is fitted with a magnetic needle, carrying a vertical transparent scale divided into 360 degrees. The lens carries two cross fibres intersecting at right angles. On accurately levelling the camera by levelling screws, any photograph taken by it has automatically recorded upon it the image of the fibres, showing the true bearing of the vertical plane through the centre of the lens, as well as the horizontal plane at right angles to it. The camera carries a telescopic finder with crossed fibres, and revolves on a graduated circle, by means of which it can be turned through any desired angle.

Camera surveying has also been recently adopted by Dr. Otto J. Klotz in mapping the Baird Glacier, Alaska.‡ Any camera can be adapted, with little trouble, for this purpose, if the surveyor is provided with a Galton's pocket altazimuth, or even an ordinary prismatic compass; but the complete discussion of all the details involved would occupy more space than can now be given to it.

One of the great difficulties of a photographic survey is the impossibility of recognising the same point in the different photographs from which the results are plotted. This makes it absolutely essential that the same person should both take the photograph and plot the work. It would materially increase the permanent value of geological photographs in general if, in all cases, the true compass bearing of the camera were registered at the time of taking the view.

Photography of Rock Scenery.

Geological photographs should show as far as possible the characteristic features of the various rocks and their influence upon scenery. The nature of the rock, for example, has an important influence upon the contour of mountain masses. The profile of a limestone mountain, possessing what Leslie Stephen calls the "writing desk formation," the ruined masonry appearance of dolomite, the sharp spikes of "aiguilles" and the massive flat-topped outline of a granite boss, these are examples of the points in a mountain photograph which appeal to the eye of the geologist.

Unfortunately, there is often some considerable difficulty in properly rendering distant views of mountainous country. A lens of short focus is useless for this purpose, and a twelve-inch lens is rarely at the command of the geologist, who must of necessity be as lightly equipped as possible. Donkin recommended the simple device of halving a symmetrical combination, with the result of doubling the focal length of the lens. The swing back also comes into prominence in mountain work. There is a tendency to tilt the camera upwards, and, if the back is not vertical under these circumstances, the effect will be to flatten the mountain to a marked degree. In the same way the slope is exaggerated by leaning the ground glass forward. Burton, in producing photographic illustrations for his work on *The Volcanoes of Japan*, was impressed with the importance of paying special attention to atmospheric effect. His advice is to resist the natural temptation to photograph mountains when the atmosphere is clearest, but to choose a time when there is a certain amount of haze. Otherwise no true idea of size or grandeur can be obtained, the photograph looking more like the picture of a model only. The idea of distance is also helped by the proper selection of a foreground.

Another difficulty in photographing distant mountains is the tendency for the outlines to merge into the sky, an evil which is often remedied by the use of the yellow screen and orthochromatic plates. Where there is much snow or glacial ice, it becomes still more difficult to preserve those good half-tones upon which the success of a picture depends. Mrs. Main recommends in this case the use of slow plates with a small stop and full exposure, taking care to take such photographs in sunshine rather than in dull weather. Glaciers especially reflect a bluish light, most difficult to deal with satisfactorily unless the yellow screen is used.

J. Vincent Elsden.

PHOTOGRAPHS IN "NATURAL COLOURS:" SELLE'S PROCESS.

The inventor of this process, Dr. Gustav Selle, of Brandenburg, thus describes his improvements in the production of "photographs in natural colours:"—

The present known processes for producing photographs in colours are, broadly, of two kinds. In Lippmann's process, the coloured image is produced on one plate only in interference colours, whilst, in the other method, the coloured photograph is produced by superposing three single coloured images, produced with artificial colours one upon the other.

In Lippmann's process the photography of living or moving objects seems practically excluded, on account of the necessarily long duration of exposure, whilst, in the process described in the present specification, which belongs to the second category on account of the relatively short duration of exposure, also objects which are quiet only for a short time can be photographed in colours. In this present method it is neither necessary to make for each copy of the photograph a new exposure, as in Lippman's method, nor is the production so difficult and circumstantial as, for example, in the Vogel-Ulrich method, in which must be produced coloured plates from which printed impressions are made.

The present process is divided essentially into two parts.

1. The production of the negative.
2. The production by copying of the positive.

The production of the negative is made in the known manner by photographing an object three times, one after the other—first, behind a red; secondly, behind a green; and, thirdly, behind a dark blue, light filter.

The positive is produced by making three positives behind the corresponding three negatives, each being then coloured in the colour complementary to the light filter of its corresponding negative, and by putting these three positives one over the other.

Such a complementary positive is made by covering with a thin collodion skin, serving as image carrier, a glass plate, which is surrounded with a rim of gelatine solution, and then pouring over the same plate a chrom-gelatine emulsion.

After having dried the plate so prepared, it is exposed behind one of the three negatives, for example, the negative I. for red, then washed in cold water, and put into a colour solution complementary to red, for example, in a colour bath of methyl blue.

The plate remains in this bath until the blue image is completely developed, whereupon it is taken out, dried, and covered with collodion.

In the same manner a second positive is produced by exposing a second glass plate prepared in the same manner behind the negative II., taken with the green light filter. This is now developed in a colour bath complementary to green, for example, in one of fuchsin, and finally treated exactly as the blue one.

In the same way is produced behind negative III. the positive III., which is developed in a colour bath complementary to blue, for example, in one of helianthin.

When all three positives are produced, they are superposed as follows:—

The edges of the rose image II. are cut, and a transfer paper is squeezed upon it; the thin collodion skin is taken off with the paper, and transferred upon positive I. (blue), which has been previously covered with gelatine as adhesive substance, the two images are put one upon the other, pressed together, and transfer paper is taken off. In the same way the positive III. (yellow) is transferred on the upper of the other two.

and a positive in natural colours is thus produced, which consists of collodion or other thin skins, and can be easily transferred to a permanent support of paper, opal, glass, &c.

The inventor's claims are for: 1. A positive process for producing coloured photographs, comprising the employment of very thin but transportable collodion skins as image-carriers, which are treated with chrom-gelatine emulsion, whereupon, after exposure behind corresponding negatives, the soluble salts are washed out in cold water, and the image made sensitive in this manner for colour baths is developed in corresponding colour baths. 2. In the method described in Claim 1, the production of photographs in natural colours in the known three-colours system, by putting single coloured collodion skins produced according to Claim 1 one upon the other.

PHOTOGRAPHS IN COLOURS: LUMIÈRE'S PROCESS.

Messrs. A. & L. Lumière, of Lyons, have patented "an improved photographic process giving, without transfer, images with their half-tints, and the application of this process to photography in colours."

The process is thus described:—As is well known, Messrs. Cros and Ducos du Hauron's method of photographically obtaining colours consists in producing three negatives of the same object, each negative representing the negative image of the red, yellow, and blue radiations emitted or reflected by the said object, each of these negatives being then used for obtaining a monochrome image in either red, yellow, or blue. The superposition of these three monochromes reconstitutes, therefore, the colours of the original.

This process has not hitherto been practically adopted, as the obtaining and superposition of monochromes have presented great difficulties.

This result has, nevertheless, been accomplished by the communicators by the employment of the following photographic process using bichromated mucilages.

They have remarked that bichromated glue, soluble in a cold state, which does not give the demi-tints when it is employed alone, acquires this property when insoluble substances are added to it under certain conditions. If, for example, to a ten per cent. solution of glue there is added about five per cent. of bichromate of ammonia, and from about five to ten per cent. of bromide of silver emulsion, and that this preparation is spread in a thin layer upon a glass plate, there is obtained a sensitive surface which is exposed to light under the negative to be reproduced. When it has been sufficiently exposed, the plate is washed in cold water, and there is thus obtained an image scarcely visible, furnished by the glue which has been rendered insoluble, and which can be coloured with suitably chosen colouring matters.

The bromide of silver is removed by a suitable solvent—hyposulphite of soda, for example.

This process gives, with the greatest facility, positives of all the colours with all the graduations of tints of the negative.

The colouring matter can also be added before spreading the sensitive substance on the glass or other support, and a complete positive obtained by simple washing in cold water.

The patentees' claims are:—1. The employment of bichromated mucilages soluble in a cold state to which suitable insoluble substances are added, for the production of photographic images without transfer, with all their demi-tints, these substances being afterwards eliminated by suitable solvents or allowed to remain in the layer, substantially as herein described. 2. In the photographic process herein described, the employment of gelatine and other mucilages soluble in lukewarm or tepid water, substantially as herein described. 3. The employment of the process without transfer herein described for obtaining proofs in colours upon glass, paper, or other support, by the successive impression on the same plate of three monochrome images obtained from three negatives, substantially as herein described. 4. In the production of photographs in colours, the employment of the process herein described.

RÖNTGEN'S PHOTOGRAPHY OF THE INVISIBLE.*

When electric sparks are caused to pass between terminals enclosed in a glass bulb, and the air is gradually removed from the bulb by means of a suitable pump, a series of phenomena present themselves to view. First of all, as I will now show you, as the exhaustion proceeds, the spark which, to begin with, was thin, broadens out into a description of flame; next the flame disappears, and the whole bulb becomes filled with pale phosphorescent light, the colour of which is dependent upon the nature of the residual gas. Bulbs exhausted to this degree, and containing different kinds of residual gases, are known as Geissler tubes, and in them the luminescence under the electric discharge is believed to be due to violent commotion and frequent collisions among the molecules of the residual gas, which, owing to the exhaustion, are much further apart, and are therefore much more free to move about than they are in the case of gases at ordinary atmospheric pressure.

If the exhaustion be continued considerably beyond the point to which Geissler tubes are exhausted, there is again a change in the phenomena. As will be seen in the tubes that I am now connecting, the small amount of air that still remains in the tubes is practically non-luminous, but the glass itself is now luminescent, more especially at a point which is directly opposite the plate terminal inside the tube that is connected with the source of negative electricity. Further, I will show you tubes in which certain phosphorescent substances—such as the sulphides of calcium and strontium—are placed inside the tube opposite the negative terminal or cathode, as it is called; and you will see that, under the influence of the discharge, these substances luminesce with great brilliancy, and with different colours, according to their material.

These tubes are Crookes' tubes, and it is to the labours and great experimental skill of Professor Crookes that we owe much of the knowledge that we have as to these phenomena.

As I mentioned to you, in order to produce luminescence in the phosphorescent substance placed inside the tubes, it is necessary that this should be directly opposite the cathode terminal, and the luminescence is, as a matter of fact, due to some form of emanation that proceeds in straight lines from the cathode terminal normally from its surface. That this is the case can be seen from the behaviour of the Crookes' tube that I will now put into operation. In this tube there is a screen of aluminium, in the form of a cross, which can be so placed as to be in the direct line between the cathode terminal and the glass. As you will observe when I turn on the electric current, the cross casts an intense shadow on that portion of the glass that it screens from the cathode rays. This tube also serves to show another phenomenon peculiar to these tubes. I will now remove the aluminium cross, and allow the rays to strike upon the whole surface of the glass; where previously there was a dark shadow of the cross, you now see a bright image of the same form. The explanation is this, after the glass has luminesced for a certain time under the action of the rays, it becomes fatigued, and until it has had a rest will not light up so brilliantly as before. That portion of the glass which, in the first experiment, was protected by the cross, is less fatigued than the remainder, which has been luminescing for a longer time; consequently it is now more brilliantly luminescent than the more fatigued portion.

The cathode rays are also capable of doing actual mechanical work. I have here one of Professor Crookes' tubes, which contains a small mill with inclined mica vanes similar to those used in Crookes' radiometer, The cathode waves, as you see, cause these vanes to rotate rapidly, making them at the same time luminesce with beautiful colours, due to the rare earths with which they are coated.

What the cathode rays really are is a matter of some doubt. The fact that they can be deflected by a magnet, as I will show you, seems to support the theory held by Crookes himself, and by most English scientists, that they consist of streams of electrified particles of matter, probably particles of the residual gas, which, being negatively electrified, are violently repelled from the negative electrode, and, being in this way projected across the interior of the tube, produce luminescence of the glass or other substances by their bombardment. It may be perhaps thought that the exhaustion in tubes of this description is so high that there cannot be a sufficient number of molecules of residual gas left to countenance such an explanation. According, however, to a calculation of Professor Lodge, and assuming the tube that I hold in my hand has ten inches cubical content, and further assuming the exhaustion of this tube is so good that only one hundred-millionth of the original atmospheric pressure remains, which I may say corresponds to about one 500th of an inch in a barometric column three miles high, assuming all this, there are still some sixteen thousand billion molecules of residual air left in the tube.

However, just as in medicine it is at present the fashion to attribute all diseases to microbes, so, especially among Continental scientists, it is now very fashionable to attribute most things to wave motions in the ether; consequently there are many eminent scientific men, both here and more especially abroad, who do not uphold the Crookes' theory of radiant matter, but who imagine that the cathode rays are more nearly akin to light or sound.

So far we have been dealing with what takes place inside the tube, and till a few years ago it was not known that, apart from the light that emanated from the tube and was visible to the eye, there was anything further. Some three years since, however, Lenard discovered the interesting fact that it was possible to bring the cathode rays outside of the tube by inserting in the latter an aluminium window. He had noticed that glass was exceedingly opaque to these radiations, and he argued that it was due to this that the radiations were not able to find an exit into the external vicinity of the tube. Lenard not only anticipated Professor Röntgen in this respect, but he also succeeded in obtaining actual photographic impressions through various substances by means of

* Continued from page 168.

the cathode rays. He noticed that some of these rays after they had left the tubes, were deflected by a magnet, and that others were not, that they appeared to pass without difficulty through many substances which, to ordinary light, were entirely opaque; in fact, he did some three years ago a large number of things which recently have been accepted by the public as entirely novel.

Röntgen, on the other hand, deserves the undoubted credit of having discovered what is certainly the most remarkable, and probably at present, the most useful purpose to which photography, by means of these radiations, can be put. He found that, owing to the fact that bones are more opaque to these radiations than flesh, it is possible by their means to obtain accurate pictures of the bones in the living body. It must be understood that these pictures—some of which taken by myself I will shorty throw upon the screen—are obtained without the use of any camera or lens. They are, in fact, merely shadow pictures. They differ, however, from the ordinary shadows that would be cast by the hand or other portion of the body being interposed between a source of light and a screen, in that with the Röntgen rays the bones cast a more dense shadow than the flesh, and are, consequently, visible through the latter on the developed photograph. Similarly metallic objects enclosed in a wooden box, or coins in a purse, cast more intense shadows than the wood of the box or the leather of the purse, and thus impress their images upon the photographic plate.

Further, it must be understood that Röntgen, in his experiments, employed no aluminium window to his tube, and it is a question whether his rays are really at all of the same nature, as Lenard's cathode rays, on passing through the glass walls of the tube, become converted into something else, or that a portion of them—that portion that is deflectable by a magnet—are, as it were, filtered out. In any case, the Röntgen rays have many peculiarities. They penetrate with little difficulty many substances which, to ordinary light, are quite opaque. They penetrate metals with difficulty, though all metals in sufficiently thin sheets appear to be more or less transparent to them. The heavier metals are most opaque, and aluminium, which is one of the lightest of metals, is one of the most transparent. They pierce most organic materials with ease, and, apparently, without much regard to their colour. For instance, ebony does not appear, in any appreciable extent, to be more opaque than pine. Ebonite, vulcanised fibre, black paper, and other substances which are entirely opaque to ordinary light, are exceedingly transparent to these rays, while glass, fluorspar, and other substances that are very transparent to light, to these rays are remarkably opaque. In fact, the opaqueness or transparency of substances to ordinary light is no guide whatever of their transparency to the Röntgen rays, and, as has recently been discovered by Professor Dewar, the true fact of the case seems to be that the transparency of substances to these rays is inversely proportional to the atomic weights of their elementary constituents. This connexion with gravity is most interesting, for, while on the one hand it supports the theory that these rays are not similar to light, but more resemble streams of minute projectiles which are more or less arrested in their course by the inertia of the particles of the target against which they are thrown, on the other hand, it has long ago been suggested that gravitation may be due to a longitudinal wave motion of the ether.

We invite the co-operation of our readers in rendering this feature of the* Journal *useful and instructive.*

Chlorophyll.—W. H. G. writes: "For various purposes, during the past few years, Mr. F. E. Ives has recommended the use of chlorophyll prepared from the leaves of the blue myrtle. As I notice that that gentleman is or was recently in this country, I should be extremely obliged if he could give me any information regarding the shrub in question, as I have made inquiries in various quarters without finding anybody who knows anything about it. Is it a native of America only? or, if it grows in this country, can Mr. Ives say by what name it is known here, as several nurserymen I have applied to do not know it by the name given above? Again, I should like to ask Mr. Ives if the virtue of the blue myrtle lies in its giving a product differing in spectrum qualities from ordinary chlorophyll, or whether it is only a richer source of that substance. Also, if I am not troubling him too much, I do not remember to have read a description of his method of preparing the chlorophyll solution. Is it necessary to extract the pure chlorophyll, that is to say, to free it from its waxy and other impurities, or will it suffice simply to draw out the colouring matter by digesting a quantity of leaves? If the latter will do, then I think alcohol or a mixture of alcohol and ether will be found preferable to ether alone, owing to the greater solubility of the chlorophyll in alcohol; but, if it is needful to remove the waxy constituents, the presence of alcohol will interfere with their ready separation. If Mr. Ives, or any other of your readers, could advise me on these points, I should be deeply obliged."

Colour Screens for Orthochromatic Work (To Mr. F. H. Burton).—"This gentleman, in an article, recently, alludes to the aqueous solution of chromate of potash as being, so far as at present known, the most reliable agent for cutting off the violet and ultra-violet rays. Which chromate of potash? The neutral, or the acid, or dichromate? These, as every one at all acquainted with chemistry knows, are salts of very different colours, the one being a pale lemon yellow, the other a deep red; and, though the latter, in *weak* solution, shows very little of the red colour, it is still strength for strength—in volume, at least—much deeper than the neutral chromate. Taking a solution of five grains of each in three ounces of water, which is about the strength recommended by Mr. Burton, it is necessary to dilute the bichromate to three times the volume before the colours of the two solutions approximate, when an ordinary china teacupful of each are placed side by side; but, if coffee cups be taken, then the bichromate is the darker. Similarly, owing to the much greater tinctorial power of the neutral chromate, the more the solutions are diluted, or the thinner the layer of solution, the darker, proportionately, does the latter appear—it falls off, in fact, to a far less degree than the bichromate. Independent, then, of the fact that the absorption spectra of two solutions visually apparently equally dense must vary more or less, it is important to be sure which of the two salts is to be used in the proportion of one to three hundred."—C. P. R.

Collodio Chloride Paper (To "Wet Plate").—You should find less difficulty in arriving at a solution of the problem you have set yourself than in preparing a paper to be toned in the ordinary way. There is not the least difficulty in preparing an emulsion that will give any desired degree of contrast, or that will work well with either thin or dense negatives, as may be required; but the difficulty is to get the image to tone well on the ordinary gold bath. That necessity removed, it is pretty plain sailing. A formula something like the following will answer:—

Pyroxyline	4 grains,
Calcium chloride	2½ „
Citric acid.....	3 „
Nitrate of silver	12½ „

to each ounce of ether and alcohol mixed in equal parts; that is to say, those are the contents of each ounce of emulsion. I presume "Wet Plate" understands how to mix them. With such an emulsion the development can be effected in the same manner as with gelatino-chloride, either with a preliminary soaking in bromide of potassium solution, or with such a solution as that recommended for Solio paper, containing a very large proportion of bromide. It is best suited for negatives of medium density, and may want a little modification for very thin or very dense ones. But that is too wide a subject for this column."—Syntax.

Films of Pure Silver Bromide (To Syntax).—"Latent images produced in films of pure silver bromide cannot be developed by the alkaline method. (See Cantor Lectures by Prof. Meldola, March 1891.) In a pure film of bromide, or in the case of a solid mass, such as "Syntax" describes, the whole of the

molecules are in contact with each other, and chemical reduction commencing in any one part of the film can spread throughout the whole, any image being thereby lost. In a gelatine bromide film, which contains a number of isolated particles separated from each other by gelatine, only such particles as contain a nucleus of light altered molecules are developable, and the action cannot spread beyond the confines of the particle. The image is therefore preserved. There is also another point to consider:—The effect produced by exposure varies according to whether a sensitiser is present or not. With gelatine there is little doubt that some small portion of bromide is actually removed from the bromide and absorbed by the gelatine which afterwards readily yields it up to the developer. The result is that even a very short exposure leaves a developable nucleus in the particle. If, however, no sensitiser is present, the bromine is not actually separated, but remains in the immediate vicinity of the light product, to which it is still, to a certain extent, attracted. It then acts as a powerful restrainer upon the chemical reduction of the light product, which, under these conditions, is reduced with as much difficulty as if it had never been exposed at all. Light alone may be considered to simply shake up the molecule of silver bromide, the atoms of which are loosened and rearranged in a different, but not necessarily developable, form. If, however, a sensitiser is present, it seizes the opportunity, afforded by the disturbance, to abstract an atom of bromide, and keeps it. The residue is then easily reducible. Fused silver bromide is, no doubt, much less sensitive, either to light or development, than a simple film, hence the difficulty experienced by 'Syntax' in producing any effect with a normal developer. The latent image on pure bromide of silver is developable by the physical or accretional method. The visible image is then built up upon the original latent image, which probably does not undergo any chemical reduction at all."—C. Welborne Piper.

I have just noticed one of your readers inquiring the best means of securing a situation as retoucher in Chicago. The problem with retouchers and others in the photographic business here is how to get out of it. Business is very, very quiet, and a good deal of my time is taken up advising people to keep out, or get out, according to circumstances.—A Scot in Chicago.

Foreign Patents.—W. W. says: "Would you kindly give me the following information:—I intend, in a few weeks, making provisional application for a patent. Would you kindly let me know the cost for America, France, and Germany, and if I can get provisional protection the same as for a British patent? Also, after having obtained a British patent, must I take out the foreign patents at once, or how long can I wait?"—The information our correspondent seeks is best obtained from a patent agent; but perhaps some of our readers may be able to supply it.

News and Notes.

Royal Photographic Society.—Technical Meeting. Tuesday, March 24, at 12, Hanover-square, at eight p.m. *The Relative Colour-sensitiveness of Ordinary and Isochromatic Plates*, with a demonstration, by Mr. F. E. Ives.

The Photographic Club.—The next weekly meeting of the Club will be held in the Club-room at Anderton's Hotel, Fleet-street, E.C., at eight o'clock on Wednesday evening, March 25. Travellers' Night. *Lincoln Cathedral*, with lantern illustrations, by Mr. Fred H. Evans. Afterwards a set of slides, by Messrs. R. W. Thomas & Co., Limited, illustrating their new anti-halation plate, will be passed through the lantern.

Mr. G. Abbott, of the Natural History and Philosophical Society, Tunbridge Wells, writes: "I forward you a programme of the Congress to be held here next April. Our main object is to bring about a union of all the scientific societies in the south-east of England. By this means it is thought that each Society could and would co-operate in many ways for mutual advantage. Photography is so important to all our natural history societies that I hope many of the amateur photographic societies may join us. We look forward to the time when the whole of the United Kingdom will be covered by such unions, under the immediate patronage of the British Association."

An International Exhibition of Photography, pictures, transparencies, apparatus-appliances, and photo-mechanical work will be held in the Great Hall of the Society Vereeniging, Harlem, Holland, from May 16 to 26, 1896, under the patronage of His Excellency Baronet J. W. M. Schrorer, Commissary of H.M. the Queen of Holland, and Baronet J. W. G. Boreel van Hogelanden, Mayor of Harlem, organized and managed by the Harlem Amateur Photographic Club. The International Committee consist of Messrs. Walter D. Welford, London; Ernst Juhl, Kunsthalle, Hamburg; Maurice Bucquet, Paris. Special notice.—All communications from British exhibitors must be made to Mr. Walter D. Welford, *Photographic Review* Offices, 15, Farringdon-avenue, London, E.C., who will supply forms and all information, and receive the entries, entry fees, and pictures.

On Saturday evening last the premises of Mr. J. R. Gotz, 215, Shaftesbury-avenue, were burglariously entered, and a half-plate Psycho camera and four lenses stolen. The matter has been placed in the hands of the Bow-street police officials. The numbers and description of the lenses are:—

Zeiss anastigmat, by Suter ..... No. 12,219, Ser. 1, 7·2, No. 5;
" " " ..... No. 12,213, Ser. 1, 7·2, No. 4;
" " " ..... No. 11,305, No. 2;
And Suter rapid aplanat, eight inches ..... No. 15,314.

North Middlesex Photographic Society.—This excellent and flourishing Society held its annual dinner at the Holbern Restaurant on Saturday, March 14. The President of the Society (Mr. J. C. S. Mummery) was in the chair, and among those present were the Rev. F. C. Lambert, Mr. Debenham, Mr. Chapman Jones, Mr. Child Bayley, Mr. Wall, Mr. Bedding, Mr. J. A. Sinclair, Mr. Golding, Mr. W. B. Goodwin, Mr. C. Beadle, and many other members and friends. The toasts included "The North Middlesex Photographic Society," "The Officers," "The Press," "The Visitors," &c. In the course of the evening the certificates gained at the recent Exhibition of the Society were handed to the winners by Mr. Lambert, who was one of the Judges.

The New Photography.—The hitherto unaccomplished task of passing Röntgen rays right through the human body has been performed by Dr. Hall-Edwards, of Birmingham, who, with an adult subject, has obtained photographs showing the backbone, with the vertebræ and the spinal cord in full detail. Dr. Hall-Edwards has, before the local postal authorities, successfully used X rays for detecting coins in newspapers, embedded in sealing-wax, and otherwise posted contrary to regulations. By the aid of the Salvioni Crytoscope objects were seen through hundreds of thicknesses of paper.—Mr. A. F. Stanley Kent, of St. Thomas's Hospital, working on the same lines as Professor Röntgen, has succeeded in transmitting the X rays completely through the body, and the condition of such organs as the kidney can be investigated. The photographs which have been so far taken show those portions of the body lying between the fifth rib and the pelvis, and there are distinctly visible in these photographs the bones of the pelvis, the spinal column and the lower ribs. The space occupied by the kidney itself is slightly more transparent in the negatives, thus indicating that the kidney itself is rather denser than the surrounding tissues. As there seems some doubt as to the opacity of the renal calculi, Mr. Stanley Kent took photographs with a view to clear up this point. It was found that, although there is a considerable difference in the relative transparency of the different stones, all of them are sufficiently opaque to render it possible to differentiate them clearly from the surrounding tissues.—Mr. Edison professes, according to a Dalziel's despatch, to have discovered a chemical substance—out of one thousand eight hundred which he tried—which enables the Röntgen shadows to be seen directly by the naked eye, with the result that the physician may soon be able to study his patient alive as he now does at an autopsy. In practice the patient would stand between the apparatus and a screen, out of sight of the physician so far as the ordinary light is concerned, but his skeleton would be revealed on the crystal side of the screen, and the fat and muscles would be indicated by variations in the density of the shadows. Physicians will, Mr. Edison asserts, be able even to trace the presence of consumption, because of the difference in solidity shown by the diseased and healthy parts of the lung. He declines to divulge the nature of his chemical.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

March.	Name of Society.	Subject.
23	Croydon Camera Club	Rehearsal of Slides to be shown on 25th.
23	Lantern Society	*The Scottish Alps.* W. Laymond Hewie.
23	North Middlesex	*Photography and Book Illustration.* A. J. Johnson.
23	Richmond	Demonstration. P. Broomhall.
24	Brixton and Clapham	*Retouching, and the Improvement of Negatives.* Part II. Landscape Negatives. R. C. Whiting.
24	East London	Platinotype Printing by the Company.
24	Hackney	*Trip to Lucerne and Venice.* W. Fenton Jones and others.
24	Royal Photographic Society	*The Relative Colour-sensitiveness of Ordinary and Isochromatic Plates.* F. E. Ives.
25	Borough Polytechnic	General Meeting.
25	Croydon Camera Club	Twenty-fifth Public Lantern Show.
25	Leytonstone	Members' Lantern Evening.
25	Photographic Club	*Lincoln Cathedral.* Fred H. Evans.
26	Ashton-under-Lyne	*A Ramble in Far Lochaber and Ultima Thule.* Dr. A. Hamilton.
26	Bradford	Members' Quarterly Competition.
26	Ireland	Photograph o Topics.
26	Leeds Camera Club	*The Chemistry of Photography.*—IV. Lantern Slides. Dr. J. T. Thresh.
26	Leigh	Lantern Evening.
26	Liverpool Amateur	*Five Hundred Miles up the Nile.* David Lewis.
26	London and Provincial	Lantern Evening.
26	Oldham	*Round about Crowland.* J. Chadwick.
26	Woolwich Photo. Society	*Mounting and Framing.* J.C.S. Mummery.
27	Croydon Microscopical	Conversational Meeting.
27	West London	Members' Lantern Evening.
28	Birkenhead Photo. Asso.	Social Evening and Lantern Lecture. The President.

ROYAL PHOTOGRAPHIC SOCIETY.

MARCH 17,—Photo-mechanical Meeting,—Mr. C. E Hearson in the chair

Mr. T. BOLAS exhibited a print made in 1842 by Mr. Palmer, then of Newgate-street, by his "intaglio autographic process" (patent No. 8987 of 1841), a process which was almost identical with

PROFESSOR HERKOMER'S "NEW ART."

Mr. Bolas said that, as he understood the matter, Professor Herkomer's only claim for advance on, or variation from, the method of Palmer was, that, in making the painted image conductive of electricity, he dusted it with a roughening powder which was auto-discriminative—discriminative, presumably, of the spirit or intention of the artist; but, if the Professor could fully establish this property of his powder, he would have made the first step towards a "new science"—experimental psychology—for which he would win greater fame than for his "new art." The specimen shown was one of a series painted upon silvered copper plate, by Lance, and electrotyped by Palmer in 1842, and appeared to Mr. Bolas to possess every good quality to be found in Mr. Herkomer's work, and with the advantage of reproducing the actual touch and texture of the artist's original, and this without the use of any mechanical or other discriminative device. The marvellous play of gradation obtainable by Palmer's method suggested the value of its application to the retouching of the reverse upon which an intaglio photographic plate was electrotyped, and Palmer's specification would well repay perusal. The print appeared to have a wider and fuller range of tone than was obtainable by the new art; the use of a discriminating powder (so called) only resulted in a less successful print, and Mr. Bolas thought that, in so far as Professor Herkomer's method was new, it was so much the worse. For a powder to discriminate was a miracle, a new fact in metaphysics.

CAPTAIN COLLARDON described various methods of producing

IRREGULAR GRAIN WITHOUT SCREENS.

The first method was based on the reticulation of gelatine. Autotype tissue, sensitised in a bath of three per cent. bichromate of soda and three per cent. bichromate of potassium, dried as quickly as possible, in contact with a talced glass, at a temperature of from 29° to 30° C., exposed under the negative, and immersed in water at 19° or 20° C. for about forty seconds, and here the reticulation of the gelatine was under complete control, and the longer the immersion the coarser would be the resulting grain. The copper plate was dusted with a mixture of two parts of colophony and one part each of mastic and sandarac, and the carbon tissue was then squeegeed upon it. In the second method, white lithographic ink, mixed with gold size, and thinned with turpentine, was distributed, by means of a perfect gelatine roller, over the surface of a fully exposed thin negative. The nature of the grain caused by this operation would vary with the manner in which the plate was rolled and cross rolled, and the grain could be applied, if desired, to particular parts of the negative. When the ink was dry, the negative should be varnished, and the print on carbon tissue squeegeed to a plate, dusted as in the beforementioned process. A further method consisted in coating a plate with a soft gelatine and bichromate, exposing under a negative, soaking in water, and inking in without drying. Prints produced by each of these methods were passed round for examination. Referring to the subject of

COLOUR PRINTING,

Captain Collardon showed a print in colours, produced by a process which, he said, had been invented by an Italian gentleman, and by means of which pictures in any number of colours could be made at the rate of about six hundred an hour in two printings only and in unlimited numbers, all the colours being printed together from one plate in the first operation, and a key-block in brown, sepia, or black, by the second. The machine was at present made to work up to forty-two inches, but no difficulty was anticipated in producing much larger prints. It would be possible to reproduce on a single page of an illustrated newspaper as many as half-a-dozen pictures of different character, and each of several different colours—a wash drawing, a water colour, an oil painting, &c.—and to print them all together and in but two workings. Captain Collardon said he had actually seen the machine at work, or he would not have believed such a thing was possible; a part of it was covered up when he saw it, as the patent was not completed, but he understood the process was quite novel and entirely unlike any method at present known.

Some speculation ensued as to the method by which the colour print had been produced, and Messrs. Ives, Gamble, and Bolas made some remarks as to the advantages arising from the use of screens with broad black lines, the general opinion appearing to be that such screens, while transmitting comparatively little light, gave greater control over gradation than more open screens.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

MARCH 12,—Mr. A. Haddon in the chair.

The CHAIRMAN, in reply to Mr. Beckett, said one could send a ten-inch spark through a ten-foot tube, provided the vacuum was not perfect. A perfect vacuum being a non-conductor of electricity, if the air in a tube were rarefied as far as possible, one could bring the terminals to within one-tenth of an inch without any result.

COLOUR SENSITISING.

The following question from the box was read:—"Where is there to be found instructions for sensitising dry plates for various separate colours?"

It was stated that Eder's work, *Ausführliches Handbuch*, Hübl in the *Correspondenz*, and several German works and English translations, gave instructions for doing this.

THE STIGMATIC AND DALLMEYER-BERGHEIM LENSES.

Mr. T. R. DALLMEYER, speaking of the Stigmatic lens, showed four test negatives, one taken with an ordinary portrait lens made from the old glass in which it was impossible to eliminate the curvature of field at the same time as the astigmatic error, and the other three taken with different sizes of the Stigmatic lens, made of the Jena glass, having an angle of about 60°. In the first negative distinct indications of astigmatic error were noticeable in the corners, while in the others this had been eliminated throughout. With the new Jena glass, he said, opticians had been able to get rid of both curvature of field and astigmatism. He explained by diagram how Piazzi Smyth succeeded in doing this by the use of a strong negative lens just in front of the sensitive plate, and how he discovered the method. He considered the new Stigmatic lens an advance on anything done, and that the calculations involved were very pretty. It was, *per se*, a portrait lens. He was quite prepared to say that, for a group, a lens, with slight curvature of field, if free from astigmatism, was an advantage. However, the scientific acme was to free a lens from that. In answer to a query, he said the lens must be used as a whole.

The HON. SECRETARY asked what was the rule for calculating the position of the stop in order to avoid ghost or flare. He said Miethe had stated that, if the flare was four times as great as the lens, it did not matter.

Mr. DALLMEYER said there was really no rule, and that it was an extremely difficult calculation. He described a simple optical test. Ghost and flare were very different things.

The HON. SECRETARY quoted from the Zeiss patents, in which a fraction of the focus was given as the position for the stop, and asked whether it was a complex calculation.

Mr. DALLMEYER replied yes, but, as a matter of fact, it was more or less arbitrary.

The HON. SECRETARY asked if there was any rule with regard to rapid rectilinears and flare spot.

Mr. DALLMEYER stated it was best to place the stop almost at the optical centre of the whole combination. Speaking of the Dallmeyer-Bergheim lens, he thought Mr. Bergheim had done a very great service to photographers who wished to produce work that, to them and a good many others, was distinctly artistic, and he hoped they would be grateful to him for his work. The construction was one in which there was a meniscus lens, the barrel-shaped distortion of which was cured by a negative lens at the back, the diaphragm being in front. Regarding achromatism, this lens was not achromatic. Both lenses were made of one kind of glass, and purposely left so. Mr. Bergheim had said that, from his own experience, he thought that the lack of perfect achromaticity was an advantage, in that the image was somewhat prismatic. Another feature was in the separation of the lenses, which produced very varying foci, ranging from thirty-six inches to sixty inches in the one instrument. Mr. Bergheim's main object was to do away with the retoucher's art, and attention was called to the texture in some specimen photographs handed round, all the detail being given in a softened degree without destroying the structure.

Mr. W. E. DEBENHAM did not think justice had been done to the new Stigmatic lens. When he first saw it he considered it was the one important advance in portrait lenses since the time of Petzval. We have been calling out a long time for flatness of field, although a good deal had been got by putting up with a fair amount of astigmatism. The work we had to do generally was such as would be best done with a flat-field lens, and he thought the lens a vast improvement.

The HON. SECRETARY, speaking of the necessity for flat or round-field lenses, thought you must suit your lens to the work to be done. He doubted whether one could get a lens to do everything. He had been wanting a lens which would also remove those intrusive inequalities, such as wrinkles in a photograph, which he had not got with an ordinary lens, and the nearest approach to it was an uncorrected spectacle lens.

PHOTOGRAPHIC CLUB.

MARCH 11,—Mr. Foxlee in the chair.

Mr. Freshwater showed some interesting photographs which he had made with the X rays. The special feature about these latest productions of the New Photography consists in the fact that a much larger amount of detail is delineated than in former efforts, and also that the necessary exposure has been very much reduced. This acceleration of the exposure has been effected by a modification in the radiant matter tube. Messrs. Newton & Co., who are the manufacturers, have elaborated and worked out an idea due to Mr. Herbert Jackson, of King's College. The new tube is called a focus tube, and, although perhaps, strictly speaking, this is a misnomer, yet, by an ingenious arrangement of the terminals, the light is apparently directed in such a manner as to give much crisper images than does the older form of lamps. A coil sufficient to give a two-inch spark will, with the new focus tubs, emit sufficient of the new X rays to make an exposure in the average time of two minutes at a distance of five inches from the object to be shadowgraphed. With such a current there is no noticeable heating of the tube, and there is no occasion for intermittent exposure due to the tiring of the tube.

Mr. BRIDGE asked if the sharpness did not depend in a great measure upon the distance of the discs from the tube, viz., the longer the distance the sharper the image.

Mr. FRESHWATER said no, he thought not.

Mr. ISENTHALL, however, who had been making many experiments, agreed with Mr. Bridge that it was not possible to get such sharp results if the tube was too close.

Mr. Freshwater's results, which included a radiograph showing a needle in a lady's hand, and a mossy growth upon the bones of a man's hand, the skeleton of a mouse, the foot of a chicken, and also the details of a broken arm which had been improperly reset, were thought to be advances upon previous efforts.

The CHAIRMAN congratulated Mr. Freshwater upon his success, and thanked him in the name of the meeting for his very interesting results.

Mr. FRESHWATER then, in an informal manner, described his method of stereoscopic projection by means of coloured slides and properly coloured

viewing lorgnettes. He brought with him a considerable number of the latter, so that the members present had a unique opportunity of trying the method.

A series of Mr. W. D. Welford's lantern slides concluded the evening's work.

Brixton and Clapham Camera Club.—March 10, Mr. J. W. Coade (President) in the chair.—A discussion on

HAND CAMERAS

was opened by Mr. W. FRASER, who said he had read almost every book published on the subject, but had not found them of much assistance, as no two writers agreed upon the best form of camera to adopt, or the most suitable plates to use, one advising the most rapid obtainable, and another a comparatively slow plate. He then described the different types of hand cameras, and discussed their respective merits and demerits, and also those of various changing arrangements, shutters, finders, &c. He thought a rectilinear best for hand cameras, but a good single lens was much cheaper, and yet capable of turning out excellent work. He also showed a novel changing magazine of his own making. This took twelve plates in sheaths, and appeared absolutely certain and reliable in its action. As no patent was applied for, any one could copy it who desired. The discussion was taken up by Messrs. Biddell, Welham, Whittard, Kidson, and others, and many members brought hand cameras for inspection by those interested.

Camera Club.—March 12.—The meeting was unusually interesting, and, although there was only one subject announced for demonstration and discussion, that one eventually expanded itself into a many-headed two. Dr. Bowles was announced to give an account of some

PHOTO-ELECTRICAL EXPERIMENTS

which have recently been made by Lord Armstrong, and, as this part of the evening's work was concluded at a very early hour, it resolved itself into little more than the exhibition of a couple of dozen lantern slides, with short explanations of each picture. Dr. BOWLES filled up the rest of the available time with a description of some observations of his own, which were no less interesting. First, with regard to Lord Armstrong's experiments. These related to self-registered pictures of the brush discharge from a Wimshurst electrical machine, pictures taken in a dark room, without camera or lens, by bringing the electrodes over a highly sensitive gelatine plate. Very beautiful figures are produced in this way, endless variety being secured by varying the conditions under which the electricity was allowed to impinge upon the plate. By placing wires under the insulated plate, and causing those wires to carry an induced current, other effects are secured, and these are varied again by altering the positions of the electrodes. Another class of pictures was produced by covering a waxed glass plate with a very delicate layer of dust, the discharge urging that dust into all kinds of wonderful fret-work-like patterns. It was a pity that details of the method were not given by Lord Armstrong, for the lecturer laboured under the disadvantage of not having seen the experiments actually performed, and could not therefore satisfactorily answer the various questions concerning them with which he was assailed by the members of the Club. It was, however, understood that in connexion with the Wimshurst machine employed were two large condensing jars, and that it was the discharge from these, taken at the brush stage, and just before the tension had risen necessary for a spark discharge to take place, that was utilised. Some of the pictures resembled those taken some time ago under nearly similar conditions by Mr. Campbell Swinton. Dr. Bowles then proceeded to give an informal lecture upon certain observations which he had made with regard to

THE PENETRATIVE ACTION OF SUNLIGHT,

and he suggested that there was sufficient analogy between the results which he had arrived at and the action of the Röntgen rays to lead to the belief that the latter are but a modification of the actinic rays with which photographers are so familiar. The rays which afford heat, light, and chemical action are very different to one another, but not more different than they are to the Röntgen radiations. A great deal is made of the circumstance that the X rays are not refrangible. But are we right in assuming this to be a settled fact? May it not be that we have not yet hit upon the right substance to refract these unseen rays? Dr. Bowles then went on to say that for fifteen years he had been investigating the effect of light upon the human body, and especially the effect of light reflected from snow in penetrating the human skin and affecting the tissues beneath. He had come to the conclusion that what we call sunburn was not caused by heat alone, but that it was due far more to the violet, or ultra-violet, rays reflected from snow, water, mist, and other bodies. Captain Abney had found that these rays are very strong at high altitudes, and believed that altitude had much to do with sunburn. But he (Dr. Bowles) was sure that altitude alone could not explain sunburn, for one may remain unburnt on rocks at 10,000 feet and be immediately burnt on a glacier 4000 feet lower down. Not only does the skin get brown, but the wooden *châlets* get browned right through, the wood in extreme cases being actually carbonised, as he showed by a specimen which he had brought from the Alps. He believed that sunburn was caused almost entirely by reflected light, and that some hitherto unexplained physical change must take place in the light during or after reflection. He could not help feeling that there was a strong affinity between the Röntgen X rays and the actinic rays, which he had known had such powers of penetration. Dr. Bowles' remarks aroused much interest, and many of his observations were corroborated by Alpine climbers who were present, one of whom asserted that he never suffered more from sunburn than on a particular misty day, when the sun never showed its face. The meeting, which was under the chairmanship of Mr. Inwards, President of the Meteorological Society, closed with the usual vote of thanks.

Gospel Oak Photographic Society.—March 9.—This Society held an Exhibition of members' work in the Lecture Hall of the Gospel Oak Congregational Church, which was very well patronised. There were three classes, viz., (A) Portraiture and Figure Studies, (B) Landscapes and Seascapes, (C) Various. The prize-winners were:—Class A, first prize silver medal, Mr. Gittens; second, Mr. Pridham. Class B, first prize, hand camera, Mr. Bamber; second, Mr. Beyer; third, Mr. Davies. Class C, first prize, Mrs. Gittens; second, Mr. Rayner. Not the least feature of the Exhibition was the manufacturers' stall, which attracted a great deal of attention, and thanks are due to the following firms, who kindly lent their specialities:—Messrs. Thornton & Pickard, Horne, Letts & Co., Eastman's, Cresco Fylma, Wynne, Higgins, Wheeler, Tylar, Wellington & Ward, Paget Prize Company, Ilford, Elliott & Son, and Wray.

Hackney Photographic Society.—March 10, Dr. Gerard Smith presiding.—A large number of members and visitors assembled to hear and witness a lecture and demonstration on

RÖNTGEN'S X RAYS

by Mr. J. E. GREENHILL. In the course of the lecture some striking experiments were performed, and Mr. Greenhill's exposition was most lucid. A very brief summary is as follows:—Dealing with the subject of light, the lecturer said that at one time but little was known of the invisible part of the spectrum; the heat rays at the red end, and the ultra-violet rays at the other, together with the fact that these ultra-violet rays could be rendered visible or fluorescent by means of sulphate of quinine, comprised almost the whole knowledge of this particular subject up to a comparatively recent date; but the improvements in apparatus had helped to open up to later investigators an extended field of discovery, and it had been found that the visible part of the spectrum was but one-twelfth of the whole. The announcement of the discovery of the X rays had led to some controversy as to who was the first to discover their peculiar properties, and he would say in passing that there was a tendency in the times to claim a monopoly in discoveries or investigations. This was regrettable, for a true scientist should be of no nation; if he were not cosmopolitan, he was no scientist at all. Many erroneous statements had been made concerning the new rays, and hap-hazard conclusions drawn from insufficient experience of the subject. Indeed, seeing how recently the matter had first attracted attention, and the necessarily limited knowledge gained since, it was premature to pronounce on it with any positiveness; so, in describing the X rays, he would prefer to say no more than this: They are invisible, and are rendered visible by fluorescent substances, just as are the ultra-violet rays by means of sulphate of quinine. Placing a vacuum tube in the circuit of a Ruhmkorff coil, the turning on of the current caused the tube to be filled with a beautiful radiance—bluish, or violet—and most abundant at the end which held the negative pole terminal, or cathode, and yellow, and in small quantity only at the positive pole end, or anode. Mr. Greenhill showed how these cathodic rays had the same effect as ordinary light upon a radiometer. These cathodic rays were, however, not X rays, for the latter could not be produced in an ordinary vacuum tube, as the exhaustion was not high enough. A tube for the production of these must be exhausted of all but one-millionth part of its original air contents. With regard to the apparatus necessary, it was a mistake to think that very powerful and expensive electrical appliances were necessary. The best work could be done by means of a coil costing from 5*l.* to 10*l.* It was necessary to use accumulators for steady work; he knew of no primary battery suitable—all were so soon polarised. Whatever were used, the current must be strong enough to overcome the resistance of the coil. Concerning the tubes, he cautioned would-be experimenters against buying expensive tubes without having them properly tested. Newton's new Focussing Tube was a great improvement on others, and he had been using one lately with great success. Speaking of his first experiments in connexion with the subject, Mr. Greenhill said that his first successful result had been produced in one hour. In his later attempts he had reduced the exposure with superior results directly in proportion to the decrease until three minutes were reached, when the most successful results were obtained. He had found the most suitable dry plate and developer for this work to be the Cadett Lightning plate and the Velox developer. He had tried hydroquinone, but this was too slow. With the Velox, detail flashed up at once, and full density was obtained in five minutes. So much had been done nowadays in making plates sensitive to different rays that it was not too much to hope that in due course an emulsion would be made which was most highly sensitive to the X rays. Having shown some very fine negatives of the shadows of various objects, Mr. Greenhill proceeded to demonstrate. The fixed data of the experiments that evening were: Newton's focussing tube, a two-inch Ruhmkorff coil, a current of ten volts and ten ampères from accumulators, Cadett Lightning plates in black negative envelopes, and Velox developer. Mr. William Rawlings undertook the task of developing the exposed plates. All being ready, various articles, such as a razor in case, fountain pen in case, leather purse, bunch of keys, &c., were then laid upon the plate, enclosed in its envelope, and exposed for one minute to the rays from the tube, which was placed about five inches above. On development, the results were most successful. Every detail of the articles was shown in various degrees of intensity, corresponding to the resistance which the particular substance opposed to the passage of the rays. Particularly noteworthy were the chasing on the surface of the vulcanite penholder and the threads of the screws which held the parts together. The Chairman, having submitted his hand for experiment, an exposure of five minutes was given with most successful results, not only the shape, but the structure, of the bones being shown. A negative was also taken of a frog with three minutes' exposure. The results were excellent as regards the skeleton, but it was evidently over-exposed. One minute's exposure would have been quite sufficient. Several other plates were exposed beneath different objects, the results in every case being perfect. During the demonstration Mr. Greenhill replied to a number of questions which were asked him by those present. Speaking of the relative penetrability of different substances to the X rays, he said that hard vulcanite was most easily pierced. Among metals aluminium offered the least resistance, and lead about the most. Gold and silver were fairly easily penetrable. In his concluding remarks to those desirous of investigating these phenomena, Mr. Greenhill urged the necessity of proceeding on exact scientific lines. Desultory experiments were useless, and led to false conclusions. The Chairman, in proposing a vote

of thanks to Mr. Greenhill, voiced the opinion of all present in expressing the pleasure it had been to hear so clear an exposition, and to see such successful results. Personally he was inclined to think that these X rays would be found of more use medically than he had at first thought. If it could be found possible to show the structure and conditions of the organs in the thicker parts of the human body, the benefit would be great.

Woolwich Photographic Society.—March 12, Mr. E. Gibbs Kimber presiding.—Mr. J. MILLER, of the South London Society, gave a demonstration on

THE PREPARATION OF MIRRORS FOR PHOTOGRAPHIC PURPOSES.

He commenced by impressing upon his hearers the necessity of cleaning the glass before placing in the silver solution for coating. This he overcame by cleaning it first with nitric acid, and then with caustic potash, after which he placed it in a dish containing distilled water, his object being to keep it quite moist until the final operation. Mr. Miller had mixed up separately silver nitrate, 20 grains, to each ounce of water, and caustic potash, 20 grains per ounce, and a sugar solution made up as follows:—Loaf sugar, 1700 grains; distilled water, 20 ounces; pure nitric acid, 2 drachms; boil for ten minutes in a Florence flask or enamelled cup; when cold, add pure alcohol, 10 ounces, and distilled water to 80 ounces. From these the silvering solution is made as follows:—Two ounces of silver nitrate solution are taken, and to it strong ammonia ·880 is added drop by drop, until the precipitate first formed disappears (vigorously stirring with a glass rod all the time), and the solution is perfectly clear; to this is added 2 ounces of the caustic potash solution, then more drops of ammonia until again clear, and finally a few drops of the nitrate solution until a slight discolouration is noticeable; 3 ounces of this is then taken, and 3 ounces of water added, and 6 drachms of the sugar solution, 1 drachm to each ounce; when this is mixed, the glass to be silvered is taken out of the water and placed in another glass dish face downwards, and the solution poured on. In about twenty minutes or half an hour the solution will have become muddy; this denotes it has done its work, and, upon removing the glass, it will be found to be beautifully silvered on both sides, as well as the inside of the glass dish in which it was done; the glass can then be dried, and polished with leather and rouge, a splendid mirror being the result. Mr. Miller then showed a kind of frame made at an angle of 45°, in one side of which the mirror could be placed, and in the other a lens, the arrangement being used for taking reversed negatives, so much required in process work. The glass required for this must be optically ground, the piece used costing about 5*l.*, although not so large as a half-plate. But the lecturer had succeeded in making some half-dozen or so mirrors out of ordinary plate, one of which far surpassed the optically ground piece, but to obtain these he had been obliged to coat some dozens of pieces.

Birmingham Photographic Society.—March 10, Mr. Cossins in the chair.—Mr. HAROLD BAKER gave a demonstration on

BROMIDE PRINTING AND DEVELOPMENT.

Mr. BAKER, in speaking of development, said that the modern developing agents, such as metol, amidol, and quinol, were superior to ferrous oxalate on account of the absence of iron, which, it was well known, could not be removed from paper, even if boiled in strong hydrochloric acid. Exposures were made from negatives of varying densities on Ilford slow and rapid papers, and developed with metol and "Harold Baker's developer."

Liverpool Amateur Photographic Association.—March 12, Dr. J. W. Ellis (Vice-President) in the chair. Mr. ST. C. CRAWLEY gave a short paper and a practical demonstration on

PHOTO-MICROGRAPHY.

The necessary apparatus which is required, in addition to the microscope, is of a simple nature, and was fully described. Mr. Crawley then proceeded to enlarge a microscopic section of ash wood to about 275 diameters, using an isochromatic plate, which was afterwards developed and handed round for inspection.

Oxford Camera Club.—March 9.—A demonstration of

PHOTOGRAPHY BY MAGNESIUM LIGHT

was given by Mr. E. A. RYMAN-HALL, one of the Vice-Presidents of the Club. To add interest to the proceedings, members were invited to bring cameras, an invitation of which several availed themselves. The Chairman of the evening (Colonel Impey) allowed himself to be posed before the cameras, three exposures being made. Two flash lamps were used in each trial, but, in the first exposure, one rather hung fire. The lecturer advocated as large a flame as possible, to give a more even lighting than possible with a small flame. After the exposure some of the plates were developed with satisfactory results.

Rotherham Photographic Society.—Annual Exhibition, March 10, 11, and 12.—This annual event (the seventh) was held in the St. George's Hall, Rotherham. Some 600 prints were displayed on the walls, and of this number about 500 were the work of members. Contrasted with the previous year, the quality showed only slight improvement; in fact, a more judicious weeding out would not have taken from the effectiveness of the Exhibition. It was noticeable that carbon and platinotype did not seem to be much favoured, the principal run of process being the gelatino-chloride. In quite a number of instances really good examples would have been still better by the adoption of a more suitable printing method. Landscapes very largely predominated, and there were a goodly number of bromide paper enlargements. Turning to individual effort, prominence has to be given to the examples sent in by Mr. R. Chrimes, jun., Miss M. Crossley, Mr. G. T. M. Rackstraw, Dr. Baldwin, Mr. W. H. Haywood, Mr. R. H. Law, and Mr. H. Smith. Mr. James Leadbeater had followed somewhat upon the lines of former years, when he produced the interesting series of photographs of frost on window panes. His latest efforts have been the rendering of crystals of various salts, the results being most marked. A big contribution of photo-survey prints also found a place. There was a fairly large loan collection, including specimens from the Autotype Company, London; Mr. C. B. Keene, F.R.P.S., Derby; Mr. W. G. Fox, a member (pen-and-ink sketches); Messrs. West & Sons, Southsea; and Messrs. Marion & Co., London. The opening ceremony was performed by Major Stoddart, J.P., the Chairman being Alderman J. Mason. The visitors included the Mayor and Mayoress of Rotherham (Mr. and Mrs. E. Hickmott), Lady Albreda Bourke, the Hon. Mabel Fitzwilliam, and the Hon. Theresa Fitzwilliam. The last three ladies were exhibitors. On each evening there were special attractions. Music was furnished by the Eastwood Orchestral Band and a party of glee singers. On Tuesday *Amateur Photographer* prize slides and Messrs. Wilson's *Ruined Temples of the Nile* slides were shown. On Wednesday the slides were scientific, including Röntgen, astronomical, frost, and salt-crystal photographs. Thursday night's slides were those of members. Mr. Leadbeater manipulated the lantern, and the Hon. Secretary gave the descriptions. There were crowded attendances on all the days, and it is expected the financial results will stimulate the Society to still greater things.

Kilmarnock and Ayrshire Photographic Society.—March 13.—Mr. J. Mack Wilson presided. Mr. T. H. STRINGER, the representative of the Platinotype Company, London, gave a demonstration on

PLATINOTYPE PAPER.

The absolute permanency of the paper and the facility with which it can be handled render it an exceedingly suitable paper for photographers. Among other things, he showed an ordinary print on the Platinotype Company's A.A. paper. This was mounted on a cut-out mount while slightly damp, so that, when quite dry, it was quite tight. The mount, with the print, was then placed in a frame and, instead of the ordinary backing, a sheet of ground glass was inserted. This, when held up to the light, had all the effects of an excellent transparency, and yet, when placed against a wall, had the appearance of an ordinary photograph. The one which Mr. Stringer showed to the audience was most pleasing. About sixty views, taken from negatives on Thomas's well-known anti-halation plates, were shown, and they certainly justify the use of anti-halation plates for interiors, not a trace of halation being seen, which is always more or less in views of interiors taken on ordinary plates. The views of the Albert Memorial Chapel and the Royal Mausoleum had been obtained by the special permission of Her Majesty the Queen, and they are believed to be the only ones extant. Mr. A. J. Thompson, Ayr Academy, and the Secretary, Mr. William Patterson, Newton Academy, Ayr, showed over two dozen slides from snap-shots taken at the Ayrshire teachers' picnic last summer. Mr. Maloni showed slides from negatives taken by his patent light at dances in the Town Hall, Ayr. This invention of Mr. Maloni's is admirably adapted for the purpose intended, viz., the photographing of people at their own houses in the evening.

Ulster Amateur Photographic Society.—March 9, Mr. Wm. Gray, M.R.I.A., in the chair.—M. ALEX. TATE, C.E., occupied the first portion of the evening with an extremely interesting account of the

PHOTOGRAPHIC CONVENTION OF THE UNITED KINGDOM.

He said, in his opening remarks, that the Convention was founded in the year 1886, mainly through the influence, and at the instigation of, the late Mr. J. Traill Taylor. It had been long felt that something more was needed than was supplied by the Royal Photographic Society and the various other photographic societies scattered all over the kingdom, in order to bring all orders and classes of photographers—professional, manufacturing, and amateur—into communication with each other for the advancement of photography in all its branches, the promotion of a friendly interchange of ideas, and the forming of a personal acquaintanceship among the workers in this science. The idea soon took shape, and the Convention was the result. It is governed by a President and Council of forty members, elected at the annual meetings held in various centres. Meetings have been held in Derby, Glasgow, Birmingham, London, Chester, Bath, Edinburgh, Plymouth, Dublin, and Shrewsbury, each one generally lasting a week, during which time prearranged excursions are made during the daytime to neighbouring places of photographic interest, while in the evening meetings are held for the reading of papers, with discussions thereon, and lantern displays. As illustrative of the kind of results obtained through the Convention excursions, he showed on the screen about 150 slides, many of them his own taking, and others supplied through the courtesy of Mr. R. P. Drage, the able Hon. Secretary of the Convention, the work of Mrs. Snowden Ward, Messrs. W. D. Welford, Teape, Hepworth, and Seaman, all well-known experts in such matters. In his concluding remarks, Mr. Tate hoped that the date was not far distant when the Convention would be invited to make Belfast a centre for one of its annual meetings, and he had great pleasure in bringing the suggestion before our local photographers for their consideration.

Patent News.

THE following application for a Patent was made between March 4 and March 11, 1896:—

KINETOSCOPIC PHOTOGRAPHY.—No. 4686. "Improvements in Apparatus for projecting Kinetoscope Pictures on the Screen." R. W. PAUL.

Correspondence.

☞ *Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

THE NEW PHOTOGRAPHY.

To the EDITORS.

GENTLEMEN,—Great improvements have been made during the past few weeks in the Röntgen photography, and the process has now been sufficiently developed to render it of practical value in surgery and medicine.

Its successful application, however, requires expensive apparatus and special appliances, the working of which necessitates some technical knowledge.

Under these circumstances, acting on the advice of several eminent physicians and surgeons, I have decided to establish at this address a laboratory specially devoted to the purpose.

This will be equipped with the most improved apparatus, which will be added to as experience and experiment show to be advisable.

The work will be carried out under my supervision by one of my assistants, Mr. H. L. Tyson Wolff.

It is hoped that these arrangements will prove of service to medical men who may desire to have the process applied to their patients.

The laboratory will, it is expected, be in working order in the course of a few days.—I am, yours, &c., A. A. C. SWINTON.

66, *Victoria-street, S.W. March* 11, 1896.

RÖNTGEN RAYS: PLATES AND GAS CYLINDERS.

To the EDITORS.

GENTLEMEN,—Although displaying much ignorance, I risk the following questions. If shadowgraphs can be obtained by sunlight, magnesium, the light from a paraffin lamp, and *without any light at all* (in the ordinary acceptance of the term), what would be a safe and Röntgen-rays proof method of packing or storing our dry plates? Are these rays in any measure answerable for unexposed plates being found to be fogged? Another question occurring to me is this, Would not the Röntgen rays prove a practical means of testing compressed gas cylinders, to show whether or no the steel is uniform in substance, and if it contains any flaws or undesirable inequalities? Any information will be welcomed and appreciated at least by—yours, &c.,

Kilburn, London, N.W. FREDERICK W. MUNCEY.

THE ARTIGUE PROCESS.

To the EDITORS.

GENTLEMEN,—I gather from the remarks under "By the Way" in your last issue but one, that the writer is not altogether enraptured with the general results he has seen by the Artigue method championed by Mr. Maskell. Personally, I do not propose criticising these, as clearly we both agree that, if Mr. Maskell obtains the results he seeks by this method, and is satisfied, no one has cause to complain; my object, however, in writing is mainly to correct an error stated under the above heading, viz., that Pouncy's process was solely used for large work and enlargements. As a fact, it was used almost exclusively for portraits or views ranging from 5×4 to 12×10, and when I look at a large frame of specimens of my father's early work, done about thirty-eight years ago, I see how favourably they compare with prints that could be made to-day from the same negatives by a process which is considered to give very fine results, platinotype, though I think the dense blacks are rather blacker; and yet, at that day, how few appreciated the work, because they would test everything by the microscopical fineness of a highly glazed albumen print.

Those who are acquainted with, or can refer to, my father's published formula for coating the paper, can see how practically identical it is with those instructions given to "W. Benington" by Mr. Maskell in your pages. I naturally ask, Who is the author?—I am, yours &c.,

Dorchester, March 10, 1896. W. POUNCY.

To the EDITORS.

GENTLEMEN,—I find it hopeless to attempt to persuade "Dogberry" (or, what is perhaps the same thing, Mr. Chapman Jones) to be logical on the subject of the ignorance and false teaching of the text-books relating to carbon printing. The communication of "Dogberry" in your issue of the 6th inst. only the more fully persuades me that I was right in the accusations which I brought, and I cannot help thinking that he has never taken the trouble to examine a print successfully made by the newer process. Had he done so, he could never have written: "It is quite true that the effects sought after by the new school of "pinholists" and "fuzzytypers" may be arrived at by means that would scarcely satisfy the cravings of the majority of photographers, and which would scarcely be expected to do justice to the capabilities of our modern lenses." I have maintained, and maintain, that the new method (and it is distinctly a new method, and not that of Pouncy) can, and will do, justice to these capabilities. As "Dogberry," or Mr. Jones, will not be logical, may I ask them to be practical, and to accept the challenge which I now make; that is, that he, or they, and I, select each one negative, from which they shall make prints by the autotype or any other process? I, on my part, will undertake to produce prints of the same negatives on Artigue paper, which shall be in no way inferior, and shall equal theirs for definition and for "doing justice to the capabilities of our modern lenses." The prints to be exhibited at the next Exhibition of the Royal Photographic Society with the dicta of the text-books, and the upholding thereof by Mr. Chapman Jones written beneath, and also my denunciation of the same. Then, those who run may read, and form their own conclusions.—I am, yours &c., ALFRED MASKELL.

St. James's-street, S.W.

PHOTOGRAPHING IN THE NATIONAL GALLERY.

To the EDITORS.

GENTLEMEN.—The enclosed correspondence may prove interesting enough for publication in your paper.—I am, yours, &c., R. W. CRAIGIE.

Camera Club, Charing Cross-road, March 14, 1896.

[COPY.]

"*Camera Club, Charing Cross-road,*
"*March* 4, 1895.

"THE SECRETARY TO THE TRUSTEES OF THE NATIONAL GALLERY.

"DEAR SIR,—Some two or three years ago I ventured to write to you for permission to photograph in the National Gallery. In reply, you informed me that it was against the rules of the trustees to admit cameras to the gallery, and, in an interview which you were good enough to accord me subsequently, you gave me to understand that exceptions had only been made in favour of a firm of foreign photographers.

"I would like to ask whether the time has not now arrived for the trustees to rescind this rule, which seems, if you will allow me to say so, both unreasonable and arbitrary. On certain days art students are allowed to set up their easels and reproduce the pictures on canvas, &c., and I fail to see why an equal privilege should not be extended to photographers. There are not two opinions as to the rapid strides which photography as an art has made during the last few years, and in no branch of it is there more scope for skilful treatment than in the correct colour-rendering and reproduction of pictures. It was urged as an objection, if I remember rightly, that cameras in the galleries would prove unsightly. Surely, however, by confining the privilege to a certain day or days, and to a limited number of cameras at a time, this objection could be easily met, and, apart from the invaluable assistance that the student in photography would derive from such opportunities, the advantage of being able to procure reproductions of pictures done by some of our most skilled English photographers, such as Mr. F. Hollyer, Mr. A. Burchett, &c., would, I think, be almost universally appreciated. After all, the pictures are the property of the nation, and I cannot believe that, after further consideration, the trustees will any longer be willing to withhold a privilege which would be welcomed by photographers generally, and which would result in a direct benefit to the British public.

"I am, dear sir, yours faithfully,
"R. W. CRAIGIE."

"*National Gallery, March* 5, 1896.

"Sir,—In reference to your letter of yesterday, you are mistaken in supposing that your previous application (made in December, 1891) for permission to photograph pictures in this Collection was refused on the grounds which you mention. The reason assigned was that permission was never given to amateur photographers, and that no exception would be made in your case.

"You are also mistaken in suggesting that permission to photograph here was ever limited to foreign firms.

"The privilege has been accorded to numerous professional photographers, both in London and the provinces.

"It is quite true that the presence of so many cameras in this Gallery has become a source of inconvenience to students of painting and visitors on Thursdays and Fridays. But, if, in addition, amateur photographers were also allowed to practise here, work of any kind, whether in painting or photography itself, would soon become impossible.—Faithfully yours,
"R. W. Craigie, Esq. CHARLES L. EASTLAKE."

[COPY.]

"*Camera Club, March* 13, 1896.

"DEAR SIR,—With reference to your letter of the 5th inst., I am glad to find that I have been wrong in supposing that permission to photograph in the National Gallery was ever limited to foreign photographers, though such an impression seems to have been very general. But why, may I ask, should the privilege be confined to professionals? If there is one branch of photography where amateurs can excel, it is, I think, in the reproduction of pictures, in-

volving, as it does, an immense amount of time and attention, such as the professional is rarely able or willing to afford.

"With regard to the inconvenience to students and visitors, I would merely repeat that, by placing reasonable restrictions upon the number of cameras admitted at a time, risk of this would be either altogether avoided or reduced to a minimum. As a matter of fact, I visited the Galleries yesterday—a students' day—about twelve o'clock, and found but few visitors and not a single photographer. Moreover, the fact of having to procure skilled assistance from outside (where permission is obtained) for unglazing a picture, would, I should say, sufficiently deter all but those amateurs who have a serious purpose in view from availing themselves of the privilege.

"You evidently find yourself unable to hold out any hope that this grievance may be redressed, and, as I have reason to believe that the matter is one of very general interest, I take the liberty of sending this correspondence to the press. "I am, yours faithfully,

"C. L. Eastlake, Esq. R. W. CRAIGIE."

PHOTO-CHROMOSCOPES.

To the EDITORS.

GENTLEMEN,—Mr. Edwards in his former letter (p. 125) made a number of statements which I refrained from commenting upon because I thought that a perfectly just reply would require the use of language that might prove as offensive to him as some of his own remarks did to me. My reply was carefully considered, and intended to be perfectly fair and courteous. I stated only such facts as I found references to prove (references which, I believe, are accessible to Mr. Edwards), confined myself to the main points at issue, and, unlike Mr. Edwards, refrained from personalities. Nevertheless, although Mr. Edwards has not disproved, and cannot disprove, a single statement that I made, he now complains (p. 174) of the "tone" of my letter, and accuses me of "piling up statements on assertions," of "making a wide extension of claims," of a "misstatement of facts," of "misleading statements and random assertions which he [I] cannot prove," &c.

It is evident that Mr. Edwards can in half a dozen words make a misstatement, actual or implied, which I may have to quote whole paragraphs from my patents or other publications to disprove; and, in fact, he has done this so many times already that, in view of the nature of his last communication, I am compelled to ask for space in which to discuss his statements at some length.

"In the first place," Mr. Edwards wants to know how I can reconcile the tone of my last letter with the admission that I did not doubt (his solemn statement) that he conceived the idea of a step photo-chromoscope independently. *Answer:* There is nothing to reconcile. I have said nothing that was inconsistent with a belief in that statement. I have never charged Mr. Edwards with *copying* this or anything else from my patent or other publications. I merely stated that his construction was *in accordance with* my specification, and gave dates of patent application and issue and other publications to prove priority. Mr. Edwards appears to have invented the "copying" fiction for the purpose of creating sympathy for himself at my expense. The fact is that, although my U.S. patent had been published months before Mr. Edwards's first date of record, I accepted his statement that he had a conception of a step photo-chromoscope before he knew of my work; but he did not tell me, and I did not suppose—far less say that I believed—that he had such idea before I applied for a patent on a complete and perfected apparatus, or that he had developed the idea until after my U.S. patent was published. The first date which Mr. Edwards has given, and which rests only upon his own assertion, and evidently refers to the time when he was working upon a three-step instrument (which he showed me when I visited him at his request), is antedated by my application for a patent on a perfected two-step apparatus, with folding chromogram, and everything as now exhibited by me. In that patent, and in my British patent of same date, I claimed important features of the apparatus as since constructed by Mr. Edwards, and other important features which are described in his patent specifications. He cannot therefore manufacture and sell the instrument he has shown without infringing rights which are my own by priority of invention, priority of patent, priority of publication, and priority of public exhibition.

In view of the fact which I have pointed out, and which Mr. Edwards knows perfectly well, that my U.S. patent was *published* months before his first date of record, what does he mean by giving the recent date of publication of my British patent (for the same invention) *as a reason why he could not have copied from me?*

Mr. Edwards makes a grave accusation of "misstatement of facts" with reference to the subject of features claimed in my patent as filed in July 1894, but not shown in his records until December last. The facts are as I have already stated. Mr. Edwards's provisional specification did *not* disclose ideas which I claimed in my patent specifications as new inventions, and for which I claimed, and was granted, protection, and which are shown in Mr. Edwards's drawings, filed for the first time with his complete specification. I shall give references to prove the facts conclusively.

Claim No. 2 of my U.S. specification (published in December 1894, No. 531,040) reads as follows:—

"A photo chromoscope, or photo-chromoscope camera, comprising a casing having a series of seats one above another, for a sectional chromogram, a series of inclined mirrors, some or all of which are transparent, said mirrors being located one behind another in the line of sight, *and inclined in a horizontal plane.*"

Claim No. 3 reads as follows:—

"A photo-chromoscope, comprising a casing having a series of inclined mirrors, some of which are transparent, a series of colour screens, a series of chromogram supports, one above another, *and means for varying the angle of said instrument in respect to the direction of the light rays, substantially as specified.*"

I have italicised the claims to details of the invention, the object and value of which was disclosed in the body of the specification, as follows:—

"The arrangement of images in steps, and the reflection of the light passing through these images by means of transparent mirrors, is not new; but, in the only prior device of this kind with which I am familiar, *the steps were perpendicular to the base of the instrument*, and the transparent mirrors were glasses with parallel surfaces, which doubled the outlines of the respective images. This, taken in connexion with the inconvenience of the instrument, rendered the same so defective as to make it practically useless. . . . In all the various forms of my instrument, however, what may be termed the base edge of the chromogram or of each section of the chromogram is horizontal, and the images are situated one above another, *whereby I am enabled to bring the angles of illumination and vision into the most desirable relation to each other, and to the most convenient source of light, namely, a light sky seen through a window.*"

The significance of these improvements, which I described and showed in my drawings and claimed, and which were recognised as patentable inventions in both the U.S. and the British Patent Offices, may be realised by considering what would be the difficulty of securing proper illumination with my instrument if turned on its side at a suitable angle for convenient vision, and the awkwardness of inserting and registering the folding (or any other) chromogram in that position. The drawing in the British patent of A. H. Cros, No. 9012, May 30, 1889, shows the clumsy appearance and awkward disposition of step instruments as previously conceived.

Now Mr. Edwards's provisional specification does not disclose these improvements, which are first shown by him in his drawings filed in December last, long after drawings of my instrument were published in British photographic journals. Mr. Edwards may or may not have originally conceived the idea of an instrument with horizontal steps and hinged attachment to a baseboard or tray, with means for fixing the angle of inclination; but that construction was patented by me nearly a year and a half before his records show it.

Mr. Edwards does not dispute the fact that I was the first to disclose the idea of using thinly silvered or platinised transparent mirrors in a photo-chromoscope camera (U.S. patent, No. 475,084, May 17, 1892, page 3). Admitting this, he did not need to say more. His reference to "wedge-shaped glass reflectors, chosen at random from a crate of glass," is uncalled for, for more reasons than one, but chiefly because, although I stated that wedge-shaped glass reflectors might be used (an eminent authority, viz., Captain Abney, has praised the ingenuity of the idea), I also described a method *not* requiring wedge-shaped glasses, and, in fact, have not used them in two cameras made last year. Mr. Edwards quotes my statement of the difficulty of obtaining platinised mirrors with plane surfaces as if to my discredit, but he admitted experiencing the same difficulty in his first letter. This difficulty has been overcome, but it was not Mr. Edwards who solved the problem. Transparent silvered mirrors can also be made more perfectly now than when I first took out my first patent; but this, also, by a method which did not originate with Mr. Edwards. In short, the plan of using transparent silvered mirrors in a photo-chromoscope camera was first published in my patents long before Mr. Edwards says he conceived the idea, and such mirrors, quite suitable for the purpose, can now be made by methods which did not originate with Mr. Edwards. In view of these facts, I venture to suggest that the tone of Mr. Edwards's remarks upon this subject is decidedly objectionable.

Mr. Edwards no longer disputes, although he has not expressly acknowledged, my priority in the production of colour records by the simultaneous exposure of three separate and different plates. His claim to this idea may be found in the last paragraph of page 1 of his provisional specification, dated February, 1895; and my publication of the same idea may be found in a lecture published in the *Journal of the Franklin Institute*, Philadelphia, January, 1891, page 15. He also no longer disputes my priority in the idea of composite colour prints, two images of which are on glass, and the third on a thin film between. His claim to this idea may be found in the last paragraph on page 3 of his provisional specification, and my publication of the same idea may be found in my book, *A New Principle in Heliochromy*, published in 1889.

Mr. Edwards challenges me to oppose the sealing of his patent, and intimates that that would be more dignified than prolonging discussion in your JOURNAL. I would remind Mr. Edwards that he is himself entirely responsible for the discussion between us, having commenced it by making false claims to property rights in my inventions, and followed it up by false accusations, misrepresentations, and unkind remarks,

which I was bound to disprove and resent. One can readily understand his reason for wishing the correspondence to terminate with his own letter!

But why is Mr. Edwards so bold in challenging me to oppose the sealing of his patent? and why does he prefer that course for me to discussion in your JOURNAL? I think I can explain the reason very clearly. If anybody copies one of my patent specifications in substance, and my patent drawings in every essential detail, but with the *addition* of some trifling details or modifications (which he may allege to be improvements), and then, if he strictly limits his claims to the inclusion of these details, the Comptroller of Patents, having very limited powers under the Patent Act, might not be able to refuse the patent, whatever opinion he might have formed as to the value of the alleged improvements, and although it would be recognised in law as only an (alleged) "improvement patent," subject to my original claims upon the essential features, and possibly of no legitimate value. Mr. Edwards may have had in mind this possibility of obtaining a patent on technical grounds when he so triumphantly asserted that I would find none of his claims "identical" with my own.

Three more points, briefly: Mr. Edwards proposes, instead of fixing his colour screens for viewing purposes upon the instrument itself, to fix them upon the chromogram sections, so that a complete set of colour screens will be required for every complete colour record, instead of one set for any number of colour records. At first glance this idea might appear stupid (no one would for a moment think of calling it an improvement); but, after what has passed between us, would I not be justified in entertaining a suspicion that it had been done in view of my patent rights with the deliberate intention of getting around my claims by appearing to leave out of his construction one of the elements which he supposed was claimed as an essential part of my invention, and then to make a virtue of what he conceived to be a necessity for him, and pretend that he thought this plan was an improvement? It should be known, then, that before my patent was issued, in 1894, I called my patent attorney's attention to the possibility of somebody attempting to evade my claims by such a trick, and he told me that such construction would at least amount to "contributory infringement," since the instrument would not be operative until the colour screens were brought into position and performed their function as indicated in my patent; but, as a further safeguard against "misunderstandings," *we made one of the claims complete without reference to the colour screens.* Perhaps Mr. Edwards has overlooked this fact. I will also inform him that I have French and Austrian patents, dated some months before his first date of record, in which I expressly stated that, although it was *best* to have the colour screens fixed to the photo-chromoscope, they *could* be fixed to the chromograms! Second, Mr. Edwards also shows a plan for using the instrument for projection purposes with three sources of light. It can be shown that this device with *three* sources of light cannot be made to give a larger or brighter image on the screen than my own special triple lantern attachment will with *one* source of light! Third, the above are, I think, fair illustrations of the true inwardness of Mr. Edwards's alleged improvements. For the purposes for which he commends his alterations in detail and application, they appear to me to be positively retrograde movements. Nevertheless, in so far as they appear to show "new matter," they may possibly give him a technical right to the nominal acquirement of a useless patent.

Mr. Edwards has made it necessary for me to go somewhat into details in this letter, although I think it should be sufficient for the public to know that the invention was patented by me before Mr. Edwards's date of record, that my British patent dates with my original application, that Mr. Edwards has no standing, except possibly technically, as to modifications and details, which are not improvements, and which he has nothing of his own to apply them to; that, despite all this, he appears to threaten to manufacture and sell the apparatus, and to involve me in legal expenses to protect what I have earned by honest labour, and protected by performing every legal obligation; and that he is paving the way for such an act by making false accusations, and indulging in personalities calculated to prejudice the public against me and my inventions.—I am, yours, &c.,

F. E. IVES.

MR. W. H. HARRISON.

To the EDITORS.

SIR,—I should like to be allowed to add my word to the appeal already made by Mr. Pringle and Mr. Varley on behalf of our friend, Mr. W. H. Harrison, so as, perhaps, to bring the matter under the attention of some of his friends or acquaintances who may not yet have heard of his affliction and circumstances.

Mr. Harrison was always ready with personal assistance, and with useful suggestions and advice by which many photographers have benefited without knowing the source of the service.

In my own organizing work at the Camera Club this was the case, and I am very anxious to add my tribute of respect and esteem for his thoughtful consideration, his services to photography, directly and in his outside journalistic work, and his modest way of giving a helping hand.

I sincerely hope that a sufficient number of friends will rally round to give him some substantial assistance.

Mr. F. H. Varley is kindly undertaking the management of the appeal, and contributions should be sent to him at 82, Newington Green-road, N.—I am, yours, &c.,

GEORGE DAVISON.

Camera Club, March 14, 1896.

Answers to Correspondents.

*** *All matters intended for the text portion of this* JOURNAL, *including queries, must be addressed to* "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 2, *York-street, Covent Garden, London. Inattention to this ensures delay.*

*** *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

*** *Communications relating to Advertisements and general business affairs should be addressed to Messrs.* HENRY GREENWOOD & CO., 2, *York-street, Covent Garden, London.*

PHOTOGRAPHS REGISTERED:—

J. L. Hopper, 4, Pendle-street, Nelson, Lancashire.—*Photograph of railway accident at Nelson on February* 18, 1896.

Mr. Philip Newman, 91, King's-road, Brighton.—*Photograph of an amended reproduction of original equestrian photograph of H.R.H. the Prince of Wales.*

Mr. J. Kennerell, 7, York-row, Wisbech.—*Photograph of an illuminated address to the Hon. Arthur G. Brand; photograph of solid silver presentation plate to the Hon. Arthur G. Brand.*

Mr. Wm. Wilkinson, High Causeway, Whittlesea.—*Photograph of sketch in "Illustrated London News" of July* 10, 1847, *of the entry of General Sir Henry Smith into Whittlesea after the Battle of Aliwal.*

RECEIVED:—R. W. PAUL, BIRMINGHAM PHOTOGRAPHIC COMPANY, ALFRED WATKINS, and others. In our next.

THE NEW PHOTOGRAPHY.—COLONEL. Thanks for the cutting. Similar experiments have already been noticed.

BLISTERS.—CARBOLIC. We have no recollection of having given such a preventive. Kindly let us know the page, we can then supply the information desired, no doubt.

BLEACHING.—BOTHERED. The bleached image will not alter if it is kept in the dark. If the latter cannot be done, why not bleach with bichloride of mercury, which is not alterable by light?

CARBON TISSUE, &c.—CAPE COLONY. The Autotype Company, 74, New Oxford-street, and Elliott & Son, Barnet, supply materials for carbon printing. We are not aware of the existence of any "monopoly."

GELATINO-CHLORIDE — COLLODIO-CHLORIDE. — INVESTIGATOR. 1. If the firm has not replied to your complaint, we certainly can do nothing in the matter. The paper has a good reputation for keeping. If it is yellow, there is no remedy. 2. Collodio-chloride prints are seldom enamelled; when they are, they are done in the same way as albumenised-paper prints are—with collodion and gelatine.

MEALY PAINTS.—B. LIVERMORE complains of mealy prints, and, in his letter, incidentally mentions that the toning bath was the "usual acetate bath," used within a few minutes of mixing. Here, at once, is the source of the trouble. The acetate toning bath should be made up at least twenty-four hours before it is used. Some workers never employ this toning bath until it has stood two or three days after it is mixed.

WOODBURY LANTERN SLIDES.—SLIDE asks "what presses are necessary in printing lantern slides, as he would like to try his hand at the process?"—No press is required for the printing. The cleaned glass is simply pressed on the metal mould, after the ink is poured on, for a few seconds, and then left till the ink has set firmly. The only press required is an hydraulic press for making the metal moulds from the gelatine reliefs.

SULPHUR TONING, DISSOLVING GOLD.—J. H. J. asks: "Will you kindly give us (1) the formulæ of sulphur toning as recommended by Dr. Thresh in his lecture before the Leeds Camera Club? (2) By what means can we dissolve the gold that adheres to the sides of the stock gold solution bottles?"—1. We do not know; the formula was not given in the report supplied to us. 2. One part of nitric acid to four or five parts of hydrochloric acid will dissolve the gold off as a chloride.

MOUNTANT.—T. C. SHORTER. Flour paste is scarcely to be recommended as a photographic mountant. Starch is better, but it should be freshly made. Nothing, however, beats gelatine for mounting silver prints.

CERAMICS.—TRYING says: "In the JOURNAL for February 28, you mention Messrs. Ethelbert Henry and H. Snowden Ward's book on ceramics. I would thank you very much if you would please give me the full address of Messrs. Dawbarn & Ward."—In reply: The address is Farringdon-avenue, E.C.

FAULTY LENS.—If the surface of the glass has become dull and iridescent, the instrument should be returned to the maker. Clearly an unstable glass has been used for one of the elements. It is impossible to say how long a lens should last. Some of the earliest lenses made are still as good as they ever were, so far as the glass is concerned.

COLOURING P. O. P. IN OILS.—E. W. P. There is no book published on colouring P. O. P. prints in oil or in water colours, but the treatment any other photographs receive will answer as well with the P. O. P. paper. If you are ignorant as to colouring photographs, we should advise you to get a few practical lessons in the work from a practised hand.

EMPLOYMENT IN CANADA.—F. PERCY says: "Can you give me any information concerning the prospects of photographers and photographic assistants, salaries, &c., in Canada? Also will you oblige by informing me where I can obtain a copy of the American professional paper?"—In reply: 1. From inquiries we learn that photographic assistants have no better prospects in Canada than here at home. 2. There are several photographic papers published in America; which one do you mean?

LENS COMPETITION.—COLONEL says: "In a paragraph in last week but one's JOURNAL I saw it stated that Messrs. Voigtlander & Son had recently offered three lenses of the value of 20*l.*, 15*l.*, and 10*l.* for the best pictures taken with lenses of their make, reserving the right to reproduce the successful pictures on terms to be arranged. If the notification appeared in the JOURNAL, I never saw it, and I presume it is now too late to compete?"—Yes, too late to compete. The competition closed on March 1.

ARTIFICIAL LIGHT.—W. E. K. says: "I would be very much obliged if you could give me any information as to any artificial light I could use for photographing at night. I have to 'take' a group of an amateur operatic society on the stage, with scenery, &c., and it is impossible to get the company together at any other time."—In reply: We should recommend our correspondent to employ, say, four flash lamps, each charged with about a drachm of magnesium. An exposure of three or four seconds at *f*-8 with a fairly rapid plate should suffice.

COPYRIGHT.—F. J. ROBINSON says: "Having recently photographed a popular minister in this locality entirely at my own expense, I should be obliged if you will kindly inform me how to protect myself by registering same, cost, and how long the copyright remains in force. Must each position be registered separately?"—In reply: Send our publishers two unmounted copies and one mounted copy (together with 1*s.* 7*d.*) of each photograph you want registered, and they will do what is required. Copyright lasts for seven years after your death. Better register each position.

SELLING AN INVENTION.—H. PRADEAN says: "I have lately invented and provisionally protected a hand camera. As I am unable to put it on the market, I should like to sell the invention. If you would kindly give me information how to proceed and where to apply, I should feel greatly obliged. As I have never put such things on the market, I am afraid I should find it rather difficult."—In reply: Your best plan will be either to advertise the invention for sale, or submit to some of the apparatus-manufacturing houses whose announcements will be found in our outer columns.

LANTERN-SLIDE DEVELOPER.—A. F. P. writes as follows: "I have lately been making some lantern slides by the wet-plate process, using the following developer:—Pyro, 12 grains; acetic acid, 1 ounce; water, 12 ounces. 35-grain silver bath, acidified with acetic acid. The results were good, the tone partaking of a deep-claret colour. In reading the article on *Wet Plates*, in the current Annual, I find the iron developer alone given. Is this considered superior to pyro? and, if so, will you kindly say why, as I have never been able to get such good results with it for transparency work, either as to colour or fineness of grain, as with pyro?"—Our correspondent is quite right, that the colour with pyro developer is warmer, and the grain finer, than is the case with iron; but greater skill is required with the former developer to get the best results than with the latter. It is for this reason that the iron developer is almost universally used for lantern slides.

DEVELOPING.—A. C. ANSED says: "I get my living by taking views round about the country, and up to the present have been buying my developer ready-made. A friend of mine, however, obliged me with the prescription, and to save expense I thought I would make my own developer. Can you oblige by telling me, through your paper, what is wrong? The developer does not answer at all, and will not bring the picture out. Would caustic soda answer instead of carbonate of soda? I don't want to waste the developer on hand if I can help it?"—The developer you have made up ought to work all right, possibly you have not allowed time enough. You can substitute caustic soda for the carbonate, but only use the same weight of that as of the hydroquinone. Possibly hydroquinone is not well suited to the plates you are using. Why not use the developer recommended by the makers of the plates? Dozens of formulæ for developers are given in the ALMANAC.

STUDIO.—SIDE LIGHT says: "I should be very glad of your opinion. I am building a studio, where there is plenty of room for one, 30×15, with north light, but I shall be overshadowed by a tall building about thirty feet away. Under these conditions I am undecided as to two points—measurement of side light from floor to eaves, and how low to glaze side light. A reply to these two points will greatly oblige."—If the buildings are as shown in the sketch, the high building will not practically interfere with the light. About eight feet from floor to eaves will do. The glass need not be nearer the floor than two feet six inches.

RÖNTGEN PHOTOGRAPHY.—MR. E. SCAMELL writes: "I notice in your last issue, under the heading 'EX Cathedrâ,' you think there is an opening for a professional to take up the new photography (Röntgen process). I have pleasure to inform you that I have now had the necessary apparatus (large induction coil, &c.) on order for some weeks, and am daily expecting the delivery of same. As soon as it comes to hand, I hope to be able to fill the want, at any rate, amongst local medical men, some of whom have already been to me, thinking perhaps I could do such work."—We are glad to have our correspondent's letter. See also the first page of this number of the JOURNAL.

THE COOKE LENS.—C. H. CHAVANT, of Greenville, Jersey City, N.J., says: "I read in your BRITISH JOURNAL PHOTOGRAPHIC ALMANAC, on page 829, your article on the Cooke lens. I feel very interested in the description of this lens, and would like to know, if such a lens is for sale, by whom it is made, and where. I have looked over all the advertisements of the ALMANAC, but could not find anywhere the advertisement of the makers; therefore I take the liberty to write you directly, asking you to have the kindness to let me know the name and address of the manufacturers of the Cooke lens."—In reply: The makers of the Cooke lens are Messrs. Taylor, Taylor, & Hobson, Slate-street Works, Leicester.

STUDIO FOR PORTRAITURE.—A. S. (Frome) writes: "I want to build a studio, and should be very grateful if you can assist me with some few particulars. 1. What is a suitable size for ordinary portraiture—length, width, and height of sides? 2. What extent of glass is necessary? and, 3. Is it sufficient if only one of the sides is glazed, and one side of the roof, or is it best to have both sides glazed?"—1. About thirty feet by fifteen is a convenient size for portraiture. From floor to eaves about eight feet. 2. Five or six feet at each end; top and sides opaque; the rest of glass. If both sides are glazed, ten feet at the camera end may be opaque. 3. This much depends upon the aspect of the studio.

PHOTOGRAPHING A CEREMONY.—R. & Co. write as follows: "A foundation-stone is to be laid in this town next week by the Mayor. We have applied for permission to photograph the ceremony, and have been refused, the reason being that another photographer has arranged to do the work. We shall, however, be able to get a very good photograph from outside the enclosure. What we wish to know is this, supposing the appointed photographer succeeds in registering the copyright in his picture before we do ours, can he prevent us from publishing ours, and, if we are first, can we prevent him from publishing his?"—Certainly not; neither can prevent the other from publishing his work, no matter which is registered first.

RÖNTGEN PHOTOGRAPHY.—W. H. H. says: "It has occurred to me very often since the advent of the new photography or X rays that, were it possible in surgical cases to produce the bones white instead of the shadowgraph form, it would, doubtless, be an immense advantage. With that end in view I have been experimenting a little. I enclose a print of one of my first efforts. Should like your opinion. Not having the necessary apparatus by me to make the shadowgraphs, I have had to confine myself to book illustrations, which make it more difficult to get good results from. All the work I have seen done by the X rays is of the shadowgraph form, hence my sending you this."—In reply: Medical men tell us there is no advantage in what you suggest.

TONING COLLODIO-CHLORIDE PAPER.—C. G. & Co. write: "We are using, as a printing paper, the collodio-chloride paper; and, as we find we get the best results with the combined toning and fixing bath, we would ask you whether we might consider the prints to be as permanent as those toned and fixed in the separate bath. We have heard different opinions of this, and shall be glad if you could kindly oblige us in this matter."—We do not recommend the combined toning and fixing bath any more for this paper than we do for any other. What has been said against the combined bath for gelatino-chloride paper applies equally as well to the collodio-chloride. Any desired tone may be obtained on collodio-chloride paper with separate toning and fixing, if the paper be good.

STUDIO LENS: PRINTS.—SUBSCRIBER (Swansea) writes: "Will you kindly answer the following:—1. What would be the best colour to paint inside studio which is matchboarded, and built on H. P. Robinson's plan? I am now troubled with double lights in the eyes; how can I prevent it? The side wall of the studio is yellow. 2. What is the use of the extra hood or tube supplied with a Dallmeyer triplet? 3. Can the freshness of a gelatino-chloride print when wet be retained when dry or mounted? My prints turn a yellowish colour. If they should be rewetted, they turn again to the fresh colour."—In reply: 1. Any neutral or unobtrusive tint will answer—say a dark French grey. The double light in the eyes is due to the faulty lighting of the sitter. 2. We do not know what you mean by *extra* hood. Possibly it was supplied for some special purpose of the purchaser. 3. The gloss can be retained by squeegeeing the prints on glass and mounting them while in contact with it. If the prints turn yellow when dry, there has been something wrong in the manipulation.

THE BRITISH JOURNAL OF PHOTOGRAPHY.

No. 1873. Vol. XLIII.—MARCH 27, 1896.

Contents.

EX CATHEDRÂ.

A fortnight ago we gave publicity to a letter from Mr. R. Bennett, of 19, Brunswick-street, Liverpool, in which that gentleman expressed a wish to acquire photographs of ancient wind and flour mills, for the purpose of illustrating a book on the subject. In reference to the matter, we have received from Mr. Frank M Sutcliffe, of Whitby, a letter in which he makes the following comments:—

"I doubt if you would have tried to help him (Mr. Bennett) if you had known that he only offers 2*s.* 6*d.* for right of reproduction. I have told him that we photographers are not allowed to charge *less* than 10*s.* 6*d.* according to the rules of our Copyright Association."

* * *

Two shillings and sixpence, even with the additional advantage of the insertion of the artist's name under the reproduction, which Mr. Bennett tenders, for the right of using a tolerably scarce or, indeed, any photograph, is certainly, in all conscience, a small enough fee to offer. We should image that Mr. Bennett was not aware of the existence of the Photographic Copyright Union, and of its strenuous efforts to persuade photographers not to continue in the fatal practice, once common with so many of them, of undervaluing the products of their time, labour, and money. But, indeed, whether this be so or not, we repeat that 2*s.* 6d. is a very small sum to offer, and one which we should imagine even the verlest amateur would not accept.

* * *

As we have previously announced, there will be delivered, under the auspices of the Affiliation of Photographic Societies, six experimentally illustrated lectures upon the subject of photography with the bichromate salts, at the rooms of the Royal Photographic Society, 12, Hanover-square, W., on Fridays, April 10, 17, 24, May 1 and 8, and on Tuesday, April 28. The following is the syllabus:—April 10, *Scientific and Historical Preliminary*, by Captain W. de W. Abney, C.B., D.C.L., F.R.S. 17, *Carbon Printing*, by Mr. J. A. Sinclair. 24, *Collotype*, by Mr. W. E. Debenham. 28, *Woodburytype*, by Mr. J. D. Geddes. May 1, *Photo-lithography and Photo-zincography*, by Mr. W. T. Wilkinson. 8, *Process Work Applications*, by Mr. W. T. Wilkinson. Admission is to members of affiliated societies by tickets, to be obtained beforehand from the Hon. Secretaries of their societies, 1*s.* the six letures; non-members, by tickets, obtainable only on application to Mr. R. Child Bayley, 12, Hanover-square, W., 3*s.* 6*d.* the six lectures.

* * *

Yet another professional photographer is taking advantage of the opportunities offered by the publication of Röntgen's experiments for increasing the scope of his business. Mr. E. Senior, of 219, Camberwell New-road, writes: "Referring to your first paragraph of March 13, *re* the 'New Photography,' I beg to say I have been carefully studying the subject from the first, and am fitting up, at above address, the most approved apparatus for the production of Röntgen photographs, and I hope, in the course of a few days, to be in a position to undertake this new class of scientific photography. The appliances, which are of the latest description, will be further added to as fresh developments may seem desirable."

* * *

"Photo," under which *nom-de-guerre* a country photographer conceals his proper name, writes: "I beg to call your attention to the enclosed cutting from this week's *Answers*, thinking

that, if inserted in the JOURNAL, it would be interesting to see what the various opinions of correspondents would be respecting the absurd statement."

* * *

THE cutting from our interesting contemporary implies that some photographer (unknown) derives a considerable revenue from exhibiting the photographs of his sitters in his window. "'Would you be surprised to hear that many of my customers pay me to put their photographs in my window?' asked a photographer of the writer. 'It's a fact, I assure you; and, what is more, it is nearly always they who make the request, not I who make the offer. They generally ask me after a sitting what the cost of the photographs will be, and when I tell them they say, "How reasonable! And what would be your charge for putting one in a nice frame in your window?" What *do* I charge? Half-a-guinea for a *carte*, a guinea for a cabinet, and so on, for each month. Nearly all the photographs you see in the window—and there are some sixty or seventy—are paid for in that way; indeed, I make a clear 150*l*. a year by exhibiting photographs in the window. Then, there is another important aspect to the matter. Some of my customers, after they have sounded me as to whether I will exhibit their photographs or not, will sit again and again, and have dozens of likenesses of themselves in different positions before they are contented that they have one sufficiently complimentary to merit being exhibited. All this means money to me."

* * *

MANY of our professional readers who are continually on the look out for fresh ways of improving business will, doubtless, thank us for pointing out to them such a simple plan of increasing their turn over! A guinea for the exhibition of a cabinet photograph for one month must be very remunerative. We fear, however, that the whole paragraph is more remarkable for the evidences of a fanciful imagination it displays than for any relationship, however remote, to solid fact. Photographers, in our experience, rarely, if ever, earn money so easily; nor are sitters, however vain, so ready to throw their money away.

* * *

SOME months ago we published several letters relating to the plan of issuing cheap enlargements, adopted by *Pearson's Weekly*, in return for one or two coupons and a payment of five or six shillings. A correspondent, Mr. Wilson, of the Wilson Art Studio, Southsea, draws our attention to the circumstance that the plan is still favoured by our contemporary. He says: "They state that when they made this same offer some months since they received 7000 photographs to enlarge. Just imagine what 7000 enlargements (which ought to have been done by the legitimate photographer) would mean to our trade! May I through our esteemed trade medium, THE BRITISH JOURNAL OF PHOTOGRAPHY, appeal to every one of my fellow-photographers and all connected with the photographic trade in this country to show them (*Pearson's Weekly*) how unfair it is to enter into competition with their customers?"

* * *

WE are happy to afford our correspondent the opportunity of airing his grievance against *Pearson's Weekly*, although we expect, from the result of the former agitation on the same subject that appeared in our pages, that no direct practical good will result. There is one source of consolation always at hand when photographers are confronted by competition of this character, and that is, that the man who produces really good work will not, as a rule, find his business affected by the coupon systems of disseminating three-quarter life-size enlargements at 6*s*. 3*d*. each, notwithstanding that, as stated in Mr. Pearson's offer, "these pictures, if ordered through artists, would cost you from three to five guineas."

THE RIGHT TO THE NEGATIVE.

THIS question is continually being brought before the Courts, though one would have thought, from the many decisions that have been given upon it, the point was settled long ago. Not so, however, for, on Tuesday last week, Mr. Edwards, of Peckham, was sued in the Lambeth County Court for damages for the detention of eighteen photographic negatives of certain monumental works. The negatives, it seems, were taken in the ordinary course of business, and the plaintiffs, a firm of monumental masons, claimed them as their property. During the hearing of the case one or two points of interest worth noting were raised. For the defendant it was contended that the negatives, under the Copyright Act, were his property. Judge Emden said, as a matter of law, that was so. The other side argued that, as the negatives were taken as a matter of business, they were included in the charges. But the Judge said there is a decisive case on this very matter, and he well remembered it, as he was counsel in the case, and by the decision the photographer was held to be the owner of the negative. Plaintiffs' counsel contended that the question at issue was not one of law but of fact, and put in invoices, charging the plaintiffs for "taking negatives and supplying copies of photographs," &c., as supporting his view that the negatives were taken for the plaintiffs. The Judge, however, said that there was no evidence that there was a special contract, or that the negatives were specially paid for, adding that, if the plaintiffs' solicitor's contention was right, a person sitting for photographs should be entitled to claim the negative. In the end judgment was for Mr. Edwards with costs. On the question of an appeal the Judge advised that the plaintiffs should take time to consider the matter, and remarked that, "when the public want negatives, they should take care to establish a special contract."

There is not much difference between this and other suits that have been taken into Court, except one point which it is well to make a note of, as it still further strengthens the photographer's property in the negative. It is this: In this case the invoices were worded in this way, "taking negatives and supplying copies," &c. Now, we have more than once strongly recommended photographers to make no mention of negatives in making their charges, as it might be construed as a special charge for them by the Court in some instances. In the present case it clearly was not. However, we still advise that no allusion be made to the negative, or the taking of it, in invoices, as in future cases the Judge that is called upon to adjudicate may not be so well versed in the custom of the photographic profession as is Judge Emden.

Röntgen's Work in High Quarters.—It is stated that the German Emperor is indebted to the use of a Röntgen photograph for a knowledge of the true condition of the bones of his arm, that have brought about the well-known imperfection that he suffers under.

New Reagent for Bromine and Iodine.—Mr. J. H. Kastle, in the *American Chemical Journal*, states that dichlorobenzenesulphonamide liberates bromine and iodine from metallic bromides and iodides, and can be used either in the solid state or in carbon bisulphide solution. It may be used instead of chlorine water, but, like this, excess must be avoided, otherwise iodine tetrachloride will be formed. It is possible to recognise the presence of iodine in solutions containing ·0000127 and ·00000635 grain, together with ·04 and ·00036 grain bromine respectively.

Chloride of Silver and Hypo.—In 1894 Valenta argued that the formula for the mutual action of these two substances as usually given —$3Na_2S_2O_3+2AgCl=(Ag_2Na_4.3(S_2O_3)+2NaCl$ — was not correct, but Ernst Cowen qualifies this declaration. If the silver chloride is not present in excess, he holds the equation to correctly state the phenomena; but, if the chloride be in excess, a less soluble salt—$(AgS_2O_3Na)_2$—is formed. He thus verifies the results postulated thirty years ago by MM. Davanne and Girard in their classical researches on the causes of fading of silver prints.

Italian Naval Nomenclature.—One of the earliest items of intelligence from Rome, after the receipt of the disastrous news from Abyssinia, was to the effect that the warships *Bromida* and *Plata* were about to be dispatched to Africa with reinforcements. This looks as if the Italian Government are making a new departure in the naming of their men-of-war, and if, having started with the two most important constituents of the modern dry plate, bromine or bromide and silver, they follow on with gelatine, collodion, pyro, ammonia, hypo, &c., or their Italian equivalents, their fleet will look almost as formidable on paper as on the sea.

Death of a Renowned Portraitist.—The death of Mr. George Richmond, R.A., is announced as having occurred on Thursday, last week. He was born in 1809, hence he had attained a good old age. During his long lifetime he produced between two and three thousand portraits, many of which have been engraved. The deceased artist was identified more especially with a particular style of work known as the Richmond head. This style of work has been largely imitated in photographic enlargements, and one well-known firm of photographers in London, a few years ago, made a special feature of "Richmond heads," in which they did a considerable business.

The National Portrait Gallery.—At last there is some prospect of this Gallery being open to the public in the near future. In reply to a question put in the House of Commons one day last week, Mr. Balfour said that he understood the Trustees proposed to open the Gallery on April 4, "provided the appointments in the staff of curators, resident officers, and police are sufficiently advanced to enable them to do to. Therefore there is some doubt about the date but the Curator hopes it may not be very long after that time." One would have thought—at least, any one with business ideas—that, in an affair of this kind, the appointment of the staff would not be left till everything else was completed, and then be made, if necessary, a reason for a delay in the opening. Alas, for Government "red tape!"

Artistic Posters.—An Exhibition of Posters is now open at the Royal Aquarium. It is one that we imagine the photographer will take but little interest in. To him the poster, however artistic it may be, is a nuisance of the first degree. How often is what would otherwise have been an artistic "snap-shot" picture completely spoilt by some obnoxious advertisement. Again, how often has the photographer to forego an interesting landscape, unless he is content to include advertisements of quack nostrums, soap, foods, &c.! Painters are agitating for the abolition of this class of advertisement, and all credit to them; but they are, after all, in a better position than photographers, as they can omit them from their works, but photographers perforce have to include them if they take the picture at all.

Telescopes for Photography.—The supposed expense of suitable instruments has had a deterrent effect on some who would like to utilise their small telescopic possessions in photographic directions; but, as has already been shown, work of high value can be carried out with no more costly instrument than an ordinary magic-lantern lens, and in the *Astronomical Journal* is a paper by Professor Schaeberle on the relative value for the purpose of reflecting and refracting telescopes, the latter when of large proportions being, as is well known, of immense cost. He gives it as his opinion that photographs of planets taken by an instrument of the former class with a focus of from twelve to fifteen feet will be equally good as those taken with the most powerful of the expensive type.

Edison and Röntgen Rays.—A paragraph has been going the rounds of the papers, to the effect that Mr. Edison has been experimenting with an immense number of bodies in regard to their possible fluorescing power under Röntgen rays—over 1800 has been named, but the chemical chosen is said to be shrouded in mystery. Be that as it may, Mr. Edison, according to a paragraph in last week's *Nature*, has telegraphed to Lord Kelvin, in the following words: "Just found calcium tungstate, properly crystallised, gives splendid fluorescence with Röntgen rays, far exceeding platinocyanide, rendering photographs unnecessary." As there is no reason to doubt the genuineness of this telegram, it is evident that, if the luminosity is so great as is suggested, the tungstate will form a new weapon for the surgeon far exceeding in practical importance the photographic results of the new discovery.

Are Röntgen's Rays of Cathodic or Anodic Origin?—A new reply to this already confusing problem is already given by Mr. H. Espin. He has been making a considerable number of experiments to determine the question by placing Röntgen opaque screens in various positions with regard to the Crookes' tube. He had, with others, been struck with the fact that he sometimes obtained double images, as though two radiant points were connected with the issue of the rays. He placed thick sheets of metal at right angles to the dry plate; he used also a series of short lengths of brass tubes. He summarises his results and conclusions in a letter in the *English Mechanic*, last week, as follows: "The explanation of these results is simply this; that besides the cathode rays there are as well anode rays," and he gives a diagram explaining how the multiplication of the shadows is brought about under this assumption.

Respirability of Acetylene.—It has been stated that the respiration of air impregnated with small quantities of acetylene was inimical to health: but, from experiments made upon dogs by Nestor Gréhaut, Marcellin Berthelot, and Henri Moissan, it would appear to be much less poisonous than ordinary coal gas. A mixture of coal gas, air, and oxygen, containing twenty per cent. of the latter, was nearly fatal to a dog after ten minutes breathing it; but twenty volumes of acetylene, 20·8 of oxgen, and 59·2 of nitrogen, produced no visible effects after a respiration, though, when the acetylene was increased to forty volumes, the dog died in less than an hour. Berthelot, in experiments made some years ago, found that a few per cents. per volume of acetylene present in air had no injurious effect. It is clear, therefore, that no trouble need be apprehended from an occasional slight leakage of acetylene in the air of a living room.

Further Surgical Results.—Mr. A. F. Stanley Kent, of St. Thomas's Hospital, is credited with being the first to photograph the bones of the entire human trunk. His sciographs show those portions of the body lying between the fifth rib and the pelvis. The space occupied by the kidneys is rather denser than the surrounding tissues. Then also Mr. J. Macintyre, writing from Glasgow to *Nature*, states that he has used a cryptoscope, and "been able to look straight through a skull, in which I had placed two or three bullets, and I had no difficulty whatever in seeing shadows of them, although somewhat enlarged." He has photographed the inner table of the cranium, the upper part of the spine in the neck, and half the spine

and vertebræ of an adult. It is rather difficult to understand the meaning of the quoted portion of his letter, seeing that the "inner table" is the inner of the three layers of bone of which the skull bone is composed.

The Metric System in America.—It is stated that a Committee of Congress has under consideration a Bill to render metric weights and measures compulsory in all official transactions, and it is reported that the majority of its members are in favour of its becoming law at an early date. It is proposed to make the system compulsory in all Government Departments on July 1 next year, and, after July 1, 1899, it is to be the only legal system of weights and measures recognised in the United States. It is surmised, if the system is mandatory in all Government Departments, that the example would be quickly followed in all private contracts. At present England and America are about the only countries that have held aloof from the metric system. At various times attempts have been made to introduce the metric system in photography in this country in place of the present grains, drachms, and ounces, but to no purpose. All Continental formulæ are given in the metric system, and most know the trouble some have in accurately translating them into our grains and ounces.

An Acetylene Lamp.—The *Scientific American* has recently given an illustrated description of a new lamp designed by the well-known French scientist M. Trouvé, for burning the new illuminant somewhat upon the style of a paraffin or petroleum lamp. The gas is produced in a manner similar to that already designed for acetylene generators. An outer glass vessel contains a smaller one of the same material, which contains a metal cage for the calcium carbide in layers separated from one another by discs of glass, to keep the production of gas under control. One difficulty in designing a lamp consists in the condensation of moisture in the tubes leading to the burner. This he has done by using two concentric tubes connecting with the top; at first the gas passes through both to the burner; then, when the water begins to condense in the inner tube, it seals it and acts as a siphon, the gas continuing to pass to the burner through the outer tube and the siphon action going on the whole of the time. Further initial condensation is brought about by a large plate of iron attached to the inner tube. The average consumption of this new lamp is about 3¼ ounces of carbide for thirty-eight candle hours.

Light Storage.—This topic, once the subject of intense interest and heated discussion in photographic circles, referred to what might be termed invisible light, but at the meeting of the Paris Academy of Sciences, held last week, M. Henry described experiments on light storage when the illumination was to be visible as well. After trying phosphorescent tablets of zinc sulphide rendered luminous by ten minutes' exposure, he subjected them to various influences with the idea of arresting, yet not destroying, the light-emissive process. Experimenting with electro-magnets and various coloured glasses, also the compression of the sulphide of 100 kilogrammes to the centimetre, he obtained little or no result, but, struck by the effects of addition of heat in increasing the light emission and of obstruction in destroying it, he was seized with the idea of trying extremely how temperatures and the results were a complete success. He plunged a luminous tube in a freezing mixture, at a temperature of 79° C. The luminosity was entirely destroyed, and, upon withdrawing the tube, there was no light visible, but, as soon as its temperature arrived at that of the atmosphere, the sulphide once more began to glow. This is, after all, a matter of theoretic interest only, for, as M. Trouvé points out, it is only in polar regions where you can get cold without labour.

Weather Forecasting.—Three weeks ago, it will be remembered, we gave Mr. Clements' weather predictions for the current month, so that our readers could judge for themselves as to their correctness. Last week the annual report of the Meteorological Council to the Royal Society was issued as a Blue-book of the smaller type. The United Kingdom is studded all over with stations, from which observations are being constantly received at head-quarters. These centres extend from Jersey and the Scilly Isles to the Shetlands. In addition to these there are some thirty or more Continental stations. From the reports received from the centres forecasts are issued three times a day, and are for the next twenty-four hours, dating from the time being. It is claimed for the forecasts issued in the evening that fifty-six per cent. of them proved correct, while twenty-seven were partially correct. We are told that "partial" implies "more than half." For the forecasts in reference to the hay harvest, when, by the way, the weather is generally pretty settled, it is claimed that sixty-one per cent. of them were successful. However, the Board of Agriculture, after an extended trial of these forecasts, have since dropped them.

It would be a little interesting to know how many photographers rely upon the weather forecasts for the day when they have any important work on hand. It would also be interesting to know how the words "perhaps," "possibly," "probably," &c., count in compiling the complete and partial successes in the forecasting as given in the report. Some people think that, for the fifteen thousand pounds or upwards granted yearly to the Meteorological Department, we should have more accurate forecasting than we get, considering that it is only for the ensuing twenty-four hours.

Photographing at the National Gallery.—The correspondence, published in our last issue, between Mr. Craigie and the Secretary to the Trustees of the National Gallery, seems, at first sight, a little hard on amateur photographers. But, after all, it is not so bad as it appears. Professional photographers are, without restriction to nationality, allowed to photograph the pictures, under certain conditions, before ten o'clock in the morning, and on students' days; but, if an art student requires any particular picture, he or she has the preference over the photographer, and the latter must put off his work till the former has done with the picture — sometimes a question of weeks. As a rule, the painter student can work from the picture *in situ*, whereas the photographer must have it removed, and unglazed, with, of course, a certain amount of risk to the painting. Further, the Trustees know that, when permission is accorded to a professional, the reproductions will be disseminated far and wide, to the benefit of art students generally, while those of the amateur will be confined to his own folio, or perhaps those of a few friends. Therefore, it is not so very unreasonable that the Trustees will not allow the public to be incommoded by cameras even on students' days, for the individual amusement of their owners. The sentence in Mr. Craigie's letter, "If there is one branch of photography where amateurs can excel, it is, I think, in the reproduction of pictures, involving, as it does, an immense amount of time and attention, such as the professional is rarely able or willing to afford," will take many by surprise, if not cause amusement. No professional would think, for a moment, of applying for permission to photograph in the Gallery without being prepared to give the necessary "time and attention" to the work, as well as the skill and experience requisite to secure the best results. Without these he would know that the copies would have no sale and the venture would be his loss. Where is the amateur that can excel the published photographs of the pictures in the National Gallery?

Very Juvenile Photography.—We often hear of the practical interest taken in photography in our public schools, and we occasionally see a youngster, scarcely in his teens, enthusiastically amusing himself and his schoolfellows with a photographic apparatus, possibly a present from some kind old "Uncle Jack." When we do, we look upon the juvenile as an embryo photographer of the right type. Last week our amateur contemporary chronicles (?) juvenile photography in the older days, which quite eclipses anything in modern times. It says: "At the third meeting of the Photographic Society, held on April 7, 1853, Mr. Samuel Fry exhibited what he regarded as the first photographic camera made in this country, an instrument made for him in 1839 by Mr. Edward

Palmer, of Newgate-street," &c. The late Mr. Samuel Fry died in 1890, aged fifty-six. Consequently, in 1839, when the camera was said by our contemporary to have been made for him, he was but five years old. This quite "beats the record" in photographic infant prodigies. When chronological events are recorded, they should be accurate, otherwise they are misleading, and as such may possibly be perpetuated by the rising generation of photographers if they remain uncorrected. As a matter of fact, the camera alluded to was shown by Mr. Peter W. Fry, no relation whatever to the late Mr. Samuel Fry.

Mr. P. W. Fry was one of the first, the very first, workers of photography in this country, and an ardent experimentalist of the old school. He was contemporaneous with F. Scott Archer in the invention of the collodion process. Writing in 1852, Hunt (third edition) says: "The successful application of a solution of gun-cotton in ether to form the film for receiving the sensitive surface on glass appears to belong to Mr. Fry and Mr. Archer. There is some difficulty in fixing precisely this point, since the dates of actual publication are very uncertain." This Mr. Fry was one of the founders of the Photographic Society of London—now the Royal Photographic Society—and served as a member of its Council for years. It may be mentioned that the first President of the Society was Sir Charles Eastlake, then President of the Royal Academy. At that period artists did not treat photography with the contempt that some affect to do now.

Glass Cells for Orthochromatic Purposes.—Several correspondents have called attention to the method of building up glass cells for the coloured solutions employed, to wit, of the blue and violet rays referred to by Mr. F. H. Burton in a previous issue, pointing out that the process is far from being so easy and simple as that gentleman would seem to wish to convey, while the result is scarcely to be relied upon to stand much rough usage, or even the ordinary wear and tear of studio work. No mention is made of grinding the edges of the glass plates forming the sides of the cell, which would be absolutely necessary if they were built up in the manner suggested; and, even when this was done, the cemented edges would be extremely liable to separation on the slightest jar. A far better way, it is claimed, and we think with justice, would be to place the strips of celluloid—or, better still, of glass of definite thickness—*between* the edges of the side and squares, when they would not only have a firmer hold, but would be protected by the sides from any chance knocks.

But we would suggest an even simpler plan, which we can answer for from past experience as being quite efficient. It is due, if we remember rightly, to the ingenuity of the late Mr. Walter B. Woodbury, and was, we believe, first described in a little pamphlet, *Science at Home*, published by the Sciopticon Company as a means of improvising a trough or cell for exhibiting chemical and other experiments with liquids in the lantern. The basis of the cell consisted of a wooden frame similar to, but rather thicker than, an ordinary lantern-carrier, and having a circular opening about two and three-quarters of an inch in diameter, or any smaller size. The top side of the carrier is open in the centre, and into this well are dropped or pushed two ordinary lantern slides of plain glass, separated by a piece of indiarubber tubing bent into U shape, and of such thickness that, when the plates are pushed home, the tube is squeezed tightly between them, forming a waterproof trough open at the top. For orthochromatic purposes several modifications will suggest themselves, but the principle remains, and we can speak as to its efficacy. This little device was exhibited at the Photographic Club some years ago by the late Mr. George Smith of the Sciopticon Company.

JOTTINGS.

I should like briefly to endorse the appeal that has been published on behalf of poor W. H. Harrison. Of all the appeals that have recently been made, this is surely the most deserving, for what could be more tragic than the fate of being suddenly reduced to impotence and helplessness in the prime of one's life and intellect? Harrison's work in photographic journalism has extended over a period of nearly thirty years. He was a cultivated writer, and a man of well-grounded practical and theoretical knowledge. Moreover, it must not be forgotten that to him the world is indebted for the first published suggestion for the emulsification of the silver haloids in gelatine. His literary work was by no means confined to photography, although it was in connexion with the latter that he was best known. I hope that a liberal response will be made to the appeal. The Hon. Treasurer is Mr. F. H. Varley, 82, Newington Green-road, N.

A friend is kind enough to forward me a couple of newspaper extracts, which I append in parallel columns. They relate to the Röntgen rays, or "new" photography, of which they take views that it would be hard to find in greater contrast or more diametrically opposed to each other. Röntgen's lucky accident has been one of the most fortunate finds that medical and surgical science, and consequently human pain and suffering, have had for years, and yet the *Pall Mall* young man is "sick of the Röntgen rays," and would like to "execute all the discoverers;" and so on, through a series of pitiful puerilities which are supposed to pass as smart writing. Mr. Astor's paper evidently wants some new and common-sense contributors, as well as a new editor. Contrast the *Pall Mall's* exhibition of ignorance and stupidity with the weighty and sensible observations of the *British Medical Journal* on the same subject. That contrast, as my friend remarks, is striking, and it will grow all the more striking as time goes on.

Pall Mall Gazette—

"We are sick of the Röntgen rays. It is now said, we hope untruly, that Mr. Edison has discovered a substance—tungstate of calcium is its repulsive name—which is potential, whatever that means, to the said rays. The consequence of which appears to be that you can see other people's bones with the naked eye, and also see through eight inches of solid wood. On the revolting indecency of this there is no need to dwell. But what we seriously put before the attention of the Government is that the moment tungstate of calcium comes into anything like general use it will call for legislative restriction of the severest kind. . . . . Perhaps the best thing would be for all civilised nations to combine: to burn all works on the Röntgen rays, to execute all the discoverers, and to corner all the tungstate in the world and whelm it in the middle of the Atlantic. Let the cetacea contemplate each other's bones if they like, but not us."

British Medical Journal—

"In spite of the attention which has from the first been given to the subject of the new photography, it seems difficult to get the general public to take a rational view of what the new process can and cannot achieve. We are in great danger of an anti-climax, during which the pendulum of public opinion will swing back and demolish the solid structure of practical utility which the science of skiagraphy has already built up. Wild talk about photographing the interior of the brain, the processes of digestion and respiration, &c., can only lead to unreasonable disappointment. . . . . We must therefore wait patiently till those engaged in investigating the discovery have provided the means for such work, and avoid the sad results of over-estimating a discovery which, relegated to its proper position, will be of the greatest benefit to surgery and mankind at large."

I am informed by a member of the Royal Photographic Society, who, however, seldom attends any of its gatherings, or takes any more active part in its affairs than the regular payment of his subscription, that the last meeting of the Society's Council was enlivened by the performance of a screaming farce. Mr. H. P. Robinson was proposed for election as an Honorary Fellow—and was not elected. Matters of this kind are, I should have thought, best not made public; but, evidently, some members of the Council think otherwise, for the news, figuratively speaking, is all over the place. Perhaps, though, this is scarcely to be wondered at, for nothing could be more laughable or absurd, or difficult to treat seriously, than the proposal to make Robinson an Honorary Fellow of the Royal Photographic Society—except, possibly, Robinson's acceptance of the compliment if

it were conferred upon him. And now, to carry on the sequence of topsy-turveydom, I am wondering if we shall hear of some waggish Salonite proposing *me* for membership of the Linked Ring?

The Photographers' Benevolent Association is dead—with three hundred pounds in the bank, or rather, under the control of the Registrar of Friendly Societies, who appears laudably anxious to give his consent to the money being handed over to some suitable body who will disburse it in a charitable or benevolent manner. At present no body or society has been discovered who can, will, or is able, to step temporarily into the discarded shoes of the P. B. A. and get rid of the money. The bitter irony of the position is that there is plenty of call for it. I myself, within the past few weeks or so, have been the recipient of no less than four letters from needy photographers seeking help, whose cases were just those that the Benevolent might have been glad to deal with. But not one of the four—no, not one—had ever subscribed a single penny to the funds of the P. B. A., or had stirred so much as a finger to keep it alive.

What with the Röntgen rays, kinetoscopy on the screen, and the stereo-photo-chromoscope, the various photographic societies have found, during the winter that is leaving us, plenty to talk about and discuss; all three subjects, indeed, have given quite a new impetus to photography. The fact that a number of professional photographers have laid themselves out to take radiographs for surgical purposes is quite a consolation to me, who, at the risk of being called hard names, have so often, in this column, scolded the fraternity for its callous and conservative indifference to new ideas. Animated photographs on the screen, moreover, is a field the outside boundaries of which have only just been touched, while, as I gather from Mr. F. E. Ives and Mr. Edwards that stereo-photo-chromoscopic cameras for securing photo-stereographs in colours are likely to be marketable articles, amateur photography should also find, in the near future, new scope and new pleasures; and not before it wanted both.

COSMOS.

CARBON PRINTS WITHOUT TRANSFER.

THE subject of carbon printing without transfer has been on the *tapis* for some time, and there seems to be no reason to doubt that for some purpose, and under certain conditions, it is quite feasible. I am not going to argue the point as to whether the text-books have been all along wrong in teaching that development from the back of the exposed tissue is an absolute essential to success; on the contrary, it is my intention to suggest an application of what I may deem the method of printing which I have little doubt may be worked out to an advantageous issue. I have seen many examples of carbon printing by the direct method produced both anterior and subsequent to the advent of Swan's process, by Blair, Pouncy, and others, but I scarcely think that any unbiassed judge would hold them to be equal in technical excellence to the best or even to the ordinary run of transfer prints. The prominent features of all such pictures that have come under my notice have been want of delicacy in the finer details, and heaviness and want of transparency in the shadows.

I have not had the good fortune to be able to examine any of the more modern examples of this class of work, but I can see no reason why what was impossible two or three decades ago should suddenly become easy at the present day; although I am willing to admit that, with the more modern methods described by Mr. Alfred Maskell and M. Demachy, perhaps better results are obtainable than was formerly the case; their acceptance is probably as much due to a certain change in popular taste as to any very marked improvement in quality. The increased popularity of matt-surface effects on rough and smooth paper has, no doubt, done much to pave the way for a class of pictures that would scarcely have secured favourable notice in the days when albumen prints were the standard of excellence.

But, turning to the technical side of the question, I scarcely think that Mr. Alfred Maskell's description of the kind of film required correctly explains the rationale of the process or its possibility. He says: "The object to be aimed at is a deposit of colour held in suspension in just sufficient of the gum so that each grain of colour is separate, as it were, from its neighbour, and not one on top of another." Practically this is an impossibility; but, even accepting such an ideal film, the production of gradation in any form from a negative in natural half-tone is an obvious impossibility, for wherever the light acted, whether in the deepest shadows or in the most delicate gradations of the high lights, the effect would be the same. There would be no depth of colour to give force to the shadows, while in the lights each individual particle must either be rendered insoluble or else be left in a condition to be washed away on development; in the one case the lights would have the same depth as the shadows, in the other they would be perfectly bare.

Undoubtedly the possibility of the process depends upon, in the first place, the extreme tenuity of the sensitive film and the exquisite fineness of division of the colouring matter; but beyond this we require some explanation of how or why in the half-tones and finer gradations the action of the light is not as great as in the shadows. Remember, we are supposed to be working with a film composed of a single layer of particles of colour of practically equal size—or it may even be of a multiple layer of particles infinitely small. In the first case any action of the light, whether in the shadows or half-tones, must render insoluble the whole thickness of the layer; or, in the second case, the surface of the layer is rendered insoluble, and the underlying particles confined, which amounts to the same thing. This is, in fact, the old text-book teaching of the principle of the process.

But the supporters of the new method refer to a certain granularity of the film as being necessary, not only for the due penetration of the light, but also for successful development, and there can be little doubt but that it is to the partial granularity, combined with extreme tenuity of film and fineness of division of the colouring matter, that the production of an image in half-tone is due in the first instance. But an equally important point in the argument will be found, I think, in the choice of the vehicle or binding material in which the colouring matter is held, and it will be noticed that both Mr. Maskell and M. Demachy employ pigmented gum. I do not mean to infer that the employment of gelatine would render the process unworkable; on the contrary, the very practical method of Mr. W. H. Sherman referred to in these pages a few weeks back is based upon the use of gelatine—but I think gelatine would render the task more difficult by reason of its giving a more homogeneous film or one in which it would be more difficult to secure the necessary degree of porosity or granularity.

Besides this, the solubility of gum in cold water is another point in favour of ease of development, the higher temperature necessary for the solution of the unacted-upon gelatine would have a tendency to loosen and wash up the isolated portions forming the shadows and half-tones of the picture. With gum, on the contrary, the chief portion of the development could be performed with cold water and very slightly tepid or a lukewarm temperature resorted to to clear the half-tones. Here is where I fancy the whole possibility of the process rests. We know, in printing the ordinary carbon tissue, it may be quite insoluble in water of a certain temperature; but, if a greater heat be applied, the half-tones may be lightened without materially affecting the more powerfully impressed portions. In the case of the direct printing method, it is the application of a moderate temperature that softens and dissolves the underlying particles of colouring matter and gum without so acting upon the indurated surface layer, and this, by virtue of its porosity or granularity, allows the dissolved portions to escape through the interstices. Gelatine, by reason of its greater continuity or homogeneity of film, would be more likely to retard, or altogether arrest, the escape of the soluble colouring matter, as, in fact, it does in the ordinary process.

A word or two on the subject of the production of the granular or porous film. Here, again, I think gum especially, and albumen in a less degree, will be found to favour an open film on account of their semi-crystalline character when in the dry state, but that openness will be still further increased by the presence of crystalline potassium bichromate. All carbon printers are aware of the necessity of keeping down the proportion of the bichromate to gelatine in order to prevent crystallisation of the salt on drying, and it is one of the

points in favour of the sodium salt that a larger quantity can be used without introducing this trouble. But the tendency to crystallisation is much greater in the case of gum than with gelatine, and partakes of a different character, being finer in form, and, in fact, always present more or less, though it may not show on the surface, however small a proportion of the chromium salt may be used.

Thus, whereas, in a film of gelatine carrying a moderate proportion of bichromate, the cohesiveness of the vehicle masks or altogether prevents crystallisation, in the case of gum, and to a less degree with albumen, on drying, the semi-crystalline film breaks up into innumerable minute particles of pigmented gum separated by equally minute crystals of potassium bichromate. On exposure to light, the former are, on the surface at least, rendered insoluble where the separating crystals are left soluble, and on development are washed out and form the interstices or channels through which the under layer of soluble matter is washed out of the half-tones. The crystalline or granular character of the film will be found to be greater if the bichromate is mixed with the pigmented gum before coating than when it is applied afterwards in solution, and the degree of granularity can be varied within very wide bounds by altering the quantity of salt used, as well as by mixing the ammonium and sodium salts with bichromate of potash.

From experiments I have recently made in the direction of Artigue prints, I believe that a method on somewhat similar lines will be found useful in photo-etching and engraving, as it forms a "resist" which, while offering a certain amount of grain, adheres far more firmly to the copper or zinc plate during the process of "biting." For this purpose, however, gelatine would seem to be preferable to gum, or, at any rate, a certain proportion of it seems to give a stronger film, and the fact of its being applied in solution to the freshly cleaned or grained metal plate goes farther to ensure its more perfect adhesion than would be the case with mere squeegeeing.

In conclusion, let me say that, while, under the conditions given above, I fully believe in the possibility of successfully rendering half-tone without transfer, I am still of opinion that the text-books are strictly correct in their teaching, that the perfection of gradation is only possible by one or other of the transfer methods.

W. B. Bolton.

INSIDE SOME LONDON STUDIOS.

No. I.—Mr. Thomas Fall's.

Probably among his brother professionals no photographer is better known or more respected than Mr. Thomas Fall, of Baker-street. On a recent visit to that well-known studio we found Mr. Fall engaged in his favourite occupation of answering letters from photographers in various parts of the country who were seeking his advice on points of practice, charges to sitters, studio construction, and other matters, in all of which Mr. Fall's long experience is invaluable. Then we were interrupted by a sitter, whom Mr. Fall, with characteristic adroitness, instantly put into a good humour with a racy anecdote or two, and we had leisure to wander about the reception-room, admiring the specimens, which include carbon and platinum prints of great beauty, as well as albumen prints, to which process Mr. Fall, in common with many other workers, is inclined to revert.

Taking leave of the reception and dressing-rooms, which are marked by quiet taste and homelike attractiveness, we proceed to explore the studios, of which, at Baker-street, there are two. The principal one is the larger, and most of the work is done in it, although occasionally the smaller one is utilised. The dimensions of the studio are: Length, about 30 feet; height at apex, 14 feet; width, 18 feet; height to north aspect eave, 8 feet; to south, 7 feet. Ground glass is used for glazing purposes, the north light being controlled by spring blinds of greenish-blue fabric. The accessories have been selected with an eye to naturalness of effect in the resulting photographs, and they include a few upon which dogs can be posed, for, as our readers may be aware, Mr. Fall (himself a great dog-lover) devotes much attention to this kind of work.

Dependent from the roof, and sliding in a groove at the apex, where it is controlled by a ball-and-socket movement, is a kind of large portable tunnel, consisting of a metal frame covered with baize. This is suspended over the camera, and may be easily moved to and from the sitter. Mr. Fall terms it a luxury, and says he finds it especially useful in preventing the accretion of atmospheric fog between the sitter and the lens.

The studio on the south side is likewise glazed at the angle of the roof, spring blinds being also available; and, as we notice this fact, Mr. Fall takes occasion to put us in possession of his views with regard to the use of reflectors for lighting the shadow side of the face. Directing a small boy to be seated, he asks us to judge of the relative effects of lighting the shadow side of his face with a reflector, and by means of direct light controlled by blinds. In the one, Mr. Fall points out, the cross light is made disagreeably conspicuous in the eyes of the sitter, while, by judicious use of direct light, this is avoided, and generally a softer effect of lighting is obtained. Another point upon which he is emphatic is the mistake of having an excessive height of studio, the effect of which is to concentrate too much top light on the sitter.

Mr. Fall's admiration of retouching is limited. Indeed, when it is carried beyond what he considers it to be its legitimate sphere, viz., the removal or softening down of defects, he becomes an opponent of it. Pressed as to whether lady sitters are not responsible for the abuse of retouching, he dryly informs us that the men, and old men at that—including artists—are generally as bad as the ladies in this respect, and sometimes worse.

Naturally, we engage Mr. Fall to talk to us about dogs, on which, photographically and generically, he is an authority. Everybody is familiar with Fall's dog photographs, and it is safe to say that, in the domain of canine portraiture, he is not beaten. But we are as much impressed with the following sentiments on the subject of dog photography as with the actual photographs. "This," says Mr. Fall, "is the age of the dog. The regard in which he is held was never greater. The affection bestowed on dogs is only inferior to that with which children are looked upon. Ladies in particular, who have no children, find their best substitutes in dogs. Drawings, paintings, and photographs of dogs are, consequently, thought more highly of than ever they were, and the photographing of dogs is daily becoming more and more lucrative than the photographing of their owners. But, of course, as you say," concludes Mr. Fall, "it is not easy work at the first go off. You must know your dog—and it's a good many years since I took my first dog photograph."

Many a time in these pages, of recent years, have we and others discussed the question whether albumen printing has received its death-blow. Mr. Fall admiringly hands us a batch of exquisite albumen prints, and utters the formula we have heard issue from so many photographers' lips, "Nothing like a good albumen print after all." "But give me the paper of thirty to forty years ago," he continues, "and I will ask for no other." Remarking on the absence of the electric light installations from all his establishments (for Mr. Fall has branch studios in Finchley-road and Bayswater), our host appeared to think that "the electric light for portraiture" might be useful as an advertisement, but that, practically, it is not much availed of.

The honourable place Mr. Fall has won in the profession is the result of hard, good, and persistent work. He is sixty-three years old, and has been in business for himself about half that time. Many of his assistants have been with him over twenty years, than which he requires no other testimonial as an employer. He is, as we have already hinted, the kindly willing adviser of large numbers of his brethren all over the country; a warm supporter of any movement started for the advancement of photography; but, with native bluntness, gives it as his opinion that a professional photographer cannot make constant attendance at society meetings compatible with commercial success.

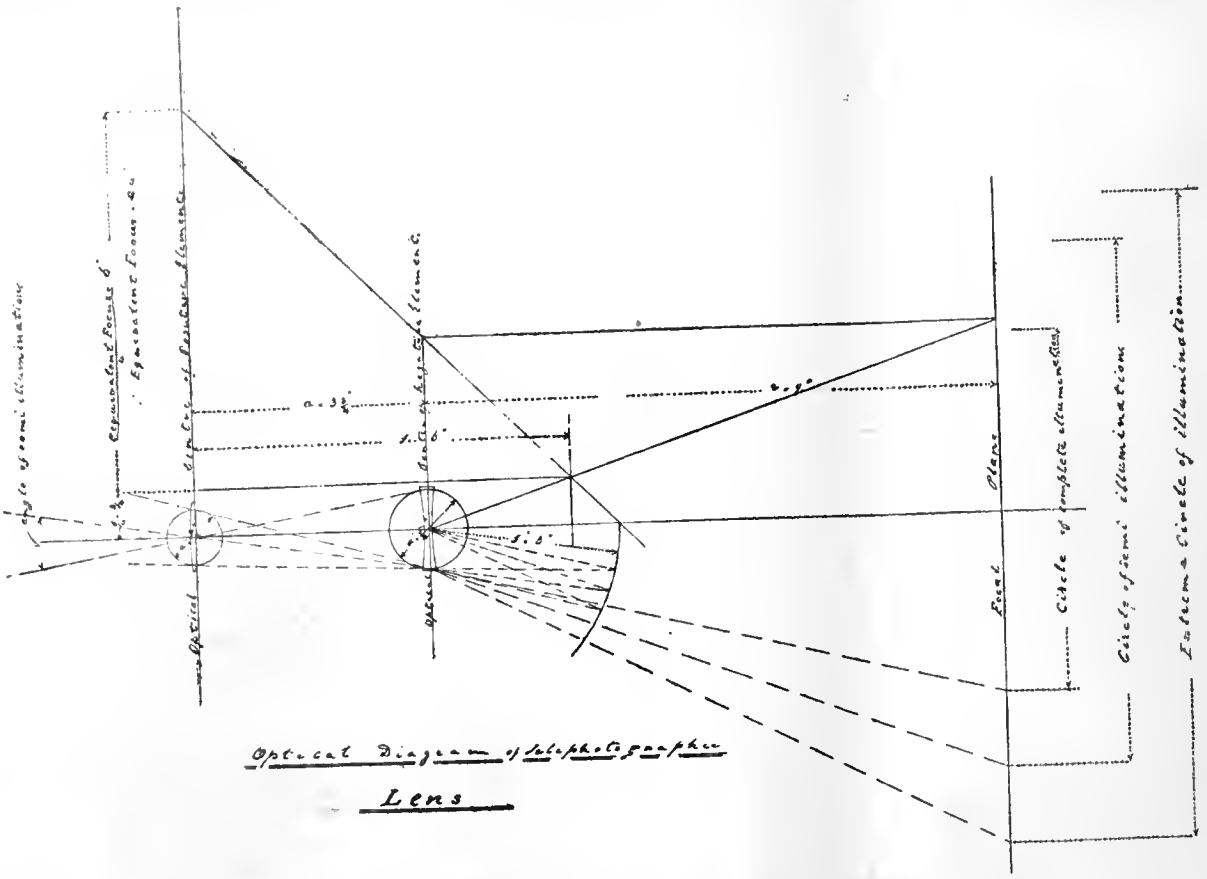
TELE-PHOTOGRAPHIC LENSES BY GRAPHIC CONSTRUCTION.

Mr. Charles Louis Hett writes: "In your issue of August 4, 1893, you published a very useful diagram on the above subject by

Mr. Hancock, of Cardiff. The assistance which I have derived from this diagrsm has induced me to extend it so as to show at a glance the whole effect of any tele-photographic combination.

"I enclose an example which I think may prove of interest to many of your readers. In order to facilitate comparison, I have employed the same data as those which were used by Mr. Dallmeyer (THE BRITISH JOURNAL OF PHOTOGRAPHY, July 28, 1893), and adopted by Mr. Hancock in constructing his diagram.

"It will be observed that I have used one-quarter of the equivalent and negative foci in the vertical component of the construction. This is simply a matter of convenience. Were the full foci used, an acute-angled triangle would result, and consequently greater liability to slight error."



COPYING.

[London and Provincial Photographic Association.]

In the first place, for copying, you must have a camera and lens, and these should be chosen with regard to the class of work to be done. If money is no object, then get the best of both sorts; but, if it is, then, if the subjects to be copied are photographs or pictures where a slight falling off in definition does not matter, a good rapid rectilinear lens will answer the purpose But, if you want to copy line work or fine dotted engravings, the definition must be of the best, and therefore the cheapest lens in the long run will be one of the newer forms which are free from astigmatism, for, if a rapid rectilinear lens be used for that purpose on a somewhat dull day, you have to use such a small stop that you cannot see to focus, and therefore your focus is but guesswork, and, if a moderately large stop is used, the negative seems to show signs of vibration, the lines one way being sharp, and those at right angles being blurred. The lens also should not be of the shortest possible focus, as, when copying the same size or larger, the camera will be so close as to throw a shade across part of the picture, though, for copying very large pictures to a very small size, it may be of advantage to have a short-focus lens, as it may save getting the subject too far from the source of light when copying in an ordinary room, or save getting too far away from the subject when the atmosphere is hazy, which might flatten the resultant negative.

A heavy camera has a great advantage over a light one, and should have the back focussing adjustment, as that saves a great amount of time in adjusting and focussing, and is easier working, as you will frequently have the camera at its full extension; but the front focussing camera can be used; but, when copying near the same size or larger, the body of the camera must be shifted each time the lens is, otherwise it is easily seen that, as there is but one point of focus, and that may give too small an image, if the lens is racked forward, the size of the image will increase, but definition is lost, and can be regained by sliding the camera bodily backwards. If the camera is a light one—and most of the front focus ones are, I think—it will be advisable either to weight it, or have some arrangement by which it can be clamped. Mr. E. J. Wall recommends a camera fixed to a board, which slides in grooves, while the board, to which he fixes his picture, moves all ways to enable him to centre it properly.

A cheap and convenient stand I have had made consists of a four-legged table stand, five feet six inches long, fourteen inches wide, and three feet nine inches high, at one end of which is a board, fixed by means of two irons attached to the legs of the table by thumbscrews, which allow of the board being taken away when a picture of too large a size has to be copied, when, by means of small wheels on those same two front legs, it is easily moved to a central position opposite a large board fixed to the wall. These boards are marked with a series of horizontal lines, and the height of the lens marked, at which diagonal lines mark the centre. By means of these lines I fix my picture square if it is a flat print, but when it is in a book I fix the book as near as possible to guess central; but sometimes that is impossible, as when a small picture is somewhere out of the centre of a large sheet, and then it is sometimes handy to be able to shift the camera to one side or the other of the stand, so that, in my opinion, the sliding fixture is in some cases a delusion and a snare, as it is perfectly easy to see that the camera is square on the stand. It is also handy to put it out of square when copying photographs which are slightly out of rectilinearity, as the distortion may then be overcome; but, if there is much distortion, it is useless to try to rectify it. When your picture is fixed, you slide the camera into position and focus; then, with a heavy camera, no further fixing is requisite; but, of course, you want to be gentle with it in putting in the slide, which shouldn't bite too tight in the rebates. It will be advisable to always clamp the camera if you are working near a thoroughfare where there is a lot of heavy traffic, as it is surprising what an amount of vibration you can get.

Now, as to fixing the picture to the board, if it is a flat print, all that has to be done is to fix it with drawing pins at the corners, not by sticking the pins through the paper, but at the side, so as to allow the head to hold the edge of the paper. Sometimes it is convenient to just catch the smallest possible edge, and then the pin should be put in slanting, the point away from the picture. In the case of an unmounted

print—albumen especially—this is frequently necessary, and also to have a large number of pins, as it is better to do without a cover glass if possible on account of reflections, but if you cannot keep the print flat by those means a cover glass must be resorted to; then put your black focussing cloth round the lens so as to cover all the bright metal and polished wood. This hint also applies to framed and glazed pictures. If the picture has been crumpled, it will greatly improve it to iron it, face down, with an ordinary flat iron, and then leave it in a somewhat damp place for a hour or so.

If the picture is in a book, I usually put two strings round as much of the book as is behind the picture and round the board, one at the top and one at the bottom, and draw them as tight as I safely can; then, if the leaves bulge unevenly, I put two thin, narrow strips of tough wood under the strings, which keeps them flat, and then, if the binding holds the lower end more forward than the top, I slip two wedges down, one each side, until the picture is upright. If the book is thin and of very large surface, so as to reach beyond the sides of my board, I have four strong laths, which I use instead of the string, and, with one at the back of the board and the other in front of the book, fix the two ends with strong rubber bands; in this case, as a rule, the binding is not in the way.

If the picture is on tracing or other semi-transparent paper, it will give a clearer and brighter negative if a piece of white paper is put at the back.

Now, as to exposure, it is not always advisable to take the well-meant tips which you have given gratis on this point, as, if you are copying black and white, you will be told that the shorter the exposure the stronger the contrast, and, when you say that the negatives still develop soft and flat, you are told to still halve the exposure. Now, my experience is that a black-and-white negative should develop with pyro and soda in from ten to fifteen minutes, according to temperature, and that, if they do not develop in that time, they will be flat through under-exposure; and also, that, if they develop much quicker, they will be flat from over-exposure; and it is a very difficult thing to judge by the resultant negatives whether they are under or over-exposed. Therefore, always time development, and judge by that. I also find that, with the plates I use, the maximum density, without choking the lines, is obtained in four times the time that it takes to get the whole outline just visible.

Here I should like to mention that there are degrees of black and white. Blacks may range from the pale blue-black with many rotten or half-covered places, or the faded, rusty black of old books to the intense black of modern engravings, and white range from the faded yellow of some old books, and the yellowish cream papers to the pure white of some of the new engravings. It is obvious that the same class of negative cannot be got from a rusty black on faded yellow as can be got from an intense black-and-white engraving; but it may surprise some that the very white-and-black print will stand more exposure than either of the others, and the rotten blue-black on cream the least of all. But it is from the fact that the intense black will take longer to reflect any appreciable amount of light than the faded ink, while the blue-black, being a more actinic colour and thin, will stand but very small amount of exposure, though, at the same time, the whites are in inverse ratio; therefore, taking exposure, the ink will stand as two to one, and the reflecting power of the whites as two to one, there will be a difference of four to one in the resultant negatives. That is an extreme case, but such can easily be found. In the case of the faded print, a clean but thin negative can be obtained, and is sufficient for some purposes, but for others must be intensified, while a rotten print will never copy well, as every thinness in the ink is exaggerated. So always expose for the longest time that the blacks will stand without developing up, and that is the point where you will get the strongest contrast; with less, the whites take so long to come up that the blacks fog; with more, the blacks will develop before the whites have gained sufficient density, and, as before mentioned, will both be flat.

In copying a photograph two or three times, the black-and-white exposure should usually be given according to the density of the photograph to be copied and the class of negative required. In extreme cases of flatness or a mere ghost of an image, the brightest effect will be obtained by exposing the same time as for a black-and-white, while very hard and solarised P.O.P. prints will want four times that exposure. I should always advise correcting errors as much as possible in exposure, as it is easier and more certain, and, in case of more being required, it can be done in development without much loss of time, whereas it, at best, can only be done with great waste of time in development alone. Another reason is, that, if you alter gradations in exposure, you can develop two very different negatives in the same dish, side by side, and get what you want. Don't get your negatives too dense, or your image will show all the marks of the paper copied. I find that a good time for developing photo-copy negatives is three times the time of the first appearance of the whole outline, in all usually six to ten minutes.

There are other methods of copying, as, when we want a negative from a negative, or lantern slides from the original negative, the only extra apparatus is for the front of the camera, and that may consist of condenser, artificial light, and holder for negative or transparency; or, for daylight, a multum-in-parvo class of apparatus, which is bulky, or a simple stand with grooved runners, which raise or lower at will by means of thumbscrews, which will hold any size from quarter-plate to 12 × 10, the intervening space being covered with a black focussing cloth; and, as it is inconvenient to work with the apparatus pointing to the sky; a reflector (white paper will do) is placed at the back at an angle to throw the most light into the lens; out of doors that will be 45°, but elsewhere other considerations come in and alter the angle. For making a negative from a negative, a transparency must be made; this can be done either by contact or in the camera. From a contact transparency the negative must be made in the camera, and from a camera-made transparency the negative may be made by contact, the best method being, perhaps, a contact carbon transparency, as that process gives a softness and range of gradation very difficult to equal by any other process, besides being cheap. It is a process that no amateur need be afraid of, and certainly no professional photographer ought to be without.

I am getting frightened at the length of this short paper, so will finally conclude by saying that I have never known a negative to fog by exposure to light after it is once put in the fixing bath, though some (so it seems to me) think that the slightest gleam of light on the last atom of visible bromide of silver has fogged it. I never knew light action to show (short of days' exposure) unless developed. H. C. Rapson.

WATKINS' DEVELOPING COMPETITION.

[Notes by J. Sterry.]

The conditions imposed—first, corresponding high lights to be equal in density; and, second, unexposed strips to show either no fog or equal fog—entailed considerable labour, and perhaps was one cause of there being so few competitors, and that only four out of seventeen could show decided change of gradation.

In ordinary work neither of the conditions would be binding, but whilst the second in the present case was necessary, because one object was to determine if any connexion existed between fog and varied gradation, the first was not so, and, moreover, prevented the full variation from being demonstrated. Thus, supposing that it was found that sixteen times as much exposure was required to be given with developer *A*, as with developer *B*, equal density should not be found upon any equal exposures, but where they varied as one to sixteen.

It may be said perhaps the results would be the same, but that is not so, because, in order to fulfil the conditions of equal densities at some one equal exposure only, it was necessary to develop so as to make the density curves cross at that point, instead of being parallel, and this unequal development told very unfavourably in all the prints. (If competitors had only been required to show a crossing point, and not necessarily make it the highest light, much trouble would have been saved, and several would not have been disqualified.)

An examination of the negatives gives far more information than can be obtained from the prints, because differences due to unequal development can be separated from those due to the composition of the developer.

But few of the plates are available for photometric measurement; only four competitors made use of exposures with definite ratios which could be compared, and two of these, 44 and 45, show but little variation.

Mr. Watkins having been good enough to send me the negatives, the measurements of 250 and 54 are given below, as they together show the effects obtained, from extreme under to extreme over-exposure.

Exposure Ratio.	250 *A* Density	250 *A* Diff.	250 *A* Opacity Ratio	250 *B* Density	250 *B* Diff.	250 *B* Opacity Ratio	54 *A* Density	54 *A* Diff.	54 *A* Opacity Ratio	54 *B* Density	54 *B* Diff.	54 *B* Opacity Ratio
1	·31			·08			1·02			2·15		
2	·60	·29	1·95	·10	·02	1·05	—*	·43	2·69	—	·04	1·1
4	·89	·29	1·95	·16	·06	1·15	1·45			2·19		
8	1·18	·24	1·74	·33	·17	1·48	—	·38	2·40	—	·03	1·07
16	1·42	·19	1·55	·60	·27	1·86	1·83			2·22		
32	1·61	·08	1·20	·99	·39	2·45	—	·38	2·40	—	·05	1·12
64	1·69	·12	1·32	1·47	·48	3·02	2·21			2·27		
128	1·81			1·99	·52	3·31	—			—		
	Correct Exposure 1 to 8. Over-exposure 8 to 128.			Under-exposed 1 to 32. Nearly correct 32 to 128.			Nearly correct throughout 1 to 64.			Greatly over-exposed throughout 1 to 64.		

Approximately the following differences in exposure would give the best results, although the prints do not indicate nearly so much.

249, 250, 251 and 6 ..... One to sixteen.
246 ..... One to seven
54 ..... One to thirty-two.

230 being landscape, difficult to measure, but probably at least one to ten.

The most important point of all clearly brought out is, that the *best results are given by normal development.* This is well seen in 250 (as pointed out by Mr. Cowan). 250 *A*, having a long range of correct gradation, whilst 250 *B* has none at all, though coming somewhere near in the high densities. All the examples measured confirm this point also, and indicate that, when a plate will allow of a developer being used without bromide at all, the best possible results may be expected (see THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC, 1894 p. 776, *Selective Developers*).

For both 54 and 6, only sufficient bromide (½ grain) was used, to secure compliance with the condition respecting equal fog, also that it might be shown that alteration in gradation is not dependent upon the use of a restrainer, yet it is seen from 250 that time is saved, by a large amount of bromide permitting the alkali to be increased.

Notwithstanding that the competition has not secured all that might have been expected, and can hardly be satisfactory to Mr. Watkins, it has not been altogether without use, in showing that definite alteration by varied development is not quite so easy, nor so useful, as generally supposed.

Will it be necessary to wait for another competition and prizes before anything more can be done? No light whatever has been thrown on tentative development.

THE KINEOPTICON.

MR. BERT ACRES, who, as our readers are aware, has recently demonstrated his kinetic lantern before several of the photographic societies, and may claim to have been first in the field with a public exhibition of animated photography on the screen, has given his system the happily chosen title of the Kineopticon, and is exhibiting it at a pleasant little hall in Piccadilly Circus, where we had an opportunity on Saturday last of witnessing the display.

The subjects on the programme included the arrest of a pickpocket, an exciting street scene; a carpenter's shop, showing work in full swing; a visit to the Zoo; a boxing match; the German Emperor reviewing his troops; the 1895 Derby; a rough sea at Dover; and other attractive views. The realism and success of the views, particularly in the case of the horse race and the breaking waves, are remarkable, and should ensure the kineopticon wide popularity.

THE AERIAL GRAPHOSCOPE.

ON the 18th inst. Mr. Eric Stuart Bruce gave a demonstration at the Kensington Town Hall of the capabilities of that ingenious piece of apparatus which he has christened the Aerial Graphoscope. This is familiar to many in London, since its effects were shown nightly a few years ago to visitors to the Photographic Exhibition at Pall Mall, and consists of a white lath revolving from its centre at a high rate of speed, upon which is thrown an image from an optical lantern. The result is that the picture appears as though in space.

At the demonstration, Mr. Bruce, in addition to showing pictures of statuary, &c., showed several experiments illustrating the scientific applications of his apparatus, the most interesting being, perhaps, the effect of casting a beam of light through a slit upon the screen. The beam being moved backwards and forwards formed a series of most curious forms. This experiment Mr. Bruce calls the hieroglyphic effect. The shadow of a falling ball and of a ring whirled at the end of a string were also shown.

As a modification of the apparatus, reflections of actual objects upon a revolving lath of looking-glass were shown. In his remarks Mr. Bruce pointed out the adaptability of the apparatus to the production of stage effects, especially those in which visions or spectral objects have to be made apparent to the audience, and also its value in most experiments dependent upon persistence of vision. The apparatus appears to be still in the experimental stage, and it will therefore not be reasonable to criticise the defects which exist in it at present, as they will, no doubt, be remedied before the apparatus is offered to the public. Messrs. Harvey & Peak, of 96, Charing Cross-road, are the manufacturers of the instrument.

NOTES FROM THE WEST OF SCOTLAND.

AT a meeting of professionals held on Monday last, final arrangements were made *re* the formation of the Glasgow Professional Photographic Society. The following gentlemen were elected office-bearers: *President*, Charles Turnbull, Esq. *Vice-Presidents*, George Bell and William Whyte. *Secretary*, J. M. Laing. The meetings of the Society will be held on Mondays weekly.

A very large turn out of members of the Greenock Camera Club took place on Thursday night on the occasion of Mr. T. N. Armstrong's lecture and demonstration on *Enlarging*, with and without the aid of condensers. Mr. Armstrong showed several new and simple methods of illuminating negatives by means of artificial light. These were the outcome of a series of experiments conducted by him during the late winter, and the meeting was highly pleased at the results obtained by the lecturer by the simple methods shown.

Steady progress is being made by the Corporation officials with the arrangements for the Campbell Exhibition, which is to be held during the summer months.

THE W. H. HARRISON FUND APPEAL.

Our Editorial Table.

CATALOGUES RECEIVED.

A NEW issue of his catalogue has been sent us by Mr. Wray, of North-hill, Highgate, W. The well-known lenses of the firm are referred to in detail, special prominence being given to the Platystigmat, a lens possessing, as we have already informed our readers, the properties of great flatness of field combined with freedom from astigmatism.

THE Birmingham Photographic Company, of Great Charles-street, Birmingham, send us their latest catalogue, which, in addition to particulars of their print-out and bromide papers, also contains prices and illustrations of many clever and useful items of photographic apparatus likely to attract the patronage of amateur photographers.

THE Autotype Company, of 74, New Oxford-street, W., forward us their March price-list of tissue and materials for carbon printing. Attention is specially directed to the fact that the Company now supply sample packets of tissues and transfer papers in three sizes (12×10, whole-plate and half-plate), and that the Daylight tissue is manufactured in ten colours, instead of four, as hitherto. Other additions are some fresh spotting colours, "R. R." single transfer (prepared on Rives paper), and matt-surface single transfer.

Ross & Co., 111, New Bond-street. Two handsomely got up and well-printed catalogues reach us from Messrs. Ross. No. 1 deals with a bewildering array of lenses, shutters, field cameras, stands, hand cameras, lanterns, arc lamps, jets, and amateur photographic requirements generally. No. 2 is devoted to microscopes, telescopes, field, marine, and opera glasses, surveying, drawing, and other philosophical instruments.

THE CRITERION PRINT-OUT PAPER.

THE Criterion print-out paper is the production of the Birmingham Photographic Company, from whom we have received a sample packet for trial. The paper prints quickly, gives good, even tones, and is evidently very carefully prepared. We append the instructions for working it:—

Wash prints for ten or fifteen minutes in several changes of water, and then immerse in alum bath (2 ounces alum to the pint of water) for about ten minutes, *well wash* in several changes of water, and tone in sulphocyanide toning bath, made as follows:—

Water	20 ounces.
Sulphocyanide of ammonium	40 grains.
Chloride of gold	3 ,,

The sulphocyanide may conveniently be made up in quantity as a stock solution, and the gold also in solution, 1 grain of the latter in each drachm of water. Then, just before commencing to wash the prints, mix in the proportions given above, allowing from 1 to 1½ grains of gold to each sheet of paper. It is best to mix the quantity required for the day's prints, using a fresh bath each time. This bath will give warm or black tones. For black tones, tone till, on examining by *transmitted* light, all the red has disappeared from the shadows.

After toning, well wash in several changes of water, and fix for ten minutes in hyposulphite of soda 3 ounces, water 20 ounces, fresh each time. *Wash* in running water, changing and draining frequently for one to two hours.

Photographic Surveying.

By E. Deville, Surveyor-General of Dominion Lands. Ottawa: The Government Printing Bureau.

In this work the author first deals with descriptive geometry, perspective, and perspective instruments, and then enters fully into the use of the camera for survey work. A chapter is devoted to Hurter & Driffield's investigations, and succeeding sections exhaustively discuss photographic operations, field work, plotting the survey and photographs on inclined plates. The author writes in praise of the anastigmatic lenses for survey work. Nearly 300 illustrations and diagrams are given, and the book is one calculated to be of extrem value as a guide to survey work by means of photography.

News and Notes.

Ipswich Y.M.C.A.—A Camera Club has been formed in connexion with the above. The officers are as follows:—*President:* Mr. Josiah Runels.—*Vice-President:* Mr. Evan Edwards.—*Committee:* Messrs. Bennett, Douthwaite, Hill, Hutchinson, and Southgate.—*Hon. Treasurer:* Mr. B. C. Ridley.—*Hon. Secretaries:* Messrs. F. H. Smith and E. H. Collar.

The Photographic Club.—The next weekly meeting of the Club will be held in the Club-room at Anderton's Hotel, Fleet-street, E.C., at eight o'clock on Wednesday evening, April 1. Mr. E. J. Wall will discourse upon *The Composition of the Negative Image and its Relation to Speed Readings and Printing Qualities.* Visitors will be welcomed by the members.

Mr. Wilfred Emery, of 3, Soho-street, Soho-square, W. (two doors from Oxford-street), writes: "I herewith enclose a notice of my removal from South-street to new offices and showrooms at 3, Soho-street. Owing to the rapid increase in my business, I considered it advisable to do so, as my new offices are in the centre of the wholesale photographic trade, and therefore more easily reached by my customers."

Gospel Oak Photographic Society.—On March 17 this Society held its General Meeting, Mr. G. A. Powell in the chair, and the following officers were elected for the ensuing year:—*President:* Rev. H. LePla.—*Vice-President:* Mr. F. H. Hall.—*Committee:* Messrs. W. Beyer, J. Gittens, J. Hingston, J. Pridham, and C. Stone.—*Treasurer:* Mr. W. H. Rollason.—*Hon. Secretary:* Mr. W. A. Palmer, 13, Dale road, Kentish Town.—*Assistant Hon. Secretary:* Mr. H. Billingsley.

The Hackney Photographic Society's Third Annual Dinner was held at the Grasshopper Hotel, Gracechurch-street, on Tuesday, March 17, Mr. E. J. Wall (the President of the Society) being in the chair. About sixty members and friends were present, including Mr. T. Fall, Mr. Debenham, Mr. Bedding, Mr. J. A. Sinclair, Mr. Welford, Mr. Oakden, Mr. Mackie. The toast of the Society was given by Mr. J. A. Sinclair, and other toasts were: "The Officers" (in reply to which the Hon. Secretary, Mr. W. F. Fenton-Jones, indicated that the Society was in a most prosperous position), "The Press," and "The President." Music, recitations, and a diverting ventriloquial entertainment contributed to the success of a very pleasant evening.

Royal Institution.—The following are the lecture arrangements after Easter:—Professor James Sully, of University College, London, three lectures on *Child-study and Education;* Mr. C. Vernon Boys, three lectures on *Ripples in Air and on Water;* Professor T. G. Bonney, two lectures on *The Building and Sculpture of Western Europe* (the Tyndall Lectures); Professor Dewar, three lectures on *Recent Chemical Progress;* Mr. W. Gowland, three lectures on *The Art of Working Metals in Japan;* Dr. Robert Munro, two lectures on *Lake Dwellings;* Professor W. B. Richmond, R.A., three lectures on *The Vault of the Sixtine Chapel;* Mr. F. Corder (Curator of the Royal Academy of Music), three lectures on *Three Emotional Composers—Berlioz, Wagner, Liszt* (with musical illustrations); Mr. E. A. Wallis Budge, of the British Museum, two lectures on *The Moral and Religious Literature of Ancient Egypt.* The Friday evening meetings will be resumed on April 17, when a discourse will be given by M. G. Lippmann on *Colour Photography.* Succeeding discourses will probably be given by Professor G. V. Poore, Colonel H. Watkin, C.B., Professor Silvanus P. Thompson, Professor J. A. Ewing, Professor J. A. Fleming, and other gentlemen.

Croydon Camera Club.—Sixth Annual Dinner.—The above was held in the large dining-hall of the Greyhound Hotel on Wednesday, the 18th inst., when a full gathering of members assembled under the chairmanship of Mr. Hector Maclean (the President of the Club), who was supported by Mr. F. A. Oldaker (chairman of the Surrey Art Circle), Mr. Thomas Bedding (editor of The British Journal of Photography), Mr. Walter D. Welford (editor of the *Photographic Review*), and other gentlemen of photographic standing. The toast of the evening, "The Croydon Camera Club," was proposed by Mr. Bedding, and acknowedged by the President, who, in the course of his reply, which touched upon a large number of topics, read a letter from his Worship, the Mayor of Croydon, in which the latter signified his pleasure to preside at the forthcoming lantern show, on the Wednesday following, an announcement which was hailed with loud cheers. "The President" was proposed by Mr. James Packham in eloquent terms, which were duly endorsed by vociferous musical honours. Other toasts were "The Visitors," coupled with the names of Messrs. Wreford and Walter D. Welford, the latter of whom made a lively and humorous reply; "The Secretaries and Executive" (Messrs. Frost, Burn, and Holland); "The Photographic Press;" "The Stewards" (who were Messrs. Waller, Frost, Hurst, and Wreford); finally "The Ladies," who were in charge of Messrs. Hurst and S. H. Wratten. The musical programme was unusually full and attractive. Mr. Claude Packham's violin solos were vastly appreciated, as also were the effectively delivered ballads of Mr. Keough, and the declamatory rendering of "The Execution of Montrose" by Mr. Thornton. Mr. Walter D. Welford's selections upon a one-stringed Japanese fiddle gave much pleasure, and created considerable wondermert at the range of sound emitted. There was also plenty of fun in "Up came Johnny with his Camera" (Mr. Frost), and in the vocal comicalities of Messrs. Bown and Burns, jun. Others who contributed various items to the entertainment programme were Mr. H. E. Holland, Mr. J. Burn, Mr. A. Jenkins, Mr. S. H. Wratten, and Mr. A. E. Isaac.

Patent News.

The following applications for Patents were made between March 11 and March 18, 1896:—

Shutters.—No. 5340. "Improvements in Shutters for Photographic Cameras." E. S. B. Hughes.

Cameras.—"No. 5454. "Improvements in Parts of Photographic Cameras." J. B. Brooks.

Printing.—No. 5494. "A Material for Photographically Printing upon both its Surfaces." H. Maclean.

Artificial Light.—No. 5637. "Improvements in Means for Illuminating Objects for Photographic and other purposes." Complete Specification. Y. Schwartz.

Mounts.—No. 5695. "An Improved Picture Mount for Photographic and other Albums and the like, applicable also for Binding Loose Papers or Sheets and Samples." M. G. Amson.

Photographic Apparatus.—No. 5699. "An Improvement in Photographic Apparatus." B. Acres.

Chrono-photographic Apparatus.—No. 5758. "Improvements in Chrono-photographic Apparatus." F. Gossart.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

March.	Name of Society.	Subject.
30	Leeds Photo. Society	*Some Account of the Photographic Convention of 1895.* J. H. Walker.
30	North Middlesex	Informal Meeting.
30	Richmond	*Platinotype.* T. H. Stringer.
31	Bournemouth	Discussion on Exposure and Exposure Meters.
31	Brixton and Clapham	*On Making Enlarged Negatives.* M. Atkinson.
31	Hackney	Members' Auction.
31	North Surrey	Prize Slides.
April.		
1	Croydon Camera Club	Second Novices' Night: *How to Make a Good Negative.*
1	Derby	*Notes on Landscapes.* F. L. Pither.
1	Edinburgh Photo. Society	W. Ivison Macadam, F.R.S.E., F.I.C., F.C.S., &c.
1	Photographic Club	*The Composition of the Negative Image and its Relation to Speed-readings and Printing Qualities.* E. J. Wall.
2	Bradford	*Hints on Portraiture.* A. Priestley.
2	Ealing	Lantern Evening.
2	Liverpool Amateur	Lantern in Use.
3	Croydon Camera Club	Excursion: Amberley for Bury and Fittleworth. Leader, J. Smith.

ROYAL PHOTOGRAPHIC SOCIETY.

March 24,—Technical Meeting,—The Earl of Crawford, K.T. (Vice-President), in the chair.

Mr. S. Herbert Fry showed a model of McKellen's hand camera, with a new device for changing plates.

Mr. F. E. Ives read a paper on the relative colour sensitiveness of

Ordinary and Isochromatic Plates.

He said many writers had from time to time asserted that isochromatic effects could be obtained by exposing ordinary plates through yellow colour filters, but most of such writers—like others who claimed that orthochromatic results could be obtained in daylight with commercial orthochromatic plates without a colour filter—did not know what they were talking about. Nevertheless, inasmuch as it was true that, with suitable colour filters, orthochromatic effects could be obtained with extremely rapid ordinary gelatino-bromide plates, it was reasonable to suppose that some of these workers might have proved the fact before they made the assertion. He believed, however, that the first practical demonstration of the possibility of not only obtaining orthochromatic effects with ordinary plates, but of perfectly controlling the relative action of the different spectrum rays so as to render all the colours in photometrically accurate relation to each other, was made by himself, in Philadelphia, in 1886, in which year he showed at the Franklin Institute a reproduction of a high-class chromo-lithograph, the colours of which were more accurately rendered on an ordinary plate than in a photograph of the same subject made by Dr. Vogel to prove the capabilities of his

then secret azaline process. Having referred to various publications in which his communications upon the subject had appeared, he proposed to confine himself principally to an exhibition and explanation of the results of various experimental tests, any half-dozen of which he was prepared to repeat at the conclusion of his paper. His test object consisted of six squares of glass—white, cobalt blue, signal green, chromium green, pot yellow reinforced with brilliant yellow dye, and ruby red—over which he had placed a film photograph of a geometrical pattern with shaded lines, which helped to make evident to the eye the relative amount of action in the different squares in the reproductions. Four photographs of the test plate were shown, two on isochromatic plates with a screen of a very good medium pot yellow glass, the third on an ordinary plate with Dr. Vogel's aurantia colour filter, and the fourth on an ordinary plate through a very light colour filter of naphthol yellow and multiple yellow, the last-mentioned yielding an almost perfect result. A series of slides was next shown, for the purpose of demonstrating the distribution of colour sensitiveness, and the relation of green, yellow, and red sensitiveness to blue sensitiveness in the various commercial orthochromatic plates; the effect of exposure on an ordinary plate without a colour filter, through medium and deep chrysoidine and deep cobalt blue; and the effect of exposure of an isochromatic plate through a combination of brilliant yellow and medium fuchsine, and of a variety of plates through a combination of naphthol yellow and multiple yellow. Further slides appeared to show that it would be possible to obtain orthochromatic photographs on ordinary plates with exposures not more than two or three times longer than was necessary with one make of commercial orthochromatic plates, and six and a half times longer than with another highly praised orthochromatic plate, but that 160 times longer was required than with certain green sensitive plates; these figures, however, were modified by varying conditions. The next slides were intended to show the uselessness of yellow glasses, and aurine, multiple yellow, and chrysoidine colour filters with ordinary plates. Aurine, although represented in Dr. Eder's *Handbook* as completely absorbing the blue end of the spectrum, was worse than no screen at all, since it only served to reduce the action in the green; multiple yellow was equally useless; deep chrysoidine (chrysoidine being also represented in Dr. Eder's *Handbook* as completely absorbing the blue end of the spectrum), and chromium green, were also unsatisfactory. Although certain special colour filters gave better results with ordinary plates than did yellow glasses with some well-known orthochromatic plates, it should be clearly understood that with suitable colour filters equally good results could be obtained on orthochromatic plates, with shorter exposures. Some manufacturers of orthochromatic plates did not recommend yellow glasses, but supplied very good dyed colour filters; but Mr. Ives said he did not know of any such manufacturer who had admitted that it was not necessary to employ specially colour-sensitised plates in order to obtain orthochromatic photographs.

Mr. W. E. DEBENHAM asked what was meant by "multiple yellow" and "brilliant yellow?"

Mr. IVES said he did not know himself. He obtained the dyes under those names from chemists in New York and Philsdelphia, but no one seemed to know what they were.

Mr. DEBENHAM remarked that, from one of the results shown, it would appear that a chromium green light would be the best by which to develop isochromatic plates; and

Mr. IVES said that was undoubtedly the case.

The HON. SECRETARY (Mr. Chapman Jones) asked whether Mr. Ives got the maximum of action in the yellow by daylight without a screen?

Mr. IVES replied that it was only with special screens that there was the maximum in the yellow, even with electric light.

Mr. E. J. WALL, referring to Mr. Ives's statement that he differed from Dr. Eder as to the effect of aurine, asked what aurine Mr. Ives used? Aurine was extremely sensitive to light, and faded very rapidly, which might account for the difference. He had himself experimented both with aurine and chrysoidine, and his results agreed exactly with those of Dr. Eder. He fancied that multiple yellow and brilliant yellow were mentioned in Benedict's *Chemistry of the Coal-tar Colours.*

Mr. IVES said he obtained three samples of aurine, and used the yellowest. In answer to Mr. Bolas, he expressed the opinion that an exposure of from two to four times that required with an orthochromatic plate would, with an ordinary plate and a suitable screen, yield a fairly satisfactory result.

Mr. WALL asked whether it was possible to obtain an orthochromatic effect on an ordinary plate without a screen?

Mr. IVES said he knew of no means by which it could be done.

Mr. HEARSON pointed out that it was impossible to follow up Mr. Ives's investigations if the dyes to which he had referred were not obtainable.

Mr. IVES promised to give some information respecting the dyes in an appendix to his paper when it appeared in the Society's *Journal.*

Mr. T. R. DALLMEYER expressed a hope that Mr. Ives would give some attention to the subject of dying balsams for use as colour filters.

The HON. SECRETARY suggested that, in further experimenta, the direct-vision spectroscope should not be used; the use of this instrument would probably account for differences of observation between Mr. Ives and Mr. Wall.

Mr. WALL said he obtained precisely the same results with the direct-vision spectroscope as Dr. Eder got with two prisms.

Mr. IVES made some further remarks upon the use of chlorophyll and the bichromate tank, and showed a photograph of a painting copied by this process, and the meeting closed with the passing to him of a cordial vote of thanks for his paper.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

MARCH 19,—Mr. J. J. Briggingshaw in the chair.

The following presents were laid on the table: THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC for 1896 and *Photographic Surveying*, by E. Deville.

Mr. W. H. Smith was proposed for membership.

Mr. Freshwater showed two more shadowgraphs, one of a child's foot, with a deformed ankle, and one of his own foot.

THE TRAILL TAYLOR MEMORIAL FUND.

The HON. SECRETARY made a statement as to the present position of this fund, and drew attention to a letter of Mr. Drage in the photographic press with reference to a proposal that the Photographic Convention should support the same. He hoped to see a much larger sum collected than at present to hand, and thought no effort should be spared until at least 350*l.* was obtained. When it was remembered that Mr. Traill Taylor had always been willing to give them information and aid in the way of lectures, he considered the members should feel it their duty, and that they owed it to his memory, to see that the fund did not lack support, and he proposed therefore that a subscription list should be started amongst those members who had not already subscribed.

Mr. A. E. SMITH said it had been asked whether it was worth while to turn a portrait lens round for enlarging. He had found it a great advantage, and showed photographs demonstrating this, the image being sharper on reversing the lens.

COPYING.

Mr. H. C. RAPSON read a paper on this subject. [See page 200.]

The HON. SECRETARY had been much interested in the paper, especially with reference to the method of avoiding vibration. He had seen an arrangement adopted by Mr. Smith, whose business premises were over a let of machinery, and on the top floor and from the rafters he suspended a cradle by four stout ropes, which carried all the apparatus for copying, and he thought it a grand idea. With reference to the superiority of the new lenses for copying purposes, it was true there was freedom from astigmatism, but one was not bound to use a wide angle. He considered the old form of rectilinear gave as good results, if not better, and thought it was a moot question whether some of the newer forms were superior in point of copying. With a moderate angle, he believed it probable that an older lens would yield better results than the recent forms.

Mr. SMITH had found the new lenses no worse than the old. He said the cradle he used took off quite ninety per cent. of the vibration.

Mr. RAPSON, in reply to some questions, said he had given up the rectilinear lens in favour of the new Goerz, which he found much superior. That he previously used was a very good French rectilinear lens of twelve inch focus. In reducing very much, say, from eighteen inches high to three inches high, he could not get perfect definition with a larger atop than *f*-22, while with the Goerz he could get perfect definition over a half-plate with full aperture, *f*-7·7.

Mr. A. MACKIE said a long exposure to weak light was not the same as a short one to a brilliant light, and for that reason the newer lenses, which enabled a shorter exposure to be given, would be advantageous, other things being equal.

Mr. RAPSON, questioned by Mr. Mackie, did not like isochromatic plates for copying. He had found a difficulty in keeping them absolutely clean.

Mr. MACKIE had, on the contrary, found them very clean. In copying old silver prints he would like to know the way Mr. Rapson preferred to light it. The difficulty was to get rid of the grain.

The CHAIRMAN had also experienced difficulty in the matter of grain and reflection. He thought the best way was to place the print a little to one side of a window.

Mr. RAPSON'S studio was all glass, and he had a flood of light on all sides, which he reflected from the floor by a piece of white paper.

Mr. MACKIE preferred a very oblique source of light. With unmounted silver prints he had found it a good way to wet and mount the print on glass, backing up with blotting-paper. When the prints were stamped on the back, however, unless they were first removed, these would show through, and he got rid of them with a little sulphite of soda.

Mr. ATKINS said soap and water would also remove them.

Mr. HADDON stated that, in the event of prints so mounted being allowed to dry, they could be removed with a mixture of a drachm of hydrofluoric acid in three or four ounces of water without damage.

Mr. TEAPE had found it best to place the print between two sources of light rather than using one only.

The HON. SECRETARY said he would be interested to hear of some experiences with uncorrected lenses for copying. The thinness of the glass would probably be an advantage.

Mr. MACKIE said if sufficient brains were used with the lens, no doubt an uncorrected one would answer.

Mr. RAPSON thought the advantages would not be sufficient to compensate for the stopping down. For regularity of result he emphasised the timing of development, which was an enormous power. For copying photographs, he had found three times the period between the commencement of development and the appearance of the image as sufficient.

PHOTOGRAPHIC CLUB.

MARCH 18,—Mr. Crofton in the chair.

The HON. SECRETARY announced a series of lectures upon the chromium salts, which would be held at the rooms of the Royal Photographic Society on Friday evenings, commencing in Easter week.

Mr. SNOWDEN WARD proceeded to deliver his lecture on the

NEW PHOTOGRAPHY.

Mr. Ward, who was assisted by Mr. Robins, had a good array of the apparatus necessary for his demonstration. His intensity coil was made by Hurst & Co., of London, and is capable of giving a six-inch spark, although he (Mr. Ward) does not work at so high a tension. Secondary batteries are used as the source of current, on account of the facility with which they can be recharged in most large towns. A supply of both old and new patterns of radiant matter tubes, supplemented with Newton's latest device, the "focus" tube, and some of the more toy-like electrical apparatus of the Geissler tube order, were on the table before him. Mr. Ward, in a few well-chosen fore-

words, said his lecture would be partly of the elementary and partly of the advanced type—elementary for such as wanted to see the phenomena which produced the new results, advanced for those who desired to be acquainted not only with the latest work done, but with the side issues and workings of our own and Continental scientific men. Mr. Ward said that many of the most recent discoveries were but the exhumation of a previous burial, and that many of the phenomena now noted had been already discovered and discarded. He mentioned that, many years since, Sir Benjamin Richardson had been able to note the structure of the skeleton of a young thin person when illuminated by burning magnesium. Röntgen's discovery was based upon the work of Crookes, Hittorf, Lenard, Tesla, and others, who found that the high-tension current in an almost closed circuit passes the gap between the terminals in sparks; but that, if this gap be enclosed in a vacuum, the nature of the discharge entirely changes, and becomes a fluorescent glow, which depends for its colour upon the nature of the residual gases and the chemical constitution of the glass tube which surrounds the vacuum. As the vacuum becomes complete, the glow in the tube practically ceases, and the glass itself becomes fluorescent. Hittorf and Crookes very thoroughly examined this phenomenon, and the latter founded his theory of radiant matter thereupon. Other investigators found that the rays of which this glow appears the outward and visible sign possess the potentiality of passing through substances which are ordinarily regarded as opaque. Röntgen has practically demonstrated this, and given the fact prominence. Like many other discoveries, this one was accidental, but all credit is due to Professor Röntgen for completing the series of observations in the character and properties of the X rays. The most practical portion of Mr. Ward's remarks were, perhaps, contained in his suggestion that, if a worker were content to use the older form of tube, requiring an exposure of five to ten minutes, very reliable results could be expected to ensue.

Mr. ROBINS then made a radiograph of a pair of pince-nez in a wooden case, and the developed negative was shown upon the lantern screen.

Mr. FRANK HAES asked the Club to express their gratitude to Mr. Ward for all the time and trouble which he had expended, and for the most interesting lecture; and the Club did so, and evinced their interest in the matter by an interesting discussion of a somewhat discursive character, in which Messrs. Cowan, Child Bayley, Fry, Bridge, and others took part.

Questions were asked as to the preferential suitability of fast or slow plate films and paper for purposes of radiography, the cost of apparatus, the effect of an extra-thick or thin coating of emulsion; but the lecturer said that at present there was nothing like unanimity of opinion amongst workers, and that, as a matter of fact, the action of the "tubes" was so irregular that the time for determining these other and more photographic details had hardly arrived.

Mr. WARD mentioned that a radiograph had been made through a packet containing a dozen sheets of bromide paper upon a dry plate, and that an equally good image had been obtained upon all the sheets of paper and upon the plate underneath.

MANCHESTER PHOTOGRAPHIC SOCIETY.

MARCH 12,—Mr. F. W. Andrew in the chair.

The following gentlemen were elected members:—Messrs. T. M. Brooke, F. W. Burton, J. Evans, J. H. Holland, S. H. Tiller.

Mr. F. W. Masters exhibited a most ingenious stereoscopic hand camera of his own manufacture, embodying many good features, including a rising front with finder attached, the mirror being an inclined plane rising or falling as the front is raised or lowered.

Mr. H. V. Lawes showed some excellent specimens of objects impressed on the sensitive plate by means of the X rays, the work of Mr. Dorman.

Mr. A. BROTHERS, F.R.A.S., then gave an outline of a method of

PHOTOGRAPHING THE CORONA WITHOUT AN ECLIPSE,

and illustrated his remarks by lantern slides. In 1860 an expedition was sent to Spain in order to find whether the red flames were of the sun or moon, and, by photographs and drawings taken while the moon passed in front of the sun's disc, it was found that they were of the sun. Slides were then passed through the lantern of the sun's flames taken without an eclipse by Mr. Packer, of Birmingham, by means of a pinhole camera and a very thin sheet of copper, lead, or aluminium placed in front of the plate, the results being very remarkable.

There were next shown on the screen several examples of the New Photography, lent by Mr. J. T. Chapman, and described by Mr. Brothers.

Brixton and Clapham Camera Club.—March 17, Mr. J. W. Coade (President) in the chair.—Mr. W. BIDDELL gave a lantern lecture,

THE MONASTERIES OF ESSEX.

It was soon evident that Mr. Biddell is both an enthusiast and an authority on the antiquities of this country, and has also the gift of interesting his audience, and of conveying to them a vast amount of information in a pleasant manner. In addition to well-known abbeys and priories, as Barking, St. Osyth's, Coggeshall, Stratford Langthorne, Waltham, Beeleigh, &c., he has made it his business to search out all possible traces of many less familiar monastic houses, the remains of which have, in many instances, been used for farm buildings or have entirely disappeared. Besides recent photographs of existent ruins, Mr. Biddell shows a number of slides copied from old prints and engravings, thus enhancing the value and completeness of his series, which well deserved the attention they received from the audience. The Society have decided to hold quarterly competitions open to all members. The closing date for the first is June 16, and the subject landscape. A bronze medal and certificates will be awarded. It is also proposed to hold an exhibition of members' work in October next.

Camera Club.—Those of our readers who attended the last meeting of the Photographic Convention at Shrewsbury will remember a large frame containing a number of prints, direct and enlarged, treated in various ways on one sheet of bromide paper. It was the work of Mr. Luboshez, who was present at the Shrewsbury Exhibition to represent the Eastman Company. This gentleman gave an interesting discourse on portraiture at the Camera Club last Monday week, and, as a demonstration of the

ELECTRICAL APPARATUS MADE BY MESSRS. NALDER & HARRISON

for studio work was arranged for the same evening, the speaker and the exhibitors joined forces in a very happy manner, and, while several exposures were made under the reflected beams of the electric light, Mr. Luboshez was able to talk of posing, the various ways of lighting a model, and to demonstrate his method of developing the resulting negatives. The lesson was a valuable one to those who practise portraiture, as well as to those who are thinking of doing so; hence there was a good attendance of members. The Nalder & Harrison apparatus worked well. It consists of a hand-fed electric arc lamp, the two carbons being set in holes pierced in the sides of a cup of white marble or other refractory material, which becomes heated sufficiently to add its quota of softened light to the total luminosity produced. This cup is set in the focus of an umbrella-like reflector, and prevents the direct light from the white hot carbons from reaching the sitter. After several portraits had been taken of Lord Crawford and others, the lecturer proceeded to develop the plate. He agreed with all other workers that little or nothing can help out an under-exposed negative, it is a waste product, for which no use can be found; but he asserted that an over-exposed plate could be turned into a good negative provided that it had not received more than 100 times the normal amount of exposure. Acting on the presumption that a plate was much overdone in the matter of light access, he would proceed to develop it in the most tentative manner, using a very much diluted agent—be it pyro, metol, or anything else—until the image appeared. He could now tell, by its behaviour, how to proceed. If it showed signs of over-exposure, it was immediately placed in a one per cent. solution of bromide, and allowed to remain soaking therein for about five minutes. The development of the plate is then proceeded with warily, and, should there be a threatened want of density, the developer alone—*i.e.*, without accelerator or retarder—is applied to the plate until the required result is brought about. If this method be carefully followed, any amount of density can be obtained on a plate which otherwise, in consequence of over-exposure, would be thin, flat, and in every way unprofitable. Several excellent Röntgen pictures of hands, feet, &c., have recently been taken at the Club under the able manipulation of Mr. Powles, of the Electrical Standardising Institute, Faraday House.

Croydon Microscopical and Natural History Society (Photographic Section).—March 20.—A numerous and appreciative audience assembled at the School of Art room, Public Hall, to witness the final lantern exhibition of the season. The first part of the programme was devoted to members' slides. Mr. A. Roods contributed an excellent series of views of Hartfield, Groombridge Place, Lingfield, Oxted, Godstone, and Lewes. Mr. Alfred Underhill followed with a collection of photographs of Croydon, Beddington; snap-shot street scenes, views of the Tower Bridge and river Thames; also pictures of Guildford, Dorking, and Ramsgate. Mr. Hoole, of Sutton, showed a number of fine slides of the Norfolk Broads, &c., which were deservedly admired. The second part consisted of a short paper by Mr. J. H. BALDOCK, F.C.S., on Professor Röntgen's X rays, illustrated by diagrams made by himself and slides kindly lent for the occasion by Mr. Campbell Swinton.

Dulwich Photographic Society.—March 17.—The Committee having accepted, with great regret, the resignation of Mr. E. Beer, the Hon. Secretary owing to pressure of business, Mr. Herbert J. Ellis, one of the founders, was unanimously elected to fill that post pro tem. Two new members were elected and three more proposed (among the latter a photographic chemist), the members proceeded to the last Exhibition this season of their lantern slides, to which a large number of visitors were admitted. A new member (Mr. Mitchell) was applauded for a pretty scene from Ladywell Recreation-ground, one of Windsor Castle, and also a pleasing slide of Eynsford. Mr. Beer's slides of Kingsgate Castle, Broadstairs Pier, and Ramsgate Harbour were much praised, as were Mr. G. E. Smith's views of Hastings Castle. Mr. H. Jackson's views of Old Champion Hill Station (now East Dulwich), Lock House, Sunbury and Marlow Church were most effective, also the slides of Mr. Herbert J. Ellis, who exhibited portraits of different members and views of river scenes, &c. The Society would be pleased to hear from those wishing to become members. Address Herbert J. Ellis, Constitutional Club, East Dulwich-grove, S.E.

North Middlesex Photographic Society.—March 16.—Mr. H. STUART gave a paper on

ENLARGED PAPER NEGATIVES.

He told how paper negatives were made long before glass plates were in use; but, whereas the exposures for landscapes then necessary ran into hours, it was very different now. He used mostly Ilford smooth slow bromide paper for the enlarged negatives, placed in the dark slide of an enlarging camera, the paper backed up by cardboard or glass to keep it flat. The paper print to be enlarged from was fixed on a sliding screen in front of the camera, with a piece of glass superimposed to keep it in position. This was exposed to daylight for about ten minutes in summer to an hour or more in winter, according to the light. It could be developed as an ordinary bromide print, but carried further, and could be intensified if necessary. He showed numerous negatives and prints therefrom in carbon, bromide, and silver, some from waxed negatives, and others from unwaxed. The carbon process seemed best suited to the negatives, as the slight grain was less apparent than with the other processes. The paper provoked some discussion as to the advisability or otherwise of waxing, except in the case when quickness of printing was necessary, and various mediums were recommended.

Putney Photographic Society.—March 18, Dr. Cuthbert Wyman presided. —The CHAIRMAN remarked that the lantern-slide competition which should have taken place that evening had been unavoidably postponed to April 29, on which occasion Col. Gale, F.R.P.S., has kindly consented to act as Judge. The subject of the evening being "lantern-slide making," Mr. W. C. Plank pro-

ceeded to explain the whole process, and described the necessary apparatus for making slides by contact and reduction, after which Mr. Wm. Martin (Hon. Secretary) exposed and developed some lantern plates which were then passed through the lantern, and slides by Messrs. Colebrook and Staunton were also shown. Mr. F. T. Becson gave some useful hints on this subject during the discussion that followed.

Richmond Camera Club.—On Monday, the 16th inst., the Richmond Camera Club gave an exhibition of lantern slides before the Richmond Athenæum, an old-established local institution. The evening, which was further enlivened by recitations and music, passed off very successfully. The programme of the photographic portion of the entertainment was as follows: 1. Some French cities and Ceylon, twenty-four slides by Mr. J. D. Gibson. 2. Local views, six slides by Mr. F. Neville. 3. Seaside views, eight slides by Mr. P. Ennis. 4. English scenery, seventeen slides by Mr. G. Ardaseer. 5. Pompeii, twenty-four slides by Mr. C. H. Davis. 6. Miscellaneous, six slides by Mr. H. A. Dimsdale, eight slides by Mr. R. Skone-James, and twelve slides by Mr. J. H. Williams. 7. The Land of the Broads, fifteen slides by Mr. C. J. M. Child. 8. Richmond (Yorks), eighteen slides by Mr. J. B. Hilditch. 9. Spanish scenes, twelve slides by Mr. E. D. Purcell. 10. Granada and the Alhambra, twenty-four slides by Mr. F. P. Cembrano, junr.

Bradford Photographic Society.—March 19.—Mr. Cecil Wray, A.M.E.E., gave a popular lecture, entitled

Phonographs, Kinetoscopes, and the Kinetograph.

Mr. Wray divided his lecture into two parts, the first being devoted to the rapid advancement of these inventions, and a clear explanation of the different apparatus. The second part was devoted to the practical demonstration of the commercial Edison-Bell phonograph as used in lieu of a short hand clerk. Musical records, songs, whistling solos, and recitations were rendered, and a recitation by one of the members present was taken into the phonograph and repeated by the instrument, to the amusement of all present. At the close a hearty vote of thanks was accorded to Mr. Wray for his very instructive and entertaining lecture, which he briefly acknowledged, and promised as soon as he had completed a kinetograph, which he had in course of construction, he would be pleased to give a demonstration with it before the Society, thus enabling a roomful of people to see on a lantern screen moving pictures, the same as those in the kinetoscope, but on a larger scale.

Derby Photographic Society.—March 17, Mr. A. B. Hamilton in the chair.—Mr. Harold Baker, of Birmingham, gave a lantern lecture on the

Avon Valley,

and the lecture was illustrated by considerably over 100 slides of a very high order of merit. Mr. Baker dealt in a very interesting manner with the natural and archæological features of the district, the views of the river scenes, the church interiors, and the old monuments shown on the screen being deservedly appreciated. The concluding meeting of the winter session will be held on April 1, when a paper by Mr. F. L. Pither, entitled *Notes on Landscapes*, will be read.

Liverpool Amateur Photographic Association.—A lecture was delivered by Mr. Eadweard Muybridge in the City Hall, Eberle-street, on the 19th inst., in connexion with the above Association. The subject of the lecture was

The Motion of the Horse and other Animals in Nature and in Art.

Mr. Muybridge described in detail the various movements which make up the canter, trot, gallop, and other movements of the horse, and illustrated his remarks by an admirable series of photographs exhibited by the oxyhydrogen light.

Moseley and District Photographic Society.—March 20, Captain Davidson (Vice-President) in the chair.—Mr Adams was enrolled as a member. The Hon. Secretary passed round for inspection a print showing spotty markings all over, and asked for suggestions as to the cause. Several likely causes were suggested, and amongst them "the influence of unevenly mixed emulsion on the P.O.P." The Secretary then stated that all were wrong, and it was caused by the negative (a thin one) during printing having raindrops on the glass of the printing frame. Captain Davidson suggested they had been had on toast. Dr. Radcliffe then delivered his excellent lecture on

Home Portraiture.

He remarked that, no doubt, the amateur would be tempted at some time or other to take portraits of his friends and relations, and it was quite possible and even probable by so doing to make them enemies for life. Different to the landscape, &c., the subject and lighting was quite under control of the operator, if he had a few accessories for regulating the light. He gave diagrams for lighting the room of one and two windows, and stating the best single window was that known as a bay window. He suggested that a graduated background would often be very advantageous in many cases, bringing into greater prominence the lighting on the face. What made him take more to portraiture than other branches of the art was the fact that he had early learned the art of retouching—not excessive retouching as practised by professionals, but just evening up of the irregularities caused by the different actinic colours of the flesh and photographic exaggerations. Many and useful were the hints given, and highly were they appreciated by the members present. The Hon. Secretary then made a few remarks respecting various points that had been raised, and made a few further suggestions which he thought might be useful to the beginner or home portraitist. Mr. Williams then said that he thought it quite unnecessary to make comments on what the lecturer had said, and thought it very presumptuous of the Hon. Secretary to take upon himself the criticism and discussion of the paper Dr. Radcliffe had so kindly given. The Hon. Secretary then called attention to a by-law which asked for comment, criticism, and discussion, and stated that he thought the greatest benefit to a Society would accrue from free and unrestrained criticism. He was sorry if he had not paid sufficient deference to the lecturer, for he felt that the greatest praise was due to the lecturer, Dr. Radcliffe, for his very excellent and instructive lecture, and proposed as a vote of thanks that the lecturer take the fullest and most sincere thanks of an interested and instructive meeting. Mr. Williams seconded.

Glasgow and West of Scotland Amateur Photographic Association.—March 16.—Mr. Stewart Smith lectured on

The Röntgen Rays and How to Use Them.

He pointed out what Professor Röntgen had discovered, and indicated some of the probable applications of the rays. After describing some of the more remarkable phenomena which have been observed, he showed Crookes' and other forms of vacuum tubes in action, and explained the method of making exposures. At the conclusion of Mr. Smith's paper, Dr. John MacIntyre made some remarks on the subject, and referred to the cryptoscope, which he thought would be largely used for surgical work, although the photographic method would also have its place. He said that, although not at liberty to make any definite statement, he had information which led him to expect an important development of the cryptoscope within a few days. Dr. MacIntyre then showed on the lantern screen a number of his results, including human hands, feet, elbow and ankle joints; fish and frog, showing the skeleton very distinctly; also an interesting case, in which unsuspected disease of the bone had been found while searching for an embedded needle. He pointed out that in many cases the structure of bone was clearly shown.

Correspondence.

☞ *Correspondents should never write on both sides of the paper. No notice is take of communications unless the names and addresses of the writers are given.*

THE TRAILL TAYLOR MEMORIAL FUND.

To the Editors.

Gentlemen,—Mr. R. P. Drage, the Hon. Secretary of the Photographic Convention, has recently drawn attention in the press to the Traill Taylor Memorial Fund, and expressed the hope that the photographic societies will do their best to promote this good cause.

As the Secretary of the London and Provincial Photographic Association, I beg through your columns to appeal to my brother Secretaries throughout the country, and ask them and every member of a photographic society, who knew the late Mr. J. Traill Taylor, either personallly, or through his writings, to give this fund earnest and active support. The Committee have collected nearly 200*l.*, but this sum is quite inadequate to accomplish the purpose they have in view—the endowment of a lectureship.

The time has now come when the fund should be increased by smaller donatione in large number, and the photographic societies are the best centres at which subscription lists could be opened. There are nearly 300 societies, and if each Secretary would open a list for small donations, as we have done at the London and Provincial, adding to it, if possible, a subscription from the Society collectively, it is certain that sufficient funds could be raised to make the Traill Taylor Lectureship of such importance, that men of high scientific ability and art training would esteem it an honour to give these lectures. Such a stimulus to photography is greatly needed in this country, where we look to public or private appreciation to do that which in many other countries is done by the State.

Ever willing to give advice and that of the best, because of his great experience and sound judgment; ever ready to promote a worthy photographic movement; ever ready to help a society, or a brother photographer, Traill Taylor was one of the most useful men of his time. Those who had the privilege of knowing him must feel how well deserved is this tribute to his memory, and to those especially would I appeal to bring this fund under the notice of the societies to which they may belong.

By such means only can success be ensured.—I am, yours, &c.,

88, *Evering-road, N.* Philip Everitt.

KINETOSCOPY ON THE SCREEN.

To the Editors.

Gentlemen,—Referring to Mr. Acres' letter in yours of the 13th, stating that "a certain individual had advertised himself as being sole manufacturer of these films," and giving the impression that the successful manufacture in England was due to Mr. Acres alone, it is due to me to state exactly what occurred, leaving your readers to form their own judgment.

In December 1894 I was manufacturing kinetoscopes, and my friend, Mr. S., suggested that if I would construct a camera for taking the films he would introduce me to Mr. Acres, who could undertake the photography. On February 4 Mr. Acres called at my works, and agreed that, if I constructed the camera and tools at my own risk and expense, he would use it for taking films for me solely. He also handed me a sketch of an apparatus for photographic printing, and suggested that some of

the actions of this might be utilised for the camera. I pointed out that this could scarcely be done, and of seven mechanical motions embodied two were abandoned, and the remainder replaced by different actions suggested by Mr. S. and myself, only one unimportant piece being retained.

On February 5 and 6, 1895, I designed and constructed (with the co-operation of Mr. S.) a working model. By March 16 I had made drawings of, and finished, a complete kinetograph, for which Mr. Acres found a lens, but in designing the mechanism of which he took no part. Before this was finished, Mr. Acres verbally undertook to share the patent with me. After the kinetograph was tried and found satisfactory, Mr. Acres said he withdrew from this undertaking, and stated that he would purchase the camera, but claimed that he had a right to patent it himself.

On March 28, finding that Mr. Acres insisted on this, and that during the delay the demand for films was rapidly falling off, I gave in upon this point, Mr. Acres signing an agreement to produce films for me for a term of years from that date, and on March 30 our first saleable picture—viz., *The Boat Race*—was taken.

On July 12, 1895, Mr. Acres stated that he was no longer in a position to make films without being financed, and the agreement was cancelled on his paying for the outfit and compensation. Since then I have constructed a kinetograph on an entirely new principle, which enables me to obtain increased accuracy in the manufacture of the films.—I am, yours, &c., ROBT. W. PAUL.

44, *Hatton-garden, London, E.C., March* 17, 1896.

P.S.—Referring to the second paragraph of Mr. Acres' letter, I have submitted the matter for the opinion of Mr. Fletcher Moulton, Q.C., with the following result:—

1. Mr. Moulton is of the opinion that Mr. Friese Green's patent is limited to the actual details of working described by him, in conjunction with the use of the double lantern, none of which I, in any way, embody in my system.

2. Having submitted to Mr. Moulton the specifications of all kinetoscope projection apparatus, he states that my apparatus in no way infringes upon any of these.

PHOTO-CHROMOSCOPES.

To the EDITORS.

GENTLEMEN,—Mr. Ives's ideas of "fair" and "courteous" language, as expressed in his last letter, appear to me to be somewhat hazy. I would remind him that the whole of the present correspondence has been necessitated by his use of uncourteous language and thinly veiled innuendo.

A very good example of his methods occurs in this last letter of his, when he attempts to reconcile his former contradictory assertions by having recourse to Jesuitical sophistry to define the difference between insinuating that I copied his instrument and actually saying that I did so. Unfortunately for himself, he destroys this metaphysical fabric, and appears in his true colours in the latter part of his letter, where he not only charges me with copying his apparatus, but says any improvements I claim in my own instrument are merely "tricks" with the "deliberate intention of getting around" his patent.

Let me inform Mr. Ives that this species of "courteous" argument is no proof, besides being unworthy of a gentleman, either posing as a scientist or "puffing" a patent, and is likewise an insult to your readers, to most of whom I am, perhaps, better known by reputation than Mr. Ives.

This is the language, and those are the tactics he has employed throughout the discussion, and he has no one but himself to thank if he finds himself reduced to the whine which terminates his last letter, after having so loudly claimed everything connected with colour photography.

Mr. Ives's copious extracts from U.S. specifications (which have nothing to do with British patents) may serve the purpose of a cheap advertisement, but they certainly do not prove my invention to be his, nor disprove my former description of his preposterous claims and his misleading statements.

Take, for instance, the essential points of his patent claims, as italicised by himself. Does he mean to say that he claims, "by priority of invention," the inclination of mirrors at an angle of 45° either to a vertical or a horizontal plane? If this is so—and he emphasises this point—it appears to me an example of either absolute ignorance or downright arrogance.

Again, he emphasises by italics "means for varying the angle of such instrument," &c., and would have us accept this as one of the brilliant points of his apparatus. A reference to his specification will reveal in this original (?) "means" our old friend the camera strut, a method which has been applied to every piece of inclined apparatus years before Mr. Ives was born.

As for the third paragraph Mr. Ives considers important enough to italicise, it appears to me a most invidious task to determine whether he claims to have invented a window, a light sky, or the angles of illumination!

When Mr. Ives so "courteously" insinuated that my instrument was his own "with differences of detail only," I asked what was his apparatus but the labours of others modified to suit his fancy? Mr. Ives has carefully avoided answering this, and I think it would interest your readers to illustrate my meaning in one or two points. I am obliged to Mr. Ives for calling attention to Cros's specification of November, 1888, as it very materially helps us in such an examination. After reading this it seems difficult to imagine how Mr. Ives can pretend to uphold his sweeping claims in the face of a patent which contains the whole essence of his photo-chromoscope, and dates so many years before him. Neither space nor time permits of my publishing the drawings from this interesting document, but I would advise every interested reader to obtain a copy and judge for himself. Suffice it to say, but for the introduction of his much-vaunted coloured reflectors, and putting the instrument on its side, with some other "differences of detail only," there is a most remarkable resemblance between Cros's apparatus and Ives's photo-chromoscope camera.

Now as to some other of Mr. Ives's claims, "the results of his honest labour." Take, for instance, his oft-repeated claim to be the originator of the principle of producing the three-colour records by means of the various rays which go to produce the colour sensations—a principle which he has loudly proclaimed as his own on the other side of the Atlantic. This claim is unfounded; the entire principle was fully and minutely described by M. Du Hauron in a communication to the Société d'Agriculture, Sciences et Arts d'Agen, on September 6, 1875.

Also in the same communication appear full particulars of the method of producing colour transparencies by superimposed coloured gelatine films, a process which Mr. Ives claims as his own "by priority of invention," &c., and the use of a modification and improvement on such by MM. Lumière he publicly described at the Photographic Club as "a pure steal" from him.

Again, the principle of taking the three negatives simultaneously, which he deliberately tries to construe me into acknowledging as his, is not his at all, but may be found in M. Cros's specification, and is fully disclosed by him long before the date of Mr. Ives's triumphs (?) at the Franklin Institute in Philadelphia.

As for the question of semi-transparent silvered mirrors and Mr. Ives's evident anxiety to get me to yield him the priority in those, I consider the "trick" too transparent for your readers. A reference to the context, and the mere presence of a note of interrogation after the words "his own (?)" (p. 174), would surely be sufficient to convince a person of ordinary intelligence of the ironical vein in which it was written, unless, like Mr. Ives, he had an axe to grind.

It is not true that partially silvered mirrors have ever been used by Mr. Ives, or even suggested by him, for the purpose for which I employ them, as described in my specification—*i.e.*, not only to avoid double outlines, but to have the reflecting surfaces so prepared as to accord each negative its proper proportion of light. I challenge Mr. Ives to prove that he was even aware, before he saw my camera, that such silvered mirrors could be made or used for those purposes. I do not forget what he said when he saw them for the first time in my camera. As for his sneer, that improvements in such mirrors have not originated from me, I can honestly claim that those I make are done by my own method for my own purposes, which is considerably more than Mr. Ives can say as to improvements in platinoised mirrors, real or fancied.

It seems to me, the more one examines Mr. Ives's claims, the more are they open to objection, and I imagine, if he submits them to a legal test, which, after his "courteous" letter in your last, seems the most manly course to follow, he will have to disclaim so much of his "honest labour" that there will be nothing left worth fighting for.

Touching his brilliant (?) idea of the reason for my challenging him to try to prove his claims by opposing my patent, he evidently considers it better to obtain a cheap advertisement by prolonging the correspondence than submit his case to a true test. Your readers can have little interest in a patent wrangle, and must be wearied of reiterated claims, and this, as I stated before, is my sole reason for challenging Mr. Ives to prove his words. Surely his "patent attorney," who seems so smart in evading "tricks," was competent to advise Mr. Ives that the powers of the Comptroller are not so limited as he would like the public to believe, and that there is an appeal from him to the English Courts, where he will find full justice for all his claims.

His reference to the French patent appears to me, to say the least, most unfortunate, after M. Nachet's denouncement of it on page 125, and, for all I know, his Austrian claims may be in the same list.

I am quite unscared by any "bogey" Mr. Ives may raise to depreciate the value of my instrument, or frighten purchasers. As for my methods being "retrograde," "useless," &c., permit me to inform him that the public are better judges of this than he can possibly be, while "puffing" his own apparatus. It would be much wiser for him not to proclaim the superiority of his patent rights and the uselessness of mine until he has legally had them so decided.

To sum up, I do not employ Mr. Ives's ideas, nor do I wish to make his photo-chromoscope, neither do I intend to allow him to mak my apparatus, which I think far better than his. It will rest with the public to decide between them. I will take all the risk of Mr. Ives's pretended "priority of invention," &c., and, if he attempts to interfere, or *even threatens to interfere*, with the manufacture and sale of my apparatus, I will *compel him* to submit his claims to the proper legal tests as provided by our legislature.

What more remains to be said?—I am, yours, &c.,

March 23, 1896. B. J. EDWARDS.

CHLOROPHYLL.

To the EDITORS.

GENTLEMEN,—In view of the inquiry of "W. H. G." (p. 184), I wish to call attention to the fact that I have not used or recommended chlorophyll as a colour-sensitiser for several years, because, owing to its gummy nature, it does not act well upon the gelatine dry plates now so universally employed in photography. It is the best colour-sensitiser for collodio-bromide emulsion, but one of the poorest for *gelatine* emulsion plates.

I achieved remarkable practical success with chlorophyll from leaves of "blue myrtle," otherwise "periwinkle," or *Vinca minor* (very common in America), after obtaining only very weak effects with chlorophyll from other sources. Strong, dark-coloured solutions were easily made, with alcohol, in a few minutes, and showed more absorption in the yellow and green of the spectrum than other chlorophyll solutions. It sensitised strongly for all colours, but the plates had to be prepared in a particular way, and *exposed wet*. Fresh chlorophyll from growing leaves, gathered in early summer, gave three or four times greater sensitiveness than chlorophyll which was preserved in solution by the addition of zinc powder.

Although no method of orthochromatic photography can give better results, as good results can now be obtained with less trouble by employing commercial gelatine-bromide plates (orthochromatic or "ordinary") *with special colour screens*.—I am, yours, &c., F. E. IVES.

24, *Southwick-street, Hyde Park, W., March* 20, 1896.

THE ARTIGUE PROCESS.

To the EDITORS.

GENTLEMEN,—I thought that Mr. Maskell was in no particular hurry as to this matter, as there was an interval of about seven weeks between the publication of my article and his remarks upon it. However, I had already begun to write a few further notes before I saw his letter of last week. These will, doubtless, be published in the same journal as my first observations on the process.

Kindly allow me this opportunity of stating that Mr. Maskell's supposition that "Dogberry" and I are one is not correct. I have not even the pleasure of knowing who "Dogberry" is.—I am, yours, &c.,

Ealing, W. CHAPMAN JONES.

To the EDITORS.

GENTLEMEN,—The discussions on the carbon processes without transfer will never finish if your contributors continue to make such confusion between the Artigue process and the bichromated gum process. They are both founded on the same principle, but the nature of the film and its preparations differ widely in both cases. So, when Mr. Pouncy talks about the directions given by Mr. Maskell to Mr. Benington as to sensitive coating, and uses these directions as a proof that the Artigue process has been discovered by his father, he is quite in the wrong, for Mr. Maskell's directions to Mr. Benington had nothing to do with the Artigue process, but were applied to the bichromated gum process. There are directions to be given about the coating of Artigue paper, for the simple reason that this paper is sold *ready coated*, the method and substance used in coating being kept secret by the inventor, Artigue. It is supposed that the substance is fish glue, and the method the powder box, but nobody has yet succeeded in producing a similar paper. As to the bichromated gum process, it was discovered by Poitevin in 1856. It is the oldest of all carbon processes.—I am, yours, &c.,

Paris, March 20, 1896. ROBERT DEMACHY.

Answers to Correspondents.

*** *All matters intended for the text portion of this* JOURNAL, *including queries, must be addressed to* "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 2, *York-street, Covent Garden, London. Inattention to this ensures delay.*

*** *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

*** *Communications relating to Advertisements and general business affairs should be addressed to Messrs.* HENRY GREENWOOD & CO., 2, *York-street, Covent Garden, London.*

CHLOROPHYLL.—W. T. BASFORD. Thanks; you will see we have a letter from Mr. Ives on the subject.

PRINTED MATTER ON SENSITIVE SURFACES.—W. SAVILLE KENT. Thanks; the phenomenon of printers' ink impressing sensitive surfaces is well known.

SILVERING MIRRORS.—B. ATKINSON. The formula referred to will do quite well for silvering mirrors that are to transmit as well as reflect light. The operation, however, must be stopped at a very early stage.

C. LAUDS.—By removing the centre combination of the triplet lens the focus of the instrument will be shortened, and it will, consequently, be more rapid; but it will then only cover a very small field as compared with what it does in its entirety.

CARBON TISSUE.—A. W. Carbon tissue in the insensitive state may, we surmise, be had from all the large dealers. In the sensitive condition it must be had direct from the makers, as it does not keep good for more than a fortnight or so, therefore dealers do not stock it.

COLOURING.—WALES asks: "Can you inform me of a firm that publishes a book for colouring photographs, cabinets, heads, &c.?"—All the (few) works we know of on this subject are, we think, out of print. Possibly Messrs. Newman & Co., Soho-square, may have some copies of their work left.

TONING MATT COLLODIO-CHLORIDE PAPER.—G. P. says: "I should be very much obliged to you if you would give me a formula for toning matt collodio chloride prints to make them look like platinotypes."—We know of no better formula than that the Paget Company supply with the matt paper.

LENS FOR LANDSCAPES.—W. C. P. writes: "As I understand that the front lens of a portrait combination will do for landscapes, how would one of the combinations of a Dallmeyer's patent view-lens do? Which combination would be the best, back or front?"—The lenses constructed specially for landscapes by Mr. Dallmeyer are single combinations.

VALUE OF LENS.—BEGINNER (Walworth). A half-plate portrait lens, without a name upon it, may be very cheap at fifteen shillings, or it may be dear at any price, and many such lenses are. All will depend upon its quality. We have occasionally seen lenses without a name upon them that would put some in the shade that had one upon them.

PALMER'S INTAGLIO PROCESS.—AN ARTIST READER says: "Please inform me if there is anything to prevent me from practising Palmer's Autographic Intaglio process of 1842, the patent of which is, I suppose, expired long since; and where can I see the specification of Palmer's patent?"—Nothing whatever. If the process were patented, the specification of it can be seen at the Patent Office. We have a strong impression, however, that Palmer did not patent the process at all.

FINISHING.—BROMIDE asks: "Is there any book giving instructions for finishing bromide and carbon enlargements in black and white? Does the surface require washing with a preparation before working up so as to destroy the gloss? If so, what preparation is used, and is it supplied ready for use?"—The best work on the subject was Wake's, long since out of print. The gloss on the surface may be destroyed by rubbing it over with an "ink-eraser," or with *fine* cuttle-fish powder or pumice powder.

BUILDING LAWS —STOPPED. If the Town Council has served you with notice to take the studio down on the grounds that it is against the Council's by-laws, that plans were not submitted before building, and that it contravenes the building acts generally, we surmise you will have to pull it down if it insists, that is, supposing the allegations are correct. However, we should advise you to see the Town Surveyor, and it is possible that the building may be so modified that it may be permitted to remain where it is. We should not recommend you to fight the Council over the matter, as it would be a costly affair, and your chances of being successful are remote. Better appease the authorities if possible.

SUPPORT FOR CUT FILMS.—R. W. says: "I have just been making a trial of cut films, placing them in an ordinary dark slide, with a piece of card to make up the thickness. My slides, being solid, have no rebate to them, but only buttons to retain the plates, and I have found that the film sometimes curls sufficiently to prevent the shutter being closed after an exposure. I think I could overcome this difficulty by spreading one side of the backing cards with some sticky substance, to which the films would adhere when placed in contact with. But I am at a loss as to what to select for this. It must, of course, be fairly dry, for, if too messy, it would get on to the surface; on the other hand, it must not be too hard, like black varnish or copal, otherwise, when the exposed films were packed away back to back, it would be impossible to separate them for developing; also it must retain its moist condition, so that new films will adhere to it at any time when it is desired to recharge."—In reply: Fitch, of Fulwood's-rents, supplies cards coated with a moist adhesive suitable for your requirements.

*** *As Good Friday falls next week, we shall go to press a day earlier than usual. Will our contributors and correspondents therefore please note?*

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 1874. Vol. XLIII.—APRIL 3, 1896.

Contents.

EX CATHEDRÂ.

Under the direction of Mr. J. Le Couteur, the Photographic Association has been formed, with premises at 16, Brook-street, Hanover-square, W., for the assistance of amateurs. Subscribers receive among many advantages those of instruction, development of negatives, assistance in the purchase of apparatus, use of dark room, and "free criticism of negatives." As the subscription is not very large, the benefit to the subscriber under the latter head should alone be worth the money.

* * *

Mr. W. Thomas, the Chairman of the Affiliation of Photographic Societies, writes to us in regard to the "Affiliation Lectures" already announced: "Will you kindly draw attention to the fact that it has become necessary to alter the date of the opening lecture, by Captain Abney, from the 10th of April to Wednesday, the 15th of that month, Captain Abney having to be in Leeds on the date originally fixed. All the following lectures will come on the dates fixed without alteration."

* * *

In reference to the names that have been suggested for the New Photography, Dr. David Walsh (Temple) writes: "Your late interesting editorial drew attention to the want of a comely and convenient term for what is now known as 'the New Photography.' Perhaps I may venture to suggest 'shadow type' or 'shade picture' as possible names. At any rate, the use of such expressions as 'shade printing' or 'shadow printing' a fracture, or 'a needle was shade-printed in such-and-such a position,' would be less barbarous than many of the cumbrous periphrases now springing into vogue."

* * *

Messrs. Berger & Co., of South Hill-park, N.W., manufacturers of the "Luxia" P.O.P., ask us to state that they desire to apologise to their clients for the delay in the execution of their orders. This has been caused by an accident at their works, which, however, is in process of repair.

* * *

Our transatlantic *confrère*, Dr. Edward L. Wilson, the Editor of *Wilson's Photographic Magazine*, has made his appearance before the great American public in the pleasant character of a celebrity. His portrait and biography are given in No. 6 of the second volume of *Celebrities' Monthly*, issued by the Automatic Photograph Company of New York. Maurel, Ella Wheeler Wilcox, Mdlle. Bauermeister, Edward H. Sothern, and Richard Croker are also given place in the same part, so that Mr. Wilson has the gratification of sharing his celebrity in good company.

* * *

Messrs. Eddison, Limited, gave all the employees at their various establishments at Leeds, Huddersfield, Halifax, Dewsbury, Barnsley, &c., an "outing" to Bradford on Thursday, March 26, for the purpose of enabling them to inspect the extensive new works at Grosvenor-place, Manningham-lane, which have been erected especially for the purpose of concentrating under one roof not only the ordinary printing and enamelling rooms, but also artists' rooms, and workshops, for every department of the Company's extensive and rapidly increasing business. Each department has been carefully and thoroughly supplied with every possible convenience, and with all the latest improvements and appliances for securing better work in less time and at less cost, so as to enable the Company to raise still higher the standard of excellence they have already established for themselves.

Evidently the visitors were highly delighted with all they saw, and subsequently over a hundred of them sat down to a capital dinner provided for them by the Company at Hanson's Restaurant, under the presidency of the Managing Director, Mr. J. E. Eddison. This was followed (after the usual toasts had been given, and some remarkably good songs had been sung) by a most enjoyable dance.

TO ASSISTANTS SEEKING SITUATIONS.

Whether photography be looked upon as a business or a profession, the relative number of the employed compared with the employers is gradually but slowly increasing. Forty years ago a photographic "assistant" would have been a rarity, but so vast now are the ramifications of the science and its applications, artistic and otherwise, that photography has become a most important industry. Concurrently with this uprising of a new industry have become the expensive outfit necessary to start a photographic studio or a photo-mechanical establishment, and the creation of a large body of assistants to help to carry on the various necessary branches. It is to this large body of workers, at a period of the year when their services are beginning to be in demand, that we desire to offer friendly counsel, such as, from contact with a large number of employers, we are led to believe is really needed.

Let us follow the usual course of replying to an advertisement and its results. For some time past photography has undoubtedly been in low water, and the number of unemployed is so great that, in whatever department an assistant is advertised for, a large number of replies is sure to be received, and time will be needed for the employed to wade through them. If this obvious fact were well borne in mind, much trouble would be avoided at the outset.

The first thing to be done is to read the advertisement carefully, and, in writing a reply, to be careful to give all the information asked for. If this be not done, such imperfect applications are likely to be at once rejected, as the natural inference would be that the information withheld would be of an unsatisfactory nature, and where there is, as is almost sure to be the case, plenty of choice, the employer will not waste time over useless letters. If age is asked, give it. If particulars of previous employers is wanted, supply them. Above all, when the salary required is an item in the advertisement, the applicant should make up his mind to name a sum, and not shillyshally in the hopes of driving a better bargain. Unless the applicant has something special to recommend him, such letters would be thrown aside.

Next comes a very important matter, whether to enclose a stamp for reply or not. It is not a necessity, but, as a mere matter of getting a settlement, the enclosing a stamp would, in the majority of cases at any rate, ensure an answer when the application had failed.

When it comes to a similar question with regard to stamps for return of specimens, our most urgent advice is that stamps be sent, that no loophole be left for some of the unscrupulous ones who we hear of so often retaining valuable specimens (the only means in many cases of obtaining a post), an action of such turpitude that we find it difficult to find words to express our abhorrence of.

Let us follow a number of these applications by entering the sanctum of the advertiser. If a place of any importance, there will be dozens of replies, with all sorts of packages of specimens. We have the best grounds for saying that the carelessness with which these packets have often been sent is beyond belief. Some will be perhaps tied up with a bit of sewing cotton, others more strongly tied, but packed as though they were articles of ironmongery, nothing to prevent the mounted prints from rubbing against one another, and perhaps no outside boards to protect from the post official stamp. It is the smaller moiety that is carefully and properly packed. The packages are next opened, and still more carelessness presents itself. A large number actually contain no memorandum whatever to identify them, and, if the defacing stamp, showing office of origin be illegible, pure guesswork only can supply the sender's name; and yet, whenever prints are lost under such conditions, the unhappy advertiser is branded as a cheat and a rogue.

Then, the specimens themselves. There may, in the sundry replies, be perhaps a hundred or two in the aggregate of other people's pictures, and yet we are credibly informed that not one in ten has the owner's name written upon them. It is not every employer who is a systematic business man, and, when he is not, it is easy to imagine what will happen if by any chance the contents of the packets get mixed, say, by the chance upsetting of a neatly piled set of packets. Is it to be wondered at that some masters, selfish ones it may be, throw them into a drawer and say: Let them be fetched, we will not spend our days in sorting them out, taking trouble that careless people should take for themselves? We do not say we hold with such views, but sensible applicants must take the world as they find it.

It is utterly futile and foolish to say "masters ought to do so and so," for that has nothing to do with the matter; the question to be considered is, What masters are likely to do, not what they ought to do.

Now, as to returning all these things to their unsuccessful owners. No doubt, the senders have thought it plenty of trouble to pack up their pictures "on the mere chance of getting a berth." Let them look on the other side of the question. What must the trouble be to the employer, or his assistants even, who have to return some dozens of these packets, each one to its legitimate owner? One person, working at nothing else and for ten hours a day, could not pack up pictures for, and reply to, a score or two of applicants. It is, then, little to be wondered at if his patience fails him, and again the drawer is opened for the throwing in of numbers of luckless specimens.

Very much more could be said in the same way, but we trust that what we have written will be well thought over by those who answer advertisements.

To summarise our advice, we will conclude by a few maxims for those who are seeking posts by replying to advertisements:—

1. Write legibly and to the point; answer all the queries of the advertisement.

2. Enclose a stamped addressed envelope for a reply.

3. If enclosing a "portrait of self," let the sender's name be legibly written upon it.

4. In sending specimens, let stamps for return invariably accompany them, with also a suitably addressed cover for their return.

5. Let every specimen have its owner's name (and preferably address) written plainly on some part of the picture or mount. If on the picture itself, there is little danger of dishonest persons retaining them.

6. Let every parcel be neatly packed and securely tied, and let nothing "of the nature of a letter" be enclosed in a packet sent at book-post rates.

If these recommendations are carried out, trouble will be saved and anxiety allayed.

Paper Negatives.—At one of the late meetings of the North Middlesex Photographic Society a paper was read on *Enlarged Paper Negatives*. "Its author," the report says, "told how paper negatives were made long before glass plates were in use; but the exposures for landscapes then necessary ran into hours." This is another illustration of the tendency of modern workers to depreciate the older processes without really knowing anything whatever about them. Fox Talbot's was the first negative process, and that was on paper. With it, with a portrait lens, and a fair light, a portrait could be taken in the studio in from twenty to sixty seconds. With a single lens, used with an aperture of *f*-30, and a landscape, in a tolerably good light, the exposure would be from three to ten minutes.

The wax paper, a slower, dry process in which the paper would keep some weeks after preparation, required a longer exposure; with a single lens working at *f*-30 a landscape, in a fairly good light, would require from fifteen to forty minutes according to the subject. Greater rapidity than this, however, could be obtained by sacrificing some of the keeping qualities of the paper. The old processes, it is true, were very slow, as compared with gelatine plates, but they were not nearly so slow as some modern writers, who have had no experience with them, would lead the present generation to believe. If the author of the paper that has called forth these remarks were to master the first negative process—Talbot's—he would find that little, if any, longer exposure—possibly less—would be necessary than that with the paper he is now using.

The Art World.—Artists are now hard at work in view of the different exhibitions which will open their doors within the next month or so. Already the art publications are telling us the titles of the different works that the principal painters are sending to the Royal Academy and other shows. This year, owing to the death of its late President, Lord Leighton, it has been decided to forego the annual Academy dinner. At the Welsh Eisteddfod, which is to be held at Llandudno in June, there is to be an Art Exhibition, at which it is hoped to show some 500 or so of works by living artists. An Art Exhibition is quite an innovation in connexion with the Eisteddfod, and will not, we believe, be at all confined to Welsh painters. Possibly the present innovation will be extended in future Eisteddfods to a Photographic Exhibition. Wales teems with beautiful scenery, as every votary of the camera is fully aware, and a Photographic Exhibition in connexion with this annual national gathering could scarcely fail to be an additional attraction.

The Balloon Expedition to the North Pole.—For a long time past reports have been appearing as to the active preparations that M. Andrée is making for his balloon expedition to the North Pole—the progress in the construction of the balloon, &c. Some months back, it will be remembered, we mentioned the enormous number of cylinders of compressed hydrogen it was proposed to take to fill the balloon at the starting point, and the remark we made at the time that it was rather a "tall order" for compressed hydrogen. The latest report is that the vessel, the *Virgo*, which is to take the balloon and its appurtenances to Spitzbergen, will also take between thirty-five and forty tons of sulphuric acid for producing the hydrogen for its inflation. If this be the case, we surmise the project of taking the hydrogen, compressed, in cylinders has been abandoned. If, say, thirty-five tons of sulphuric acid is necessary to produce the quantity of hydrogen necessary for the balloon, it would, indeed, have been a big order for the gas in cylinders, and for the cylinders themselves.

Plates for the Röntgen Rays.—At the recent demonstration at the Photographic Club several important points were mooted with regard to the most suitable plates for the Röntgen process without anything definite being arrived at. Authorities were quoted that there was no difference between the slow and the most rapid, also that commercial orthochromatised plates had no advantage over the ordinary, and by some that they had. Just now investigators seem to be devoting themselves almost exclusively to the improvement of the tubes and the "light," but there appears to be little done in the direction of the plates to receive the image, and their improvement if possible. Plates can now be specially sensitised for the different rays of the spectrum, and it is more than probable that they can for the X rays. We are told that two members of the Club, who are adepts at dry-plate making, have promised to take the subject in hand. A noteworthy feature in the most recent work is that the exposure has been shortened, while the results are improved. This leads one to ask whether, in the earlier ones, which were faint and indistinct as compared with recent ones, over-exposure, speaking photographically, was the chief cause of the inferiority?

Salt as a Fixing Agent.—Last week we had occasion to correct our amateur contemporary on a historical point in connexion with one of the pioneers of photography in this country. In its last issue, our contemporary says that a common salt fixing bath, the introduction of which it noted recently, was suggested by Dr. Liesegang about seventeen years ago. "He used a saturated solution of common salt, to which a little ammonia is added." As we said last week, when early events in photography are quoted, they should be given correctly, or they will be misleading to the rising generation of photographers. Common salt was really one of the first fixing agents used in photography. Fox Talbot used it for fixing his first pictures in the "thirties," and Daguerre also employed it at first in his process, but used hyposulphite of soda later on.

Ammonia, too, was one of the earliest fixing mediums. It had, however, to be used very dilute, otherwise it weakened the silver image; that was before gold toning was adopted. Later on, when gold toning was in vogue, it was strongly advocated by some. In a paper read before the Photographic Society, in 1855, by Mr. George Shadbolt, a former editor of this Journal, he strongly advocated the use of the ammonia fixing bath, and gives the proportions as one part of strong liquor ammoniæ to three or four parts of water as being suitable. Ammonia is, in many respects, an excellent fixing agent for chloride prints, as with it there is no fear of sulphur compounds being formed, and the chloride of silver is freely soluble in it. Ammonia can, however, only be used for plain paper prints, as it acts upon albumen. It is, as well, exceedingly unpleasant to use of the strength requisite. The time of fixation is about the same as with, the usual strength, hyposulphite of soda. We merely refer to these two fixing agents to point out that their proposed use is not such a modern suggestion as our younger contemporary would lead its readers to imagine.

ON THINGS IN GENERAL.

The rage for Röntgen pictures is something akin, only more so, to the furore for photographing which set in when Archer's discovery first made the science popular. The extent to which it has seized hold, alike, of the public and the photographic manipulator, expert or otherwise, is simply marvellous; there is hardly a village school whose chief has not taken Röntgen pictures and given the inevitable lecture. Any one who has had really practical acquaintance with the work knows that all the talk about a four-inch spark coil being needed is all moonshine. Properly worked, a coil, costing a few pounds only, used with Opie's medium, is quite capable of giving excellent reproductions of the familiar bunch of keys, and what might be termed the nauseating coin, if it were not that the general complaint of the photographic practitioner is that he never gets nowadays such a surfeit of coin as to create a nausea. Then, again, as to the tubes—what a harvest the tube-makers must be reaping!

Mr. Freshwater tells us that the best form is the so-called "focus-tube" of Newton, which, in his hands, and using a two-inch spark coil, gave good results with two minutes' exposure. Yet, about the same time, Mr. Gifford (who is a better authority) writes to *Nature*, stating that the best results can be obtained with the original spherical tube used by Crookes in 1879; but, using a five-inch spark coil, and a new tube of this kind, he deemed three minutes the needful exposure.

As to price, I note the first page of the JOURNAL advertises a set at 23*l.* 5*s.*, and in another place a modest couple of sovereigns will buy the needful! Many people have been wondering how it is that Edison has not been to the fore in this matter; but, according to the latest report, he has made his start. He has been experimenting with nearly two thousand substances, and at last has found one which is so fluorescent that he can see right through the structure of the human body by its aid. But he shrouds this substance in mystery, and will not disclose its composition to a single soul.

There appear to be signs of a recrudescence of an old carbon printing warfare. I say, let it go on for a while, nothing but good will follow from it. Novelties are ever looked for, and, if what is generally looked upon as a novelty has also good points, a little judicious discussion will give it a useful fillip. That there is something to be learnt in carbon printing is patent to any one who paid attention to the work at last year's Salon. There were some effects simply exquisite. I must, however, put on record my belief that a good carbon print, taken on a piece of ground glass, has a delicacy and finish all its own, and which will take something very superior to beat it.

Then we have the new Herkomer printing or engraving process, evidently possessing qualities of merit, but at a recent meeting of the Royal Photographic Society Mr. Bolas conclusively showed that there is nothing new in it, that Palmer over half a century ago described the same or a better thing; in fact, slightly to paraphrase an old criticism, "What is new is no good, and what is good is not new."

The discussion on lenses at the London and Provincial Photographic Association was one of that class that is most fruitful in information and knowledge. It was interesting to have recalled to mind Professor Piazzi Smyth's work—a monument of perseverance under conditions of extreme personal discomfort and climatic conditions in the highest degree inimical to good work. It was the "good old times" of wet collodion, which in the sultry atmosphere of Egypt, and in the dusty, murky darkness of the Pyramids, must have been as excessively trying to the physical frame as to mental equanimity. But is Mr. Dallmeyer correctly quoted? He is represented as saying that Professor Smyth got rid of curvature of the field by the use of a strong negative lens just in front of the plate. My recollection of the method is that the Professor first employed a piece of plain glass, and then improved upon it by substituting a piece which on one side had been worked to a slight concave curve. The discussion on the proper position of the stop to avoid flare was not very fruitful. Mr. Dallmeyer said there really was no rule; and that is just the way to look at it. That there really is no rule is evident from the fact that many lenses have been sent out from houses of the highest repute, yet exhibiting flare to a most marked degree. The remedy is very simple for flare when it does exist; it consists merely in altering the position to a more suitable one by the simple plan of trial and error. Of course, it involves a rearrangement of the diaphragm holder, and this is the difficulty for the photographer not accustomed to working in brass.

Mr. R. W. Craigie deserves well of his brother photographers for, after first unearthing, finally burying or leading to the burial of that old superstition that no one but a foreigner has been permitted to photograph the pictures in the National Gallery. We have it on the authority of Mr. Charles L. Eastlake that "the privilege has been accorded to numerous professional photographers both in London and the provinces." But to avoid the place being crowded out amateurs are not permitted. This is unfair to the amateurs; they ought in fairness, as taxpayers, to be able to photograph on suitable occasions by obtaining permission after sending in a special application. But I think Mr. Craigie has been travelling beyond his brief in two directions. First, in suggesting that the time and trouble required to do the work well would not be given by the professionals; secondly, in saying that copying pictures is the very work that amateurs excel in. I have never seen good amateur work in this direction. Copying paintings requires practice and knowledge, and the possession of a variety of adjuncts such as few amateurs can boast of.

I admire the calm way in which our Editor raises a smile against the *Microscope* giving a certain formula for a new ink without making a comment, but it is too good to be allowed to pass without further notice. We are directed to make an ink by dissolving shellac in half its weight of Venice turpentine, and then to stir in as much lamp-black as turpentine. The formula is an excellent one, but it possesses a slight defect, inasmuch as shellac will not dissolve in Venice turpentine, to begin with. Further, if by any means they were made to mix, the lamp-black could not be combined with it at all; and finally, if the whole three constituents could by any means be amalgamated, it might do for putty, but would certainly not do for ink.

FREE LANCE.

DIGRESSIONS.

IV.—BOGIES.

WE are all afraid of bogies, and timidity is the bane of art. It is only the strong—or the utterly incompetent—that dare the risk of being original; mediocrity does not venture to experiment, except on the usual lines; it is surrounded by bogies who take care that it shall only do what others think proper. There is this difference, however, between the weak and the strong. Originality, as a rule, comes slowly to the strong, it grows with them, it broadens down; with the weak, it usually bursts forth suddenly, and the flash quickly expires. The one produces substance, the other shadow.

Originality, from whatever source, is often set upon, and sometimes suppressed, by bogies. In photography, for more than fifty years, we have been troubled by the arbitrary bogies of right and wrong, down to the merest details of practice. There are many who prefer to discuss work than to do it. I don't say that it has not been very pleasant amusement, but half the arguments that have taken place on our art have been as to whether this or that was legitimate; whether, for instance, a pinhole may be stopped out of a negative, and, that interference with nature conceded, what may be the size of the pinhole; and I believe that tremendous problem is not yet settled. It is a similar question to the Asian mystery as to how many angels could dance on the point of a needle. A simple-minded experimentalist would have contracted for a quantity of angels, set them up on the given coign of vantage, and counted them. I believe many an otherwise good negative has been spoilt because the conscientious photographer could not decide how large a hole it would be lawful to stop.

I think it may be taken as an axiom that a new thing cannot be orthodox, and that it is absurd that a new thing must be like all others of its class; yet I remember how, forty years ago, I was roundly abused for printing a sky to a landscape from a separate negative—a thing done by everybody every day now—because it was not orthodox. The latest and funniest form of bogie is that young critic who, when writing on art, condemns combination printing, and, when working as a photographer, depends on that useful method for his effect.

Bogies of this kind, both in our mechanical practice and artistic imaginings, have come in clouds, until it culminated on the mechanical side in our being told we must expose exactly and develop with precision and by machine, and not according to the wicked will of a man with a fancy, or another who had the still further audacity to do without a lens altogether. On the art side, the bogie shook his head if we did not screw up our lenses to the concert pitch of the optician, and at one time there was a fear that the Royal Photographic Society would issue a proclamation that no photographer should be allowed to use other than a particular-sized plate, or include more than a certain angle, as by law provided, and the "turn of the screw" was as much discussed in the Council Chamber as if it was the deepest dungeon of the Inquisition. The Battle of the Standards is, I believe, still going on, the last fight being, or was lately, in progress in Philadelphia.

The astounding thing to me is how any of us, with all these restrictions, have ever made anything approaching to what we diffidently call a picture. Even some of the most enlightened still have their conventional notions of right and wrong. That great question of using more than one negative in a picture depends, in the advanced, illogical mind, upon how many. One appears to be legitimate, two or three are not.

A shocking bogie is that of criticism. Originally intended to lead, aid, and correct, it is too often used to over-praise or over-condemn. Either may or may not do good, according to the constitution of the victim; but there would be difficulties about getting a medical certificate in every case, and the critical bogie should not be too violent on the young. The neophyte is usually terribly afraid. It takes him a long time to find that even the best of its kind is not supernatural, after all, and that the bogie is only a turnip lantern to which the electric light has not yet been fitted. A terrible disillusion, out of which, however, if taken philosophically, some fun may be got, if not much knowledge. But to the healthy, mature mind all criticism is good (except the fulsome), just and unjust alike. Just criticism is sure to teach you something, unjust to set your back up and put you into fighting trim. It is the morbid mind that suffers, and the timid that is afraid of being true to itself for fear of doing sixpennyworth of temporary damage. After all, the best way to meet any kind of criticism is to do better work.

Then, the critics themselves in their turns have their bogies. Some critics may be greatly pleased with a picture, but, not knowing how it is done, dare not give themselves away by stating opinions of their own. Few dare say, as I say now, that I have often found myself at the top of this particular tree. I often find that I am asked for information on a subject of which I know nothing. I find it best to face the music and confess ignorance. "The courage of his opinions" is a good phrase for something very rare, in both meanings of the word "rare."

Questions on some subjects about which I know everything puzzle me to answer more than the more recondite. As I write comes a letter from a quarter-plate instanto amateur, asking me if I pose my figures myself, and if I do them instantaneously. I can only reply by asking him if he thinks I am a fraud, and if he will kindly define the word "instantaneously." Then those dreadful handbooks give one no end of trouble. Here is a question just received, "Do you consider you can take a satisfactory snap-shot in the shade? One book says you can, and another says, Always take them in full sunlight?" I take the opportunity of hereby solemnly declaring that I don't know, and, further, that I don't know the least bit of anything that is to be found in a technical handbook; and, if I did, it would cost me a great deal more to write than the inquirer to read. These be my present harmless unnecessary bogies, a little troublesome at times, but, after all, they repay cultivation, and I would not be without them.

The bogies sometimes gather together in great force for a combined purpose. The last occasion was when obstruction or vested interest took them on as mercenaries to hinder, or perhaps frighten, the Salon out of the field, but the Linked Ring turned on the searchlight of "Art and Liberty," and the bogies, like the Boojum, "softly and suddenly vanished away."

The result of the last dispersal is that the art photography of the world is now vastly improved, and the Salon is recognised as the centre of the art photography of the world. The minor exhibitions of England have improved, although still greatly hampered by those who have their own axes to grind. Then, there is the hanging bogies. The Royal Society last year had some good pictures sent in, utterly spoilt, however, by the worst hanging any pictures were ever subject to. Why does not the Society recognise its deficiency in this respect, and employ an expert from the Linked Ring, as it does its Judges? The good of the art should be the one thing looked to, nothing smaller.

Another improvement is that photographs are not now judged by line and rule. It is true that many exhibitions are still minutely divided into classes—that is done for business reasons—but a man may now produce a picture about which even he himself has to look on the back before he can truthfully say which is top or bottom without producing a smile or a mild witticism. Compared with the past this is liberty indeed, and, as usual, freedom is not abused. I had forgotten the *Cricketer* in the last Salon when I wrote this. I don't think that the most blundering critic will confess to seeing more than three or four photographs a year of which he could not make head or tail; but most critics have more to say of pictures of this kind than of those which are intolerably sane, and they should be grateful for something to write about. Would it be very wicked to say these pictures suit them best?

And, indeed, it is only the superficial observer who never sees the use of the bizarre, the eccentric, and the out of the common. There is sometimes great wisdom in foolishness. Those who see deeper say, as Goethe said to Bettina, "You do not utter one word of sense, but your absurdities teach me more than all the wisdom of the Greeks."

I am reminded by the late Cheltenham Exhibition of another bogie. The particular bogie I am about to mention is of the most malignant kind, and makes all exhibitors shiver.

There are many good reasons why some photographers do not care to lend their pictures to exhibitions. They have little or nothing to gain; there is, it is true, the bare chance of a picture being sold, but this chance, if it comes off, seldom pays for carriage, for damage to frames, and other expenses; the quantity of classes and medals compel those, with any self-respect, to exhibit "not for competition." This is bad enough, but the bogie to which I want to draw attention is the carpenter fiend. Having had much experience of this gentleman, I now have a large label fixed inside the lid of my case, by way of a hint to the packer, to this effect:—

> IN RETURNING, PACK AS SENT.
>
> SCREWS ONLY TO BE USED.
>
> NO HAY, STRAW, OR PAPER RUBBISH TO BE EMPLOYED.

This seems to have irritated the Cheltenham bogie worse than usual, for, although my frames and case are made to pack almost automatically, and a small bit of wood fixes everything, the malignant demon stuffed the case full of dusty straw, which compelled me to send the pictures to the frame-maker to take out and clean, while instead of the necessary half-dozen screws, to fix the lid, a quantity of enormous wire nails were used, so that the cover had to be removed in fragments. Now, I have every reason to know that the Cheltenham, although its first, was one of the best managed of provincial exhibitions, and I have nothing but praise for the admirable Honorary Secretary, but I take great pleasure in anathematising the Cheltenham carpenter fiend, and hope that, when this thriving Society has another Exhibition, there will be some promise of a packer who knows his business. This, unfortunately, is not a singular or personal matter, and all exhibitors who have suffered loss will be glad to have attention called to it.

H. P. ROBINSON.

BY THE WAY.

IN what must be considered an incredibly short space of time the new science of radiography, as I suppose we must at present call Professor Röntgen's discovery, seems to be settling down into conditions of practical utility, and, though we must expect for some time to come a continuance of the sensational and exaggerated statements that are daily appearing in the "lay" press, there can be little reason to doubt that ere long it will be found to have taken up a fixed position of actual usefulness. In my last notes I alluded briefly to the first advertised "installation" of the necessary apparatus for the production of radiographs in a commercial way, that of Mr. Friese Green, and, though this, I think, rather aimed at satisfying the curiosity of scientific or pseudo-scientific *diletantte*, it is interesting to note that in the interim other gentlemen have taken

up the matter in a thoroughly businesslike way, with a view to bringing the benefit of the process within the range of practical surgery.

Naturally, in the course of time, we may expect further improvements in the working details of the method, more especially in the direction of more powerful and more reliable sources of the new power. At present the production and maintenance in working conditions of the vacuum tubes appear to present the chief difficulty, while the refusal of the new radiations to conform to the same laws as ordinary light rays in the way of refraction and reflection limits, to a very great extent, the degree of perfection obtainable in the results. In these directions, I repeat, we may in time find important advances made, but in the mean time we may also expect to find numerous experimenters in divergent channels, as, for instance, in the direction of altogether dispensing with the more elaborate items of apparatus involved in the production of the original "Röntgeographs."

Salvioni's cryptoscope seems to be the most important step up to now in the extension of the usefulness of Röntgen's discovery, for, although it requires to be used in conjunction with the more delicate apparatus for the production of the radiations, it displaces the photographic plate, and so does away with one of the uncertainties of the method, the estimation of the correct time of exposure. Naturally it gives no permanent record of observations, unless the camera be used in addition, in which case it becomes a complication; but, in the hands of a skilled observer, and especially for surgical purposes, and under conditions where the application of photography is difficult, or even impossible, it seems likely to afford a much wider scope of utility. For instance, in the operations of "probing" for objects buried in the tissues, or of examining or searching for defects in bone structure, the continuous ocular observation by means of the cryptoscope seems to offer far greater convenience than the making of successive "shadowgraphs," with the attendant expenditure of time and the uncertainty as to exposure; and, moreover, without doubt to the practised eye, the direct observations would have a greater significance than the shadows produced on the photographic plate, which must naturally vary in character with the exposure given.

Such experiments as those recorded by Mr. G. Scorah, at p. 175, are undoubtedly interesting, but they only differ in result from the original "radiography" in requiring a longer exposure, and presenting greater uncertainty in their production. But they certainly may be fairly taken as raising the question, propounded by your correspondent, Mr. F. W. Muncey, a fortnight ago, as to what may be considered as constituting a safe packing for sensitive films. There must, theoretically at least, be a limit to the opacity of every material to the passage of extremely powerful light rays, though, in practice, it is not difficult to keep within the bounds of safety. For instance, an ordinary dark slide may be perfectly safe, and so may a dark-room window in diffused light or with a comparatively slow plate, while either will break down completely in sunshine. The ordinary methods at present adopted by our plate-makers, in packing their sensitive films are, no doubt, quite efficient under ordinary conditions of storage; but it does not, under the revelations of recent science, look as if it would be a safe proceeding to leave a box of plates with all their wrappings on, for even a few minutes, in full sunshine.

I am not sure that I completely comprehend what is meant by those who claim that "shadowgraphs" can be produced in complete darkness—so called—*vide* Scorah's letter above referred to; but it seems to me that the claim is that all objects are endowed after exposure to light with some species of fluorescence, possessing penetrative powers greater than those of ordinary light rays and akin to the Röntgen radiations. If that is the case, it seems impossible that any mode of packing can be absolutely safe unless the materials used be stored in absolute darkness for a long period before use. I know in the earlier days of gelatine plates it was suggested that certain kinds of fog and markings were due to the fluorescence or phosphorescence of the packing paper employed, but I do not remember that the fact was ever actually established. I remember also a friend trying to demonstrate to myself and others the possibility of photographing—with a rather long exposure, of course—through a thin sheet of ebonite. But the mystery disappeared suddenly when one of the party, holding the ebonite close up to a gas flame, showed that it was *transparent* enough, not merely *translucent*, to show the shape of the flame with perfect distinctness.

Somewhat of the same nature is the effect alleged to have been obtained by Mr. Ingles Rogers with the retinal impression, produced by gazing long and fixedly at a postage stamp, and then placing a sensitive plate in the same position as occupied by the stamp. But, whether it is possible to so produce an image or not, the idea is not new, for I think it was Mr. Friese Green who some years back tried to demonstrate before the Photographic Society the fact that the retina, after exposure to a strong light, became luminous or retained for a time some of the luminosity absorbed. As it was reported to me, the lights having been extinguished in the room, the demonstrator submitted his own eye or eyes to the glare of burning magnesium, and then, facing the crowd in the dark, asked, "Can you see me?" As the only reply from one of the members present was "I can *smell* you," it would seem as if it must have been a case of *non est demonstrandum*.

Turning now to another matter referred to in my last notes which has elicited some correspondence since—the Artigue process or carbon printing without transfer—I will take M. Demachy's letter in your issue of 13th ult. I hasten to assure that gentleman that I am far from wishing to mislead the public in regard to the results obtainable by these methods, and I think I tried to make it clear that for certain purposes I fully recognise the possibility of getting good results. I will even go further, and say that, in careful hands and under the guiding spirit of an artist, I have little doubt really excellent results may be obtained, for what cannot be effected with perseverance, care, and a love for the work in hand? But, I must repeat, the perfect image can only be obtained by development from the back of the exposed tissue, and that in the same careful hands a better result would accrue, with less trouble with transfer than without. M. Demachy, I notice, in a second communication in last week's issue, draws a wide distinction between the bichromated gum and the Artigue processes, though he claims, as I take it, that equally good results can be produced by either. As my previous remarks had reference solely to processes on the principle of the former, and not to any such modified methods as that he attributes to the Artigue in his last letter, I will take them separately.

In the strictest sense I was perhaps wrong in likening the results to scene-painting, for that involves roughness, boldness, and, above all, contrast, whereas in a process based on the lines laid down by M. Demachy—"fine colours, thin coating, and smooth paper"—contrast and boldness are the two qualities above all others I should consider impossible, but in this place I should expect "*flatness*." In the first place there is not a sufficient body of colouring matter present to give contrast except between the deepest shadows, supposing the whole of the film to be rendered insoluble, and the highest lights, supposing it all to be removed or dissolved, while there is no theoretical explanation for the presence of any half-tones. The action of the light takes place from the surface downwards, and in an extremely thin layer, if the particles of colouring matter are "separate from, and not one on top of, another." As described by Mr. Maskell at page 156, that action will take place equally wherever it occurs at all, that is to say, the film will be rendered insoluble to the same depth in both shadows and half-tones. Even supposing the layer of colouring matter to be broken up into a semi-crystalline or granular form, as suggested in an article by Mr. W. B. Bolton last week, the granularity will be uniform in both shadows and half-tones, and, assuming the film to consist of a layer of single particles, there will be no distinction between the two. It is, however, impossible to suppose this to be the case practically, for the very existence of any gradation depends upon the film possessing an appreciable thickness that enables the light to act to different depths, and then we have to trust entirely to the skill and care of the operator to successfully remove the soluble portions from the porous film.

M. Demachy appears to labour under some misapprehension in his

allusion to the "harrowing details" of "every separate eyelash, and each individual freckle." These are not the details that present any difficulty in rendering—at least, from a theoretical point of view—since they present merely fine lines or specks of colour which can easily be left on a perfectly white ground from which every particle of the unacted-on film, has been removed. The difficulty will be found in the delicate rounding of a plump cheek or the ripple on a mass of golden hair, and to combine these with the necessary depth of deposit to form the shadows of a well-contrasted picture is where the bichromated gum process, as he refers to it, falls short of *any* transfer process. I remember being struck, many years ago, by a remarkably fine specimen of carbon work, or Woodburytype, I am not sure which, but it matters not, as they both recognise the principle of development from the back of the exposed tissue. It was from the studio of Reutlinger, and represented an actress in a handsome white moirée antique skirt, with lace and embroidered trimming, every marking or "harrowing detail" of which was most wonderfully rendered. The gum process without transfer would, no doubt, be able to cope with the lace and embroidery, but it would, I fear, prove hopelessly incapable of dealing with the delicate gradations of the moirée.

My recollection seems to have misled me, with regard to the late Mr. Pouncy's process having been used only for enlargements, but the specimens I have seen were all of large dimensions. I, however, accept Mr. Pouncy's correction, though I cannot help thinking that his comparison of such work, produced thirty-eight years ago, with modern platinotypes, from the same negatives, rather suggests that the negatives cannot be suitable for the modern process. His remark anent the deep blacks of the Pouncy prints being blacker than in the case of platinotypes is quite in agreement with my own view, for the weak point, or one of the weak points, of the early non-transfer processes was that, if they possessed any details in the lights, their shadows were, as my old friend, Traill Taylor, once described it, too "diabolically black."

With regard to M. Demachy's description of the supposed method of preparation of the Papier Artigue Velours there is far more reason to believe in the possibility of really first-class results from such a process than from bichromated gum. Here the colouring matter is *on the surface* of the bichromated vehicle, whether it be gum, gelatine, or fish glue, and it becomes more or less firmly attached to it in proportion to the action of light. A similar action is found in the ordinary dusting-on process, which is a non-transfer method in the sense that the picture is formed on the exposed surface. Here the longer the exposure the deeper its effects *in* the film of sensitive material; but the difference between the two is, that in the film containing no colouring matter its attraction of adhesiveness is gradually lessened, while in the Artigue film, with the colour already *in situ*, the cohesion is gradually increased, and so reverse results, though equally in gradation, are produced. Somewhat similar results were obtained thirty years ago by floating the back of ordinary albumen paper on bichromate of potash, drying and exposing albumen side to the negative, "dabbing" with printers' ink or dexterously washing with liquid Indian ink, and then developing in cold or tepid water. A moderate degree of half-tone was obtainable, but the difficulty was a "smudginess" in the lights and half-tones.

And now a last word to assure Mr. Alfred Maskell that I am far from wishing or intending to rank him with the ordinary run of "pinholists and fuzzytypers." Far from it. I have had the pleasure of meeting Mr. Maskell, and discussing with him the very subjects we are now "on," and found him always a very earnest and enthusiastic, if, from my point of view, slightly mistaken, gentleman. I have seen several of his productions that no one need be ashamed of, as well, I must admit, others that tended to prove his "mistakenness;" but the former class have gone far to reconcile me to the belief in the possibility of getting good results without transfer. I allude now to the gum process, already referred to and described by him in detail; the Artigue process, it seems, must come under another head altogether, if it be as described by M. Demachy. And I must corroborate Mr. Chapman Jones in his statement last week that he is not identical with, and has no connexion with, the individual who signs himself

DOGBERRY.

UNDER WHAT CONDITIONS ARE SILVER PRINTS LIABLE TO FADE? *

SULPHUR emanations are nearly always present in the atmosphere, be it as plain hydrogen sulphide or as more complex compounds. Therefore it is rather difficult to keep silver ware in bright condition. Imperfectly purified illuminating gas, burning coal, decaying matter, &c., are so many sources which bring sulphur into the atmosphere. The action of hydrogen sulphide on silver prints may probably be helped by the simultaneous presence of ammonia or humidity. All other conditions which favour chemical action hasten also the process of fading. Amongst these favourable conditions I should mention increase of temperature and extreme division of the reacting bodies.

The action of heat as an accelerator of chemical reactions is so well known that I can dispense with insisting long on this point. A great number of chemical reactions will not occur at a low temperature, but will proceed easily if the temperature is increased. The influence of the state of division is accepted by all students in chemistry. Where gases act upon solids, this action will be rendered more immediate and more complete if the solid has been reduced first to an impalpable powder. Where a solid piece of iron may last for centuries, even when exposed to damp air, this same quantity of iron in the shape of filings will degenerate quickly into a brown, rusty powder. Chemists know of a method of producing iron in a shape much more divided and much finer than the finest iron filings, so fine, indeed, that it could not be obtained by mechanical means. In this glass tube I have some such finely divided iron. You will notice that this glass tube has been closed by melting it at both ends. This precaution was absolutely necessary, because this divided iron is so susceptible to chemical changes that it would combine instantaneously with the oxygen of the air and undergo spontaneous ignition.

As soon as I break this tube and scatter its contents into the air you notice that each particle of iron becomes incandescent, and, by gathering some of the products on this white plate, you will notice that these particles have acquired a brownish colour, which is the colour of iron oxide.

This example will enable us to understand how silver, in a more or less divided state, will be more or less liable to undergo the action of chemicals, and specially of hydrogen sulphide. Let us add at once that the photographic image is made up of silver in an extreme state of division.

There are many substances which, although having absolutely the same chemical composition, can exist under two or more modifications of entirely different properties. There is an element, for instance, which is known under the name of phosphorus, and which enters as chief ingredient into the manufacture of lighting matches. This phosphorus is known under at least two different states, which are designated by chemists as allotropic modifications. Phosphorus, in its usual condition, is transparent, colourless or slightly yellow, brittle when cold, but soft at summer temperature, and it melts in hot water; it is a great poison, is soluble in carbon disulphide, and has such an extremely great affinity for oxygen that it enters quickly into spontaneous combustion when exposed to the air. That is the reason why it has to be preserved under water. Now, there is another allotropic state of phosphorus, which can be produced by certain methods. In this state phosphorus is red, hard, insoluble in carbon disulphide, not poisonous, it melts only at a relatively high temperature, and can be kept without the slightest danger, even in a dry condition, as it will only take fire at a relatively high temperature. It shows none of the strongly accentuated chemical properties of the white variety of phosphorus. Silver, just the same as phosphorus, can exist under several allotropic states. This explains why one kind of silver image may prove much more permanent—*i.e.*, much more resisting to chemical influences—than the other.

The silver precipitated by development in the image of a bromide print or a bromide plate is, then, in an entirely different condition from the silver in the image of a printing-out paper. If we examine the image of a bromide print or bromide negative under the microscope, we find that it is composed of a multitude of little silver particles, very distinct in shape and of measurable size. If, however, we examine, under the same magnifying power, the image of a printing-out silver paper, we fail to observe distinct silver particles. The whole image seems to be formed by such extremely thin particles of silver that they appear more as a homogeneous stain. I have some doubts whether the printed-out silver image can be compared at all to the image of a bromide print, or any other print obtained by development. Whereas we are sure that in a bromide print the image is formed by the juxtaposition of particles of

* Concluded from page 83.

pure precipitated silver, it is very probable that in printing-out papers the process of production is not so radical, and what is called commonly a "silver image," for albumen, gelatine, or collodion paper, is probably nothing more than a darkened organic silver compound, a product of partial decomposition of the original chloro-organic silver compound. Were this image the same as a bromide image, plain fixing in hypo ought to produce a print approaching a degree of permanency somewhat similar to that of a bromide print, and experience shows that this is not so. Even the process of gilding—*i.e.*, toning—does not succeed in making it as permanent as a bromide print. The natural conclusion is, that either the printed-out image is not pure silver, or, if it contains any metallic free silver, it exists there under a special allotropic modification which is so easily affected by chemicals that it is rather liable to fade. In a printing-out paper the image has so little resisting power that even water will act upon it. Indeed, it is a known fact that such silver prints, even when they are toned and fixed in separate baths, will be affected by water, and bleach out by-and-by if left washing too long.

Far more are they liable to undergo these changes if they are toned in combined baths, as can be readily proven by direct tests.

Why is this so? It is generally stated that the lack of permanency in combined-bath prints is due to the fact that the prints have become sulphurised, and that the silver has become sulphide of silver. If this was the only reason, I fail to see why bromide prints, toned in hypo-alum, and which have been integrally transformed into sulphide of silver, prove to be very permanent, and can easily compare in this respect with the best of prints made on albumen and toned with gold.

In a printed-out image the layer of silver is either so thin or in so delicate an allotropic condition that, in order to render it somewhat resisting, it has to receive a deposit of gold or platinum. By sulphurisation such an image can only be made still less resisting, and rendered more liable to further alteration or fading. In a bromide of silver print this is not to be feared so much, on account of the more resisting qualities of the silver therein.

It may be also that, in a printing-out paper, the sulphurised image is not pure sulphide of silver, but a sulphur organic compound of silver, more apt to change than would be, under some circumstances, pure sulphide of silver. In fact, we know that silver sulphide is a product which stands very well the action of chemical agents, and which can only be dissolved in some strong acids. In nature we find it as a mineral under the name of Argentite, and in this state atmospheric agents have no influence on it.

All this points out once more that there is a radical difference between a developed and a printed-out silver image. This is further corroborated by the fact that bromide prints can stand better small quantities of hypo which may remain accidentally in the fibre of the paper. As a rule, they are more refractory to chemical agents; they are not easily affected by hydrogen sulphide. A remarkable fact is that bromide prints may be permanent even when toned in a sulphurising mixture of hypo and alum. I wish to add here that different kinds of bromide emulsions behave very differently when exposed to the action of hypo-alum. Some such emulsions will tone in less than an hour, while others will require a day or more. I have observed that slow bromide papers tone much easier than quick bromide papers. By observing the "easy toning" papers under the microscope, I found that their images have very small particles of silver, while the slower toning ones show a coarser grain. Here is a very striking confirmation of what I said before in regard to the relation of the size of the silver particles and their relative permanency.

Coming back to the question of combined baths, I ought to say, in mentioning the evils referred to, that there is to be added another one, *i.e.*, the lead salts. These lead salts are added to the mixture in order to make sulphurisation more regular by a rather complicated chemical process. But the lead salt fastens itself in the tissue of the paper, and no amount of washing can remove the last traces of it. The ultimate result is that the whites of the print will darken by-and-by, because the lead salt, under the action of hydrogen sulphide, will produce lead sulphide, which is black or brown.

In regard to the vehicle which carries the print in a printing-out paper, I have come to the conclusion that it matters little whether it is gelatine, albumen, or collodion. Endless discussions are still going on as to which kind of prints is most permanent. It has been said and repeated that gelatine is not as staple a product as nitro-cellulose, which is the basis of collodion. To this can be readily answered that gelatine has proved beyond doubt to be a trustworthy medium, and will give permanent prints. Bromide prints, bromide plates, the carbon process, and the Woodburytype process have given it a record of reliability. We know, furthermore, that gelatine in a hardened condition withstands victoriously humidity and friction. A collodion print, on the contrary, is much more liable to abrasion. The film which carries the silver image is necessarily thinner, and the quantity of silver which can be introduced in a collodion emulsion is very limited as compared to a gelatine emulsion. A fair amount of silver is necessary to give body to the print, and if the print lacks in silver it will fade much quicker, even if it is toned with gold or platinum. I am not aware that since the introduction of collodion papers anybody has ever reminded us of the fact that, under certain conditions, nitro-cellulose is liable to undergo spontaneous decomposition. I am just now in possession of quite a large sample of nitro-cellulose, which was made for collodion paper purposes, and which was offered to me by a reliable firm; after keeping it a few months it showed already, in an unmistakable way, the presence of nitrous vapours. This spontaneous decomposition of some kinds of nitro-cellulose is a fact well known to many old photographers who made their own collodion. In how far this spontaneous decomposition of nitro-cellulose may occur in collodion prints has not yet been determined accurately. If it really occurs, the resulting nitrous gases would undoubtedly prove very destructive to the silver image, and help the fading thereof. Except in such an emergency as that above referred to, we can accept the conclusion that gelatine, albumen, or collodion, may all yield permanent prints if properly handled and toned in separate baths. A good thick image, rich in silver and toned to a deep purplish purple, with a fair amount of gold, will prove to have the best lasting qualities.

The fact that a printing-out paper requires little gold to be toned makes the permanency of such prints already questionable. Thorough fixing and washing should, of course, be adhered to. I must say, however, that there is a limit to the time of washing which should not be exceeded. When this limit has been reached, any further stay in water will only lower the quality of the prints. Any paper should be thoroughly washed in one hour provided the water is changed frequently and the prints kept moving all the time. The fading of combined-bath prints has often been ascribed to imperfect washing, and yet it is a noticeable fact that such prints will become worse and worse by being left too long in the water, especially if the water is warm.

Any perceptible amount of hypo, if left in printing-out papers, will quickly affect the image, and will destroy it by-and-by. Bromide prints are not so sensitive to traces of hypo. I know of one instance where a firm, in order to rush out its orders on bromide prints, had to limit the washing very much. The result was that a notable amount of hypo was left in the prints, so much, in fact, that by the tongue any one could easily detect a very pronounced hypo taste. These prints have been made now more than a year, and I must say that they have stood the test of time very well. I wish to add, however, that I should consider such imperfect washing rather reckless, even for bromide prints.

And, now, what is the easiest method of testing the relative permanency of prints? As said before, hydrogen sulphide in the atmosphere is the agent most destructive of silver prints. After more or less time its action will be more or less apparent. In order to find out how prints are going to behave, we may subject them to an atmosphere saturated with hydrogen sulphids, and accomplish in this way in one hour what otherwise would only be determined after a test of several years.

Hydrogen sulphide can easily be produced by pouring some acetic acid on a piece of potassium sulphuret. This latter chemical is well known to all photographers, who use it for precipitating their silver from their waste hypo.

The only drawback to this hydrogen sulphide method is the noxious smell of this gas. Therefore the test should be performed outdoors, where nobody will be incommoded by its disagreeable smell. I ought to guard you also against the possible danger of spoiling your silvered paper or dry plates by the emanation of this gas. Select a wooden box, relatively tight, and provided with a cover. Take all the prints which have to be compared, and have them all under the same conditions, *i.e.*, they should either be all mounted and burnished or not mounted at all. Cut each print in two, keep the upper half for future comparison, and place all the lower halves upright against the walls of the box. In the centre of the box place a tumbler with a piece of sulphuret in it about the size of a hickory nut, then pour some acetic acid on, and cover the box at once. Leave the prints in this box for about half an hour, and examine them from time to time.
